Metallurgical and Chemical Engineering

A Consolidation of
ELECTROCHEMICAL AND METALLURGICAL INDUSTRY and IRON AND STEEL MAGAZINE

Vol. XVII NEW YORK, JULY 1, 1917 No. 1

PUBLISHED SEMI-MONTHLY ON THE FIRST AND FIFTEENTH OF EACH MONTH BY THE

McGRAW-HILL PUBLISHING COMPANY, INC.

JAMES H. McGRAW, President.
J. H. McGRAW, JR., Secretary. ARTHUR J. BALDWIN, Treasurer

239 West 39th St., New York.

TELEPHONE, 4700 BRYANT. CABLE ADDRESS, METCHEM, NEW YORK
ROCKY MOUNTAIN OFFICE.....401 Boston Bldg., Denver, Col.
PACIFIC COAST OFFICE.....Rialto Bldg., San Francisco, Cal.
CHICAGO OFFICE.....Old Colony Building
CLEVELAND OFFICE.....Leader-News Building
PHILADELPHIA OFFICE.....Real Estate Trust Building
LONDON OFFICE.....Hastings House, Norfolk St., Strand

E. F. ROEBER, PH.D., Editor.
S. FISCHER, PH.D., Western Editor.

J. MALCOLM MUIR, Manager.

Yearly subscription price for United States, Mexico and United States dependencies, $3.00; all other countries, $4.00.
Single Copy 25 Cents

When change of address is ordered, the NEW and the OLD address must be given. Notice must be received at least 10 days before the change takes place. No back copies for more than three months.

A Charming Human Document

At the last New York City meeting of the American Institute of Mining Engineers in one of the iron and steel sessions the feature overshadowing completely in human interest the balance of the proceedings was a contribution to the discussion of one of the papers. It was made by Mr. Alexander E. Outerbridge of William Sellers & Co. of Philadelphia on experiments carried out by him many years ago on the growth of certain iron castings. Mr. Outerbridge spoke at length and really upset the schedule of the whole meeting, but he fascinated his audience and received an ovation. What was an old story to him was all news to his hearers. We fancy that Mr. Outerbridge's paper on "Metallurgical Processes in the Foundry," published elsewhere in this issue, must have had a similar enthusiastic reception when presented before the Philadelphia Foundrymen's Association. There is an incomparable delight in hearing a nestor of an industry speaking modestly of his work of a lifetime. And Mr. Outerbridge's paper is a charming human document. The American foundry industry may be well proud of its achievements and of the American metallurgists like Outerbridge who produced them. And then it is always pleasant to be reminded again and again how many real good things have come to us from quiet, unassuming, industrious Philadelphia. Two-score years of metallurgical life in Philadelphia are recorded in the paper.

Steel for War

When we entered the war there were predictions that the Government would require 5 or possibly 10 per cent of the steel output. The president of one of the steel companies, who seemed to employ an unnecessarily large factor of safety, asserted that the requirements would not amount to 20 per cent. Now there are estimates running as high as 40 or 50 per cent.

A bewildering mass of requirements in steel has accumulated already and perhaps the end is not yet. In the case of most of the groups of requirements there is not even a tentative estimate of the tonnage of steel involved, particularly in terms of the rate of output. For instance, to build ships of 3,000,000 gross tonnage there has been a rough estimate that 1,000,000 tons of plates and 300,000 tons of structural shapes will be required, but the 18 months' time in which the ships are to be built is purely a guess, and therefore the proportion of the steel output involved in 1,300,000 tons is not known. It would be between 2½ and 3 per cent if the deliveries were spread equally over a period of 18 months.

The steel required in building sixteen cantonments,

cities for 40,000 inhabitants each, might be thought to run into large tonnages, but it seems the total will be only a few tens of thousands of tons, and when the work is completed, in a very few months, there will perhaps be no more required in that quarter. In other construction work, such as of hangars, shipyards, etc., the tonnage of steel will be much larger. A report that circulated some time ago, referring to 200,000 tons of steel for hangars, received little credence, but in the light of later information the estimate does not seem unreasonable.

In the case of much of the war activity there is a replacement in form rather than in substance. Thus the Government will probably order a large number of freight cars and locomotives, which in normal times would be bought by the railroads direct. The railroads have not been heavy buyers, partly on account of prices asked and partly because the car and locomotive shops could not secure full supplies of steel. The Government can take a hand and control both prices and deliveries. The car shops, which for months have been working at only about half capacity may eventually be working at nearly full capacity.

As to the shell requirements of the Government, the only important steel buying thus far has been 81,000 tons for 9,000,000 3-in. shrapnel and high-explosive shells. Much larger tonnages will, of course, follow.

In 1916 the steel exported directly to the Entente Allies or consumed in manufacturing wares for them amounted to between 15 and 20 per cent of our total steel output. The remaining exports, perhaps 5 per cent, went to neutrals. Exports to neutrals are, of course, practically shut off. If our Government buys more largely for the Allies than they did last year their proportion may be 20 or 25 per cent, and if ours were the same the total would be 40 or 50 per cent. The remainder, for ordinary consumption in the United States, would be 50 or 60 per cent, against 75 or 80 per cent last year, no great change after all, particularly considering that the percentages now refer to a somewhat larger steel making capacity. In view of the facts that commercial building on a large scale is likely to dwindle to insignificant proportions, and that much shop capacity to work steel into finished forms will be diverted from private to Government work there is no safe ground for assuming that steel will continue to be as scarce as it is now.

The Art-Science Divorce Scandal

In the cheerful days when Rembrandt van Rijn arranged, had, and from a reasonable distance enjoyed his own funeral and then watched the prices of his pictures soar; when Frans Hals would sober up now and then and dash off an immortal canvas with thirst driving him to short-cuts that to this day painters strive after at hard labor; when Jan Steen would not listen to the voice of propriety but chortled with unholy glee whenever a drunken row began—and painted it, artists "went in" for science. They kept linseed oil for fifty years and more and were very careful to select and grind and mix their own colors. They clung to renaissance traditions, but the traditions were sound—as witness their canvasses to this day. Later painters experimented without the vision of the research mind, and their canvasses show their frequent errors. It is not always wise for the uninformed to try experiments. Then followed the trade of color making as a thing apart from painting, and the painters lost interest in it. Chemistry has come into the paintmakers' trade, but artists, as a rule, do not know or care about it. They buy by label and discuss the qualities of Permanent Green, for instance, without knowing what it is made of.

Science is not welcomed into art any more. Somebody always fears that it is too material and that the artist's gift of the vision of beauty will fade away if he but knows the substance of the materials he uses. Of course, if his artistic sense is so frail that it will wither in the face of needful knowledge, it goes without saying that it is not robust enough to make a real artist of him. In a very distinguished company, not long ago, the deterioration of the work of a well known artist was considered during an informal discussion on landscape painting. A modest member of the company ventured the suggestion that the particular painter's geology was defective; that his later imaginative work was based on a series of geologic sequences that went backward. He was immediately taken to task for demanding that any painter should engage in a study so disturbing to his work and so contrary to the spirit of his task. The others were unanimous in denying any worth in his contention. Why on earth should a painter of landscapes know anything about geology? The surroundings were beautiful and the company distinguished and learned in the humanities, but the conversation was not enlightening. The instance of a figure painter was mentioned who studied anatomy diligently and yet who did not paint well, and it was claimed that the knowledge of geology cannot aid in the enjoyment of a landscape. Such were the pearls of thought contributed.

No, science has not yet been welcomed back into art. And because of this divorce proceeding men of science are occasionally found who are rather deficient on the artistic side. The cry is persistent that many good engineers lack the art of expression, and the complaint is well founded. The demand is not that they shall be able to say nothing at all with elegance and style, but rather that when they have something to say, they be able to say it. The other day there was a meeting of classicists at Princeton at which the two old idols of culture, the Greek and Latin languages, were glorified all day long as the only leaders into the graces of life. Now we know that this is not true and that compulsory classics do not make a man competent to say what he means. It is his habit of thought that gives him this, induced by training and experience in saying and reading things that are difficult to express, told with the exact, precise shade of meaning desired. This it is that gives him his intellectual background. The trouble with men who have scientific thoughts and pipe-fitters' methods of speech is not that they have failed in having been

"put through" Latin or Greek. Their trouble is more likely to be that they have graduated from local newspapers and monthly and weekly periodicals that will print any kind of idiotic pap to increase their circulation, over into physics and chemistry and mathematics. They have not engaged in refinement of thought in any language before beginning with science. And science is new, it is without traditions of expression, so that it is much more difficult to tell of reactions and processes than it is to write a sonnet. Anybody can write a sonnet; all he needs is a rhyming dictionary and the resolution to use fourteen lines to tell, for instance, that he does not like the weather when it is cold—or hot. We repeat, with time and patience anybody can do it; thousands and thousands have succeeded. But when it comes to setting forth in fourteen or twenty-eight lines either in prose or measure, so that the idea is not only correctly stated by the writer but may also be understood by the lay reader, the phase rule of Willard Gibbs, we confess that we have never heard of the genius who could do it.

Now some men are easy talkers with very little to say, while others who are among the greatest of men, would rather tackle an I. W. W. strike than make a speech. But we are not discussing oratory or talking for show. We are considering the need of clear, succinct definitions of conditions and processes that are needed in every control and every research laboratory, in every technical report and in giving commands as well as acknowledging them. There's a lot of psychology inside of most men's heads, just a little further in than their ears, and the reactions take place according to the language used.

The use of language, of our own language, is an art, a subtle but very important art that is in daily use; and it is far more needed in business than it is in idleness. Mastery of it is attained by the cultivation of a taste for it. The boy who does not try for this thing before he undertakes the more detailed preparation for his career is an ass. He will not gain it by reading stuff written to sell to those who lack it, and unless he has the industry to acquire it in the days of his youth he will sidestep along through life, always ashamed and always embarrassed by the need of it.

Decadence of the Iron Casting

It is not chance, but the orderly development of industry that has caused the iron casting to occupy a smaller and smaller place in what is broadly known as "the iron industry." The chief factor in the development has not been strength or safety, as might have been supposed. In 1899, before a meeting of one of the foundrymen's associations, a mechanical engineer of some note, lately returned from abroad, observed that he was not particularly interested in their discussions of iron foundry practice, because he had become convinced that the future of the industry lay in the steel casting. Events have proved that he was wrong. While the production of pig iron has increased three-fold since 1899, the tonnage of steel castings produced bears a relation of only 3½ per cent to the tonnage of pig iron. If safety and unit strength were the important factors the steel casting industry would have expanded much more rapidly. If it is a case of the total strength of the member the iron casting has much to commend it, for on account of size in proportion to value per pound one obtains a large radius of gyration at a low cost per pound, the iron casting being cheap for its strength even if only the outer portions are stressed.

There are no statistics of the production of iron castings, but the production of pig iron in grades used by the gray iron and malleable iron foundries furnishes an index. The statistics of pig iron production, segregated by grades, were first gathered for the year 1900. Then we have it that in 1916 17 per cent of the pig iron went to iron foundries, against 23 1/3 per cent ten years earlier and 31 per cent 16 years earlier. The figures are conclusive even though not entirely accurate as a measure of the production of iron castings. The proportions of scrap melted may have changed, but the probability is that the proportion of scrap to pig iron decreased, as the open-hearth furnace has in recent years bid favorable prices for scrap.

It is a change in manufacturing methods that has been chiefly instrumental in relegating the iron casting more and more to the background, in a sense, the greater and greater standardization. While the molding machine represented a great step it cannot compete with the press and other instrumentalities for working rolled steel into finished wares. We make things more and more to one pattern. From locks, bolts and hinges up to the heaviest articles we find rolled steel supplanting the iron casting, and indeed when we look about us to see what the largest castings are used for we find a great many of them in machinery for making or fabricating steel! In those cases the iron casting is merely digging its grave.

It has been impossible for the cost of converting pig iron into the finished casting to be decreased as greatly as the cost of converting pig iron into finished steel products because the margin was not sufficiently large at the outset. The manufacture of steel pipe, for instance, has been very greatly improved whereby when prices are low steel pipe sells for only about twice as much as cast iron pipe. Accordingly, the production of welded iron and steel pipe and tubes in 1916 was two and one-half times as large as the production of casting iron pipe and fittings, although that is one of the large items in the iron casting group.

The specialization that has fostered the use of rolled steel has not been confined, of course, to the industries that work up the steel, but has permeated its manufacture as well, whereby the old-fashioned general purpose mill has largely disappeared, to be replaced by mills that are highly specialized, continuous, tandem and otherwise. When the demand for a given form of rolled steel has doubled it has been possible to devise means for making it more economically, while that has not been the case in similar measure with the iron casting industry.

Chemists in the Making

To the Editor of Metallurgical & Chemical Engineering

SIR:—An anonymous writer, whose name is not hard to guess, has been telling his fellow members of the Chicago section of the American Chemical Society, his early experiences in the practice of chemistry; setting forth his reminiscences in several issues of their monthly bulletin. He admits that he is now prosperous, but prosperity was slow in coming to him. We shall describe one of his adventures because it throws light upon some modern promotions of chemical enterprises that have come under our observation, undertaken in a similar manner.

This particular chemist had been analyzing ores in the Pittsburgh region but bad times came along and the furnaces closed down. In answer to an advertisement he accepted an offer to become the "chief chemist" of the R—— Chemical Company of Chicago, at a modest salary. Mr. R——, the founder had been reading chemical books and had discovered nothing less than wonders. It was too easy! Here were chemists, pining and sighing away for a method to fix nitrogen from the air, and there were the directions, plain as your hand before your face, all printed out in the chemistry books. It merely confirmed him in the opinion that of all blind mortals those scientific theorists were the blindest.

His epoch-making discovery consisted in this: he gathered from his reading that nitric acid was a regular old crackerjack of a solvent; that it would eat into almost anything. He made careful notes of some of the things it would dissolve and of some that it wouldn't. He also read that when an electric spark is passed through air, a certain amount of nitrogen is oxidized to nitric oxide and that with this, nothing but more air and water is needed to have it turn into nitric acid, all of itself. Then he bethought himself of the poor gold miners who dug up vast quantities of earth and rock to produce very little gold. He looked up his notes and found that nitric acid would dissolve nearly everything, as far as he could figure it, that was in the ore except the quartz and the gold. Then he proceeded to design and patent a nitric acid machine that produced a lot of sparks and had a container attached to catch the nitric acid as fast as it was made. The rest was easy. All the miners had to do was to whirl in and buy one or more of his nitric acid machines, set them up and, by making all the nitric acid they wanted, concentrate their ores right down to gold nuggets and quartz, on the spot. Nothing like it had been thought of in the way of concentrating ores before or since—in the history of man, let us add, to give the promotion twist to our language. He disclosed his secret to a friend who had done well as salesman for a wholesale grocery house and the friend threw up his job, mortgaged his house for $10,000, and came in as a partner on the ground floor. Then the company was organized, offices were taken, a campaign of advertising begun, a shop was opened up, mechanics were set to work and a draughtsman with an engineering past but too fond of drink to be steady was engaged. Orders came in and the prospects were hopeful, although the bank account was getting low and it seemed advisable to have a chemist at hand for talking purposes as the first of the apparatus drew near completion.

At this point the chemist from Pittsburgh entered and he found that not a single feature of the whole layout had been tested. He induced the draughtsman to sober up because he had a rare sense of mechanics, and the best thing the new chemist and the sobered-up draughtsman could do was to work out a plan of research that, hurry as they might, would take at least two years to reach results. They reasoned that the various effects of temperatures, pressures and other factors would have to be determined and plotted before an apparatus could be designed, and concluded that even if they made a lucky strike they would need to know under what physical and chemical conditions they obtained it. They were working in utter darkness and they urged that, before the money was all spent, they make at least a few tests.

To Mr. R—— this was twaddle, piffle, rank theory and useless and undesirable experimenting. He pointed out on page 701 of Richter's Inorganic Chemistry how part No. 1 of the apparatus was bound to succeed and on page 357 of Muspratt he demonstrated how part No. 2 could not fail. He was so certain of results that he did not even care to be present at the first trial. If his chemist and draughtsman would only do as he told them and go ahead and construct the apparatus, there would be less trouble—and less talk. The partner with the mortgage on his house stuck to his job at the office and continued to make sales for later delivery. In time the apparatus was built as designed and all the parts were connected and set in motion. After operating at capacity for two hours, delicate reagents indicated slight traces of nitric acid. It was hardly to be smelled but the slight traces—albeit no more—were proven to be there. That was the capacity of the apparatus. The chemistry books were right but the trouble was that Mr. R—— did not speak the language. He was sent for and when he arrived, according to the author, he "swore like a Turk at Muspratt and Richter—and then took everybody out for a drink."

That was the end of the R—— Chemical Company and the chemist labored long at many a task within and without his profession before he struck his gait. The type of practical men who will not submit their theories to the test is far from extinct. Many of them are still abroad in the land. It would be a dreadful insult to call them theorists; they would deny it with warmth and vigor. The term theorist is an expression of opprobrium that seldom has a definite meaning and is a word often applied by the ignorant to those who believe in looking things up before they go ahead. It would make this issue unmailable to print the practical man's usual synonym for "theorist."

E. H.

Buffalo Meeting of theAmerican Institute of Chemical Engineers

The ninth semi-annual meeting of the American Institute of Chemical Engineers was held in Buffalo from Wednesday, June 20, to Friday, June 22, inclusive, with headquarters at the Hotel Statler. It was an excellent meeting, and a most enjoyable and profitable one. The attendance was exceptionally good in spite of the urgent requirements on the members' time at present, and the members showed by their attendance, and by the discussions, that scientific meetings are extremely valuable in the present crisis, and that there are more reasons for holding them now than ever in order to co-operate with each other and with the Government to the fullest extent.

Wednesday Sessions

The meeting was called to order on Wednesday morning in the Hotel Statler by F. A. Lidbury, chairman of the local committee on arrangements, who introduced David C. Howard, first vice-president of the Buffalo Chamber of Commerce. Mr. Howard welcomed the Institute to Buffalo and outlined the wonderful industrial growth of the city which he had been in close touch with. He made a special plea for the Institute to exert its influence to obtain the right to divert more water for power purposes on the American side of Niagara Falls, on account of the great shortage of power there.

President G. W. Thompson responded on behalf of the Institute and then opened the business meeting.

The secretary, J. C. Olsen, read the report of the Council, which contained some interesting announcements. In the Council meetings co-operation with the Government had been discussed. Applications had been received for the affiliation of student societies, but it was not thought advisable to do this at present as many of the professors in charge of the societies are not in active chemical engineering work. The feasibility of establishing associate membership was also discussed, but no definite action was taken. The Council decided to recommend the appointment of a committee to consider the further adoption of the metric system. It also authorized the treasurer to invest $500 in Liberty Bonds. It was not considered necessary to take a census of all the members and their specialties, as it was thought that the Bureau of Mines census covered this.

In connection with the action of the Council on the metric system, the secretary, J. C. Olsen, announced that the Institute had sent out literature to its members of both the American Institute of Weights and Measures (opposing the metric system) and the American Metric Association. He also read a letter from Dr. Baekeland expressing surprise that the Institute had sent out circulars against the metric system, and urging the use of this system. Dr. Palmer moved that

PHOTOGRAPH TAKEN AT BUFFALO MEETING OF AMERICAN INSTITUTE OF CHEMICAL ENGINEERS

a committee be appointed to carry out the Council's recommendations. Mr. Lidbury said that the metric system should be considered by the Institute from the standpoint of the chemical engineer and not from the standpoint of the public. Professor Withrow did not think it advisable to urge the adoption of the system unless the individual membership was circularized to find out whether any would be seriously affected. Mr. Lidbury replied that it was not the intention to urge the adoption in any particular industry, but simply to go on record as favoring the system. After the discussion the motion was passed to appoint a committee.

The secretary in his report stated that the membership consisted at present of 229 regular, forty junior and one honorary member.

The report of the Committee on Engineering Education was read by Professor Withrow. He did not think that the committee could do much during the war, as many of the professors have their time taken up by the Government and by the industries. Professor Withrow made a strong plea for the continuation of all chemical education on an even stronger scale than ever during the war. He said that the Society for the Promotion of Engineering Education would meet with the Council of National Defense in Washington instead of at Northwestern University as originally planned. Means will be discussed for changing the curricula to meet war demands. The committee recommended that the Institute ask all teachers to instruct chemical engineers in the fundamentals of topography, military engineering and explosives. In the discussion on this recommendation it was suggested that the chemical engineers were so small in number that it was not advisable to teach them military engineering.

After considerable discussion on the question of keeping chemists in the industries and in their proper places, the president appointed a committee to report Friday morning, after having drawn up resolutions on this question to send to the proper authorities.

The president announced that invitations had been received from Chicago, St. Louis and Columbus, Ohio, for holding the winter convention.

MANUFACTURE OF GLUE

The first paper was presented by **A. Lowenstein** of Chicago, Ill., on "Some Machinery Employed in the Manufacture of Glue." The author stated that most of the distinctive improvements in glue manufacture had taken place in the chilling, cutting and spreading of the glue, and he confined himself to a discussion of these subjects. Glue manufacturers have been very conservative in adopting new equipment.

The old method of handling glue consists in running the concentrated solution from the evaporator into wood or galvanized-iron pans and chilling them by running water or in a refrigerating room. The cakes formed are then cut with wires or knives into blocks or sheets. They are then spread on nets.

The old methods of chilling and cutting glue require considerable space for cooling room, the pans often rust and leak, "tops" and "bottoms" are formed, and in warm weather difficulty is experienced with liquefying organisms. The author mentioned a chilling wheel used successfully at present by one of the large companies, and having brine circulated in the rim. This wheel is understood to spread a sheet 30 in. wide.

He also described the continuous method of chilling, cutting and spreading patented by Maurice Kind (1,046,307), and the machine used in this method. It consists in running the glue or gelatine from the evaporation into a head tank over a continuous belt, subjecting it to chilled air and cutting the semi-solid strips into sheets. This machine is used by a large number of glue manufacturers. It requires a space of 85 ft. by 10 ft., uses 10 hp. and 10 to 12 tons of refrigeration. The capacity is 4300 lb. of dry glue per twenty-four hours, based on spreading ¼-in. sheets and a feed containing 16 per cent solids.

In discussing the problem of drying the author stated that it is still generally done in straight tunnels with longitudinal circulation of warm air. Vacuum driers have not been very successful.

In the discussion it was asked whether any attempt had been made to use moist air in drying glue. Mr. Lowenstein replied, that to his knowledge, no deliberate attempt had been made to use moist air as it is desirable to form a skin on the surface of the glue. For this purpose dry air has always been used.

TREATMENT OF SEWAGE BY AERATION

In papers read at previous meetings the author, Prof. Edward Bartow, described experimental work with activated sludge carried out in the sewage experimental station of the Illinois State Water Survey and the University of Illinois (see *Met. & Chem. Eng.*, Vol. XIII, page 901 (1915). The removal of ammonia and the development of nitrate nitrogen were also described, and it was shown that the sludge was valuable as a fertilizer. The present paper describes further work carried out at the above mentioned sewage experimental station.

A continuous-flow plant to work on the activated sludge process and which was expected to handle 200,000 gal. of sewage and sludge per day was put in operation May 25, 1916. It was shut down June 11, 1916, to repair leaks in the concrete work. The plant was again operated from July 11 to Oct. 22, 1916, the amount of sewage added varying from 61,000 to 177,600 gal. per day. About 2 cu. ft. of air per gallon of sewage was required to obtain stable effluents.

The plant contains a screen chamber and pumping pit, a grit chamber, an aerating chamber, a settling chamber, a blower room and a laboratory equipped with sludge-drying apparatus. There is also a sludge-drying bed and a pond into which the effluent from the process may be discharged. The sewage is drawn from the main sewer of the city of Champaign.

The plant was again started Jan. 17, 1917, after cutting out the grit chamber and substituting a short box into which the sewage is pumped. It has operated continuously till the present time.

A number of experiments were carried out on different methods of air diffusion. The results of these comparative tests indicate the superiority of Filtros plates as air diffusers over perforated pipes such as used in the tests. The wooden blocks were hard to handle, partly on account of the design of the containers. They showed signs of deterioration even in the short time used. No difference could be distinguished between coarse and fine grades of Filtros plates.

It is necessary to have a practical and economical method of drying the sludge. Sand beds have not proven

successful. The sludge contains 98-99 per cent of moisture. In experiments so far filter presses have not given good results. A rotary filter containing Filtros plates was also tried, but did not give satisfactory results. A modified 8-in. basket-type centrifuge and a modified cream separator were tried. The holes of the centrifuge were covered with a strip of rubber packing. The best results with this machine were obtained at a speed of 1500 r.p.m., which was the limiting speed.

Sludge cake containing from 85 to 86 per cent of moisture was obtained by the cream separator in six to eight minutes, which showed the desirability of making further experiments. A specially designed centrifuge was obtained from the Tolhurst Machine Works of Troy, N. Y. The machine was 1 ft. in diameter, 9½ in. high, and at 1800 r.p.m. exerted a centrifugal force of 550 lb. Sludge cake containing 88 per cent moisture was made with this machine. A 40-in. machine would deliver, on the basis of the experiments with the smaller machine, about 9340 lb. of sludge containing 88 per cent moisture, or about 1100 lb. of dry material. On the supposition that ½ ton of dry material is obtained from 1,000,000 gal. of sewage, one 40-in. machine would dewater 1,000,000 gal. per day. The machine appears practical to prepare the sludge for a dryer.

In the discussion which followed Dr. Wm. P. Mason asked what the nature of the effluent was. The author replied that it usually had a turbidity of less than 5 parts per million and was practically water white. The activated sludge method has been used on stock yards waste, requiring 4 cu. ft. of air per gallon of sewage and an aeration period of eight hours. He said it takes ten days to get a new plant running well. Dr. Olsen asked what proportion of the nitrogen in the sewage was obtained in the sludge. Professor Bartow had no figures on this but thought that all the nitrogen in the sludge came from the solid material which was in the sewage.

INTENSIVE CHEMICAL PREPARATION

A paper was then read on "Intensive Chemical Preparation" by Dr. **Chas. S. Palmer** of the Mellon Institute, Pittsburgh, Pa. He spoke especially on the desirability of giving high and preparatory school students three years of preparation in chemistry, including inorganic and organic chemistry, qualitative and some quantitative analysis. He thought it would be of enormous benefit to the student in connection with his subsequent college training.

Dr. Olsen in discussing the paper said the argument was excellent for young men and women who never go to college. The average business man, banker, etc., could more intelligently support chemical and allied industries if he knew more chemistry. He thought chemistry should be made a compulsory subject in the New York City High Schools. But he said that in his experience better progress was made in chemistry in college by those students who had no chemistry in high school as the chemistry was usually improperly taught. He said the need was for not only more chemistry in the high schools but for better chemistry. The paper was discussed by several others with experience along these lines and it was the general opinion that the standard of teaching chemistry in high schools could stand considerable elevation, as in many instances the chemistry teachers were overburdened with other work.

WEDNESDAY EXCURSIONS

After luncheon at the hotel an automobile trip was taken by the members and ladies around the city through the residential sections and parks and then to the Buffalo Foundry & Machine Company's plant in the outskirts of the city. A tour had been arranged by the courtesy of the latter company which proved very interesting to the members. Booklets describing the plant and laboratories were distributed, which greatly facilitated the inspection. Each machine or piece of apparatus in the foundry and machine shop was numbered and corresponding numbers in the booklet explained each one. The company is building a large new research laboratory which will house all of the chemical, physical and semi-commercial testing laboratories. Large machining operations were first viewed, together with several large finished castings of dryers, nitrators, caustic pots, etc.

From the machine shop the party went to the plate shelf shop where welding and riveting operations were inspected. The foundry was next visited where the large castings were being poured and then a trip was made to the demonstration plant, where various small size dryers were in operation.

MANUFACTURE OF LINSEED OIL

This paper, which was read by **Glenn H. Pickard,** consulting engineer of Chicago, Ill., will be found in full on pages 12 to 16 of this issue.

In discussing this paper Dr. Wesson said the same problems were encountered in the manufacture of cottonseed oil. The chief improvements had been made in methods of cooking the seed. Dr. Thompson said the oil in the linseed cake was very different in amount in different spots and that it would be better to have the cake of even thickness.

TRADE WASTES DISPOSAL

The paper by **Harrison P. Eddy,** of Metcalf and Eddy, Boston, Mass., is published in full on pages 32 to 36 of this issue.

In the discussion Dr. Mason asked if anything had been done on the red liquor from sulphite pulp mills. Mr. Eddy had no data on this. Dr. S. P. Sadtler spoke of work being done on sterilization of tannery waste. Mr. J. V. N. Dorr spoke of a plant in Pennsylvania which had experimented with sedimentation by continuous settling. The results indicate that an overflow is obtained which complies with the law. Two 100-ft. circles are needed to take the complete output of the plant which is considered a large one. The solid material is incinerated. Professor Withrow mentioned a wood distillation plant which the authorities said was contaminating the water. They found that when the chlorine was stopped the creosote taste stopped which existed under chlorine treatment. Mr. Eddy said that no doubt under certain conditions a taste was encountered but it was less liable to be noticed when organic matter was present. This subject was also discussed by Messrs. Bartow, Mason, Snowden and Frerichs. It was brought out that hypochlorite did not produce any taste whereas chlorine did.

Thursday Sessions

The Institute was entertained all day Thursday at the Buffalo Canoe Club, near Crystal Beach, Ontario.

A steamer was taken at 10 a. m. to Crystal Beach and a launch from there to the Canoe Club. Several of the members walked along the beach to the clubhouse instead of taking the launch. The clubhouse is beautifully situated in Abino Bay, having a natural shelter from the heavy storms which are frequent on Lake Erie. The club has a private pier with two-story pavilion. The canoes are kept on the first floor, and the second floor, which is used for dancing, was given over for the holding of technical sessions. Upon arrival at the club a technical session was held in this pavilion.

SULPHURIC ACID

The session consisted of papers by Professor **James R. Withrow** of Ohio State University on the elevation and conservation of sulphuric acid and in discussion of these subjects.

Professor Withrow presented the results of some work which he had done on the elevation of sulphuric acid with waste steam, the object being to do away with air compressors. One of the methods mentioned consisted in simply substituting the steam for air in an acid egg. He said the absorption by the acid would be inappreciable in the short time during which the steam acted on the acid. Another method was to have three eggs, one for acid, one an intermediate air cushion and the third steam. In this manner no steam would come into contact with the acid. Another method was to use the waste steam to run acid pumps instead of electricity, or to have both available. Still another method was to have a sloping helical screw arrangement by which a steady stream of acid would be delivered. Steel pressure tanks can also be used in place of earthenware eggs.

Professor Withrow also spoke of the necessity of conserving our sulphuric acid to the greatest extent, as enormous quantities are needed for explosives and fertilizers and many manufacturers allow acid to go to waste because they have no concentrating system. He thought it wise to concentrate waste acid even if the operation only paid expenses, as it would furnish additional acid for fertilizers and explosives. Imports of pyrites and sulphur are not normal and the conservation of sulphuric acid is a vital necessity.

In discussing Professor Withrow's talk, Dr. Ludwig A. Thiele of Columbus, Ohio, said that elevation by steam was all right in concentration but that in the chamber process it was hard to find anything better than the acid egg. He had tried pumps of all kinds and found the greatest trouble to be with the packing. Braided lead is about the only material which will work.

Mr. Hugh K. Moore of the Berlin Mills, Berlin, N. H., asked whether anyone had ever tried making a cathode of the material used in the elevating machinery and passing a current to prevent corrosion. He had tried out a similar scheme successfully.

Mr. Arthur B. Conner of Detroit, Mich., said he thought the use of waste steam very practicable and did not see any reason why it could not be used.

In discussing ammonium sulphate for which sulphuric acid is used, Mr. Palmer said that in Germany, he understood, they were making ammonium carbonate from ammonia obtained by the Haber process, mixing this with gypsum and making ammonium sulphate. The calcium carbonate is used again to make ammonium carbonate.

Mr. Thiele said that several plants in Germany were using a mixture of calcium sulphate (gypsum), nitre cake, quartz sand and sodium sulphate for producing glass and oleum. He said 50,000 tons was being produced in this way and that it presents great possibilities. The mixture is heated in an electric furnace at 850-900 deg. C. Mr. Thiele thought that steam would have a bad effect due to heating in acid chambers. He mentioned a valveless centrifugal pump which gives good results.

Dr. Palmer said he had been recently informed that the Haber process was being used on a very large scale in subterranean passages in Germany. No one is allowed to go near the apparatus. Mr. Frerichs said he had understood that hydrogen and nitrogen were too expensive to use the Haber process and it had been kept going before the war by Reichstag appropriations. The cyanamid process was probably better. Germany uses the latter process on a large scale.

This brought up the question of power costs and Mr. Moore said that by using a steam turbine as a reducing valve with steam at 5 lbs. pressure power could be generated for $7.50 per hp. year. With steam at 250 lbs. pressure, the cost would be about $16 per hp. year.

Mr. Frerichs mentioned the Alabama River project, for which $9,000,000 had been appropriated by the Government to make the stream navigable. If $6,000,000 were added to it water can be diverted for power purposes. The Cyanamid Company offered to pay the interest on the money for being allowed to use the power. They figure $3 per hp. year as the cost. Mr. Thiele mentioned a great new power plant near Wheeling, W. Va., in the Fairmont region, where power can be generated very cheaply. It consists of a great by-product coke plant fed by gravity from the coal mines, the coal costing $1.20 per ton.

Thursday afternoon was spent in sailing, canoeing and walking. It was a most delightful day with what they call a "lady's breeze" and the afternoon was greatly enjoyed. Dinner was served in the clubhouse at 6.30 p. m. Following the dinner a technical session was held on the pier. This session had originally been planned for Friday evening but was transferred to Thursday evening and the banquet held Friday evening.

RENOVATING A SULPHIDE MILL

The author of this paper, **Dr. Hugh K. Moore** of the Berlin Mills, Berlin, N. H., presented a very interesting detailed description of work which he and his assistants had done at LaTuque, P. Q., Canada. The work was done in connection with renovating and reconstructing a pulp mill running on the so-called sulphate process. The paper was a splendid example of what chemical engineering can do and publication of this paper in full is reserved for a later issue.

In the discussion Doctor Palmer asked what the cost of coal was at that point. Mr. Moore replied that it was approximately $5 per ton. Mr. Harry O. Chute mentioned a multiple effect evaporator used in evaporating brine. Deposits collected on the tube which he thought consisted of magnesium sulphate.

He thought the acetylene method of removing this mentioned by Mr. Moore would have saved considerable money.

Owing to the lateness of the hour and to the necessity of taking the boat back to Buffalo it was decided to

postpone the reading of Mr. H. D. Baylor's paper on waste heat utilization until Friday morning.

The party returned to Buffalo on the 9 p. m. boat, arriving in Buffalo about 10.30.

Friday Sessions

The meeting was called to order Friday morning by President Thompson, who asked for a report of the committee appointed on Wednesday to draft resolutions urging the government to keep chemists and chemical engineers in their proper spheres. Professor Withrow read the resolutions which had been drafted. The substance of the resolutions was as mentioned that the American Institute of Chemical Engineers urges the exemption of chemists and chemical engineers unless their chemical ability is needed. The resolutions were unanimously adopted.

It was decided to send a telegram to President Wilson and other authorities if advisable, stating that the resolutions had been passed and explaining the reasons.

WASTE HEAT FROM CEMENT MILLS

A paper by **H. D. Baylor** of Sellersburg, Ind., was read by title as the author was unable to be present. The paper discussed the use of waste heat boilers with cement kilns at the Louisville Cement Co., Speeds, Ind. The gains realized were as follows:

(*a*) The decrease in fuel required to burn a barrel of cement from approximately 110 lb. per barrel to less than 100 lb., this being largely due to the preheating of the air for combustion by drawing it over the hot clinker and also in having the coal feed under absolute control.

(*b*) An increase of general efficiency of heat absorption from 37.6 per cent to 67.2 per cent of total heat supplied to kilns, the gain being shown in the boiler horsepower developed without an increase in fuel consumed in kilns per barrel.

(*c*) The recovery of at least one half the dust that was formerly carried out the kiln stack.

(*d*) And last but not least, the solution of draft control on the kilns through the use of the large induced-draft fan. This alone is quite worth while, since cement engineers seldom agree as to size and shape of kiln stacks; but with the variable fan speed obtainable each authority can have just the draft that best suits his conditions.

In discussing the paper President Thompson mentioned a smelter having fourteen reverberating furnaces, each one connected to a boiler, the boilers being connected to a common header. These boilers furnish power to run all the fans and one handling machinery. Dr. Moore said that the radiant heat furnishes a great deal of the heat furnished to waste heat boilers. Mr. Meade said that the problem was an old one but that recent success was due to the higher velocity of the gases.

POTASH RECOVERY FROM FELDSPAR

A paper on a new method of potash recovery from feldspar by Prof. **J. P. W. Frazer** and Dr. **E. Miller** of Johns Hopkins University, Baltimore, Md., was read by Dr. Miller. The paper described the results of experiments made last year in the production of potash and aluminum. Feldspar is treated with alkali forming a compound analagous to leucite, which can be leached. The feldspar is ground and mixed with 8/10 of 1 per cent by weight of potassium hydroxide. The hydroxide is used as a solution. The mixture is then evaporated to dryness and then heated to 200 to 300 deg. C. The leucite product is insoluble in water, hence the product is then leached, dissolving out the alkali. This solution is regenerated by treating with lime. The artificial leucite contains all the potash, the treatment simply taking out one molecule of silica. This artificial leucite is then treated with acid, any mineral acid sufficing. Methyl orange is used as an indicator. If hydrochloric acid is used an amount is taken equivalent to the potassium in the leucite. The end product from this leaching is analogous to kaolinite. This is treated with sulphuric acid and aluminum sulphate is obtained. The authors claim that the yield of potassium chloride is theoretical and that the yield of aluminum is about 86 per cent. A feldspar containing 10 per cent potash will yield ¼ ton of 80-per cent potassium chloride to one ton of aluminium sulphate.

THE AMERICAN POTASH INDUSTRY

A paper on the possibilities of developing an American potash industry was read by **Richard K. Meade** of Baltimore, Md. Publication of this paper in full is reserved for a later issue.

POTASH FROM BEET SUGAR FACTORIES

Mr. **H. E. Zitkowski** presented a paper on potash from waste liquors of beet sugar factories which will be found published in full on pages 17 to 19.

In the discussion on the potash symposium Mr. H. K. Moore said that evaporation was important in some processes. He thought that it did not pay to have more than four effects. By putting the liquor in the last effect and working backwards better results are attained. He is at present designing a 10-effect evaporator for concentrating digester liquor. He thinks that in the beet sugar industry backward evaporation would solve the problem as high final heat does no harm.

Mr. Thiele said that more time should be spent in exploring the country for potash deposits. The subject was also discussed by Messrs. Meade, Toch and Chute.

FRIDAY EXCURSIONS

On Friday afternoon the members and ladies were taken in automobiles to Niagara Falls. A stop was made on the outskirts of Buffalo at the Curtiss aeroplane sheds and a flight was witnessed. A special trolley car was provided in Buffalo to take the party around the gorge route. This car was furnished by the courtesy of the Buffalo Foundry & Machine Company. After the trip was over the party went to Goat Island and refreshments were served. The party returned to Buffalo about 7.30 p. m., the banquet starting about 8 p. m. The banquet was very well attended and excellent speeches were made. It was a fitting ending to a most successful meeting. President Thompson acted as toastmaster. F. A. Lidbury spoke of the chemists' obligations in the war and of several things that are being done. Prof. Alfred W. Smith of Case School of Applied Science, Cleveland, Ohio, spoke of the relation of education to the war. Prof. W. P. Mason gave an amusing talk on "temperance" and told several funny stories. Maximillian Toch gave a very interesting talk on the

various activities in which chemists are taking part during the war.

Great credit is due the local committee for the splendid entertainment features. F. A. Lidbury was chairman, David Bell had charge of the autos. David C. Howard was vice-chairman and Benj. H. Bonnar was responsible for the splendid Canoe Club outing Thursday. Other local committee members were W. M. Corse, C. M. De Forrest, Henry Russell, W. H. Watkins, and John Younger.

Coming Meetings and Events

American Chemical Society, Boston, Sept. 10-15, 1917.

Third National Exposition of Chemical Industries, Grand Central Palace, New York, week of Sept. 24, 1917.

American Institute of Metals and Foundrymen's Association, Boston, week of Sept. 24, 1917.

American Electrochemical Society, autumn meeting, Pittsburgh, Oct. 3-6, 1917.

American Institute of Mining Engineers, annual meeting, St. Louis, Oct. 8-13, 1917.

Scientific Meetings in War Times

A number of our scientific societies have deemed it advisable "on account of the war" to either cancel or postpone their future meetings and conventions. The American Electrochemical Society disapproves of this action and at its recent board meeting adopted resolutions encouraging the holding of meetings.

Modern warfare is not so much a matter of prowess at arms as it is a stupendous engineering undertaking. To hasten this war to an early and victorious close our many thousand engineers must bring to bear every possible effort. However, individual, independent effort is not desirable at this time: *concertive* action is absolutely essential for the most efficient service.

In order to expedite the solution of many of the new problems that have arisen as a direct consequence of our martial state, unrestricted discussion of the problems (with but few exceptions) at scientific meetings is bound to give all of us a clearer understanding of the real points at issue, of the urgent needs of our country at this momentous hour.

Meetings of scientific and technical societies have ever served as a great stimulus for their members and have been a "clearing house" for many of the best thoughts and ideas of our professional men.

Let us follow the good example set us by England. Let us encourage rather than discourage the holding of scientific meetings in these war times. When England found herself confronted with a very serious shortage of sulphuric acid, glass, dyes, electrodes, brass, furnaces, etc., the scientific societies arranged symposiums on these subjects and invited not only all of the members to attend but further, urged those factory men who were not members to come to the meetings to give their views and experiences and to learn all they could in return.

Just as a large business corporation depends upon the organized effort and efficiency of the several units and departments, so does our government, now more than ever, look to the organized concertive effort of its large engineering bodies for quick and efficient results. Let us continue holding our meetings and hold them more frequently than ever before.

Colin G. Fink.

Granular Carbon Electric Furnace

By Samuel A. Tucker

A very useful furnace for maintaining temperatures considerably above those possible with the usual wire-wound furnace has been constructed in our laboratories.

There is a furnace on the market which operates with a granular carbon resistor, but the refractory parts are complicated and it is sold at such a high price that it is less useful than such a piece of apparatus should be.

The design here shown in Figs. 1 and 2 is simple to construct, the parts are inexpensive, it will reach a high temperature in a short time, energy consumption is not great, and the heated space is perhaps larger than is usually found in such furnaces. One difficulty in using a circular granular carbon resistor is in the tendency to uneven heating, particularly at the start. This furnace is therefore provided with four electrodes, as shown in the sketch.

The furnace body, 12 in. x 12 in. x 9 in., is of fireclay, with opening as shown. This particular shape was used because it happened to be in the laboratory; however, such a body could have been taken from one of the usual gas crucible furnace parts which are to be obtained on the market. Four holes are bored to admit the elec-

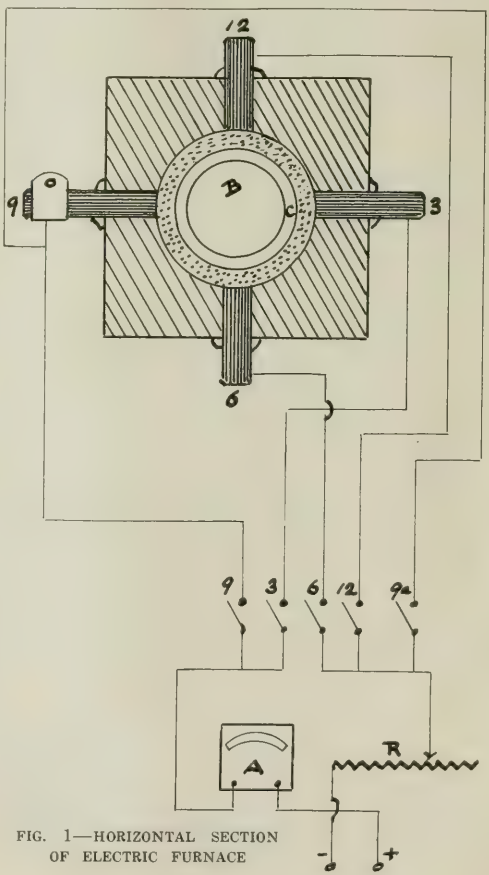

FIG. 1—HORIZONTAL SECTION OF ELECTRIC FURNACE

trodes about 1 in. diameter to the open space *B;* this space is partitioned by the carborundum ring *C,* which is 4 in. outside diameter, 3 5/16 in. inside and 3¼ in. high. This gives an annular space for the granular carbon connecting all four electrodes.

Granular carbon was obtained from the National Carbon Company, the size of grain being about 20 mesh, and was filled in to the top of the refractory ring.

The ring itself was constructed as follows (Fig. 3): Carborundum ground fine in a ball mill was mixed with

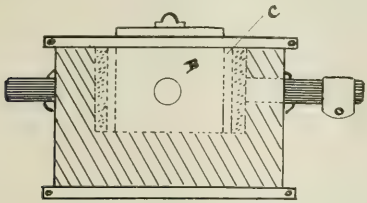

FIG. 2—VERTICAL SECTION OF ELECTRIC FURNACE

25 per cent fireclay and enough water added to make a thick mass. This mix was then tamped in to the cardboard mold shown in the drawing. The inner form at 1 and 2 is made by wrapping the cardboard on wood form 2 and holding it on the wood with small tacks or glue.

The outer form at 3 is also of cardboard held on the wood base projecting up inside the cardboard cylinder, as shown by the dotted line, and strengthened by the wood block at the top. In this way the form can be made quite strong enough and at the same time is sufficiently porous to permit of the drying out of the mixture. After thoroughly drying in a gas oven at 110 deg. C., it is transferred to a gas muffle and thoroughly baked at a temperature of 900 deg.-1000 deg. C. The mold is of course lost, but it is so easily made that it is of little consequence. The ring so constructed is quite strong enough for the purpose intended, and furnace cover, etc., may be made in the same way. Electrical connections are made as shown in the diagram from the five switches with wire of about 50-ampere carrying capacity. On closing switches 9, 3, 6 and 12 we have adjacent electrodes of opposite polarity and a short time will suffice to show whether the ring is heating evenly. Should this not be the case, and one quadrant appears to be too hot, this can be cut out by opening the switches for that position. When all have become evenly heated 9, 6 and 12 are opened and 3 and 9a closed, by which arrangement it acts as a two-pole furnace, which is the normal manner of running.

The following figures give a run with such a furnace using direct current at 120 volts through variable rheostats *R:*

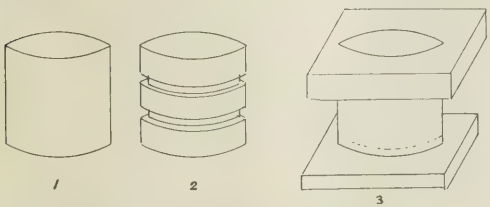

FIG. 3—CONSTRUCTION OF RING

Time	Amps.	Volts	Temp. Deg. C.	Remarks
9.30	25	..	..	1 pole
9.40	10	..	500 }	Changed poles
9.50	38	..	700 }	to regulate
10.00	12	..	720	2 pole
10.10	36	..	900	2 pole
10.20	18	98	1,000	2 pole
10.30	22	110	1,090	2 pole
10.40	23	98	1,200	2 pole
10.50	27	97	1,275	2 pole
11.00	24	98	1,300	2 pole
11.20	22	97	1,300	2 pole
12.00	22	97	1,300	2 pole

The furnace was covered with a carborundum disk and further with asbestos board with a small opening to allow the introduction of the thermocouple. In another case the furnace reached 1400 deg. C. in forty-five minutes using 50-60 amperes at from 51 to 53 volts.

It is necessary to have the electrodes fitted well to the openings provided in the body, and this can be done by wrapping with thin asbestos paper and luting with asbestos fireclay cement from the outside. Iron bands are necessary to clamp the body to prevent cracking.

The furnace described by A. W. Fahrenwald* is a very interesting design which has about the same purpose as this one. We have not had time to construct one of this type, but hope to do so in the near future, possibly changing the dimensions to permit of a larger working space and in this way can compare the advantages of each.

We believe that the refractory parts can be made for either type of furnace by the method here described, which would obviate the necessity of buying expensive alundum tubes, and it is possible that the carborundum parts would answer the purpose better than alundum.

Electrochemical Laboratory.
Columbia University.

American Society for Testing Materials

Annual Meeting at Atlantic City

The annual meeting of the American Society for Testing Materials opened on Tuesday, June 26, at the Hotel Traymore in Atlantic City. President A. A. Stevenson, vice-president of the Standard Steel Works, Philadelphia, Pa., presided.

On Tuesday morning the report of the executive committee was read. The membership is now 2167 as compared with 2071 last year. The translation of standard specifications into foreign languages has been delayed but the first ones are expected soon. Officers elected for the coming year are as follows: President Gen. W. H. Bixby, retired, Washington, D. C.; vice-president, Prof. Edward Orton, Ohio State University.

Tuesday evening was devoted to a reception and to the annual presidential address. Addresses were also made by all of the six past-presidents who, singularly, happened to be present. President Stevenson, in his address said: "The steel industry of the nation is drafting into its service all the newest inventions, labor-saving devices, intelligence and executive ability that can be employed in meeting the unprecedented call for steel products. Forty million tons were manufactured last year. That exceptional record will be exceeded this year, and extensions of plants are being hurried. The steel industry realizes the important part that it is to play in aiding the nation in winning the war. He outlined a plan for securing national standards through a committee made up of representatives of five national engineering societies.

The Manufacture of Linseed Oil*

By Glenn H. Pickard

Practically all of the flaxseed or linseed crushed in America is handled in the open-plate hydraulic press. Until recently a small proportion of the oil was won by the extraction of the seed with naphtha, but with the recent destruction by fire of the last plant operating on this principle, the process, so far as linseed oil is concerned, ceased to be in this country. The expeller is employed in a few mills, but the amount of oil produced by this means is a very small proportion of the whole.

CLEANING OF SEED

The first step in the manufacture of linseed oil from flaxseed is the cleaning of the raw material. The removal of the foreign matter in a consignment of seed is accomplished by specially designed flax screening machinery which employs the usual method of passing the grain over screens of proper sizes which separate, as completely as possible, the foreign matter from the flax seed. A current of air removes the chaff. This procedure will reduce the percentage of impurities to an amount lying between 1 and 2 per cent. The screenings are generally run through a separator, and the wheat, corn, oats and possibly other grains are sold as such, while the wild buckwheat, pigeon grass, wild mustard and other valuable weed seeds are sold to feed manufacturers.

The presence of oleagenous seed would deleteriously affect the quality of the linseed oil because the oils yielded by them are non-drying. The extent of the damage would naturally vary with the amount present. Non-oleagenous matter, particularly immature seeds and bits of the plants, impart a dark greenish color to the oil. The presence of much foreign matter will reduce the yield by absorption. It is economically possible to clean to such an extent that from but one to 2 per cent of impurities remain.

CRUSHING OF SEED

The cleaned seed is now crushed by passing it back and forth between rolls which are built in stacks of five. They are usually made of chilled steel and are 14 in. diameter by 48 in. long. The journal boxes are loose in vertical guides so that the weight of the other four is carried by the bottom roll. The seed passes between rolls four times and at each successive passage the pressure is increased by the weight of an additional one. The top, middle and bottom rolls are driven by power applied by rope or belt drive as the case may be.

The object of the crushing is to disintegrate the seed, thus breaking down the cell walls preparatory to expression of the oil. Consequently, subdivision to the greatest possible extent consistent with economy is the best practice. Generally all of the rolls travel at the same rate so that there is no grinding or mulling action to assist in the disruption of the seed itself.

Stacks of rolls have been built in which the speed of each varied, thus producing a grinding action by slippage at point of contact. No data are available to show whether or not an increase in yield resulted.

Given a standard set of rolls the two important variables are the revolutions per minute and the rate at which the seed is fed. Practice in both varies. Obviously the more rapid the rate in both instances the poorer the grinding will be. Observations have led to the conclusion that the crushing of about 10½ bushels per hour at a roll speed of 150 r.p.m. is the most economical practice on rolls 14 x 48 in.

TEMPERING OR HEATING OF LINSEED MEAL

In order that, when placed under pressure, the ground seed may more quickly, more easily and more completely give up the oil it contains, it is heated with or without the addition of moisture. This is accomplished in the heater or cooker, the unit of which is a cylindrical chamber with a steam jacket on the bottom and around the sides. These cookers vary in diameter from 42 to 84 in. Linseed oil mills are generally equipped with 72 or 84-in. cookers. The depth of the chamber is about 24 in. From two to four units, one above the other are generally used. In each receptacle there is a sweep which lies very close to the bottom in order that the meal may not lodge there and burn. The shaft to which these sweeps are attached is hollow. A finely perforated pipe is fastened to the back of the sweep and is connected to the opening in the shaft. Through this system steam may be admitted to the meal.

There are two practices followed, one in which the two-unit cooker is employed and steam is led into the meal in the upper chamber. The amount of steam varies with the moisture content of the seed. The feed is so regulated that the meal chambers are not full providing space above which allows evaporation to take place.

The other method is to use the "three" or "four" high kettle, adjust the feed so that the whole apparatus is full all of the time and admit no live steam at all except possibly when crushing old, dry seed which is hard to soften.

The factors entering into this operation are the speed of travel of the meal, and consequently time under heat, the temperature to which it is heated, and the amount of moisture present. If the time is too short the tissues are not thoroughly softened and the yield is low as a result.

When the temperature is low the yield falls and the cake is brittle and easily broken; if it be too high the cake has a characteristic and undesirable odor and the oil will be dark and in certain uses will cause trouble.

Too little moisture yields a crumbly non-adherent meal which will not pack well and from which the cake is unsatisfactory. If too wet the meal is soggy, the oil contains an excessive amount of moisture and the cake will be dark in color and tough.

We have, therefore, three factors to coordinate in the tempering or heating of linseed meal. The only means of control are the senses of the operator. He takes a handful of meal and compresses it. If it has a certain "feel" under pressure, packs in a definite manner, and oil can be started by the pressure of the hand, he says that it is well tempered. He modifies one or another of the elements of control, when the cake or the meal varies from his standard.

Obviously the personal equation causes marked fluctuation. No two men are in complete accord upon fundamental principles. No accurate data are available, if indeed any exist, on which to base a system. Little

*A paper read at the Buffalo meeting of the American Institute of Chemical Engineers, June 20, 1917.

is known of what really happens in the tempering operation. The theory is that the combined heat and moisture break down the walls of the oil cells, coagulate the albuminous sediment forming portions of the seed and reduce the viscosity of the oil, thus making it possible for the flow to be more quickly and easily accomplished under pressure.

Of the mechanism of the changes within the ground flax seed, or of the manner in which variations in operation bring about the results noted in practice, little or nothing is known. It does not appear to be a difficult matter to apply scientific methods of observation during the process with the view of securing means of definite and positive control so that variations in raw material may be made convergent in the meal cooker and so that uniform efficiency of extraction and uniform products may result.

THE FORMER

From the bottom of the lowest compartment of the heater the meal passes into a metal box mounted on a runway over which it travels to the "former," a machine which measures the amount of ground seed to constitute the charge for each of the plates of the press and compresses it to a soft cake. These formers are actuated by hydraulic, by steam or by belted power. The hydraulic type, the one commonly used, is operated from the low-pressure hydraulic system.

At the end of the runway on which travels the meal box is a hinged flapper frame on a table which moves at right angles to the travel of the box so that it may be pushed back under the stationary part of the machine. This consists of a head block of heavy cast iron supported by wrought iron pillars, designed to withstand the upward pressure of a base plate actuated from below by a hydraulic ram. During the operation a slide gate in the bottom of the cooker is opened by hand to allow the box to fill with meal. On the table is laid the press cloth in a strip about 15 in. wide and 6 ft. long.

The buggy box is now filled with meal and pulled out over the frame into which most of its contents fall. It is generally given two passages over the frame to insure an even filling of the space. Considerable skill is acquired by experience in the handling of the box in order to produce a clean uniform fill with the material evenly placed and of constant weight. The table is now pushed back under the head block, the power applied for an instant, then released, the table withdrawn and the flapper frame is lifted. The ends of the cloth are thrown over the top of the formed cake when the pressman slips a sheet of iron pan slightly larger than the frame and equipped with a handle on one end under the cloth and transfers the molded and wrapped cake to the press box. This type of former minimizes danger of injury to the operators because it is practically impossible to get one's fingers in a position where they will be crushed.

To do good work a former must mold a perfect and compact cake that will fit the press boxes, must work cleanly, that is, not spread the meal out to litter up the press room, must make a cake sufficiently coherent to permit of necessary handling without loss of portions of it and must deliver a cake of uniform density and thickness so that uneven pressure will not be caused in the press and uniform cakes will result after pressing.

There is a mechanically operated buggy box in which the box is on the end of a piston actuated by hydraulic power. The machine lacks the uniformity resulting from the effort of a man interested in doing good work because it will not run the meal box over the frame twice in order to have it evenly filled and thereby make a cake of uniform density. It doubtless, however, compares favorably with the work of green or indifferent operators. It does not make a reduction in labor expended because a man is required to operate this machine and to do the other work necessary to form and wrap the meal just as when all hand power is employed.

THE PRESS

The press used in the winning of linseed oil is the typical open-plate hydraulic machine, the essential parts of which are: The cylinder and lower block, frequently cast in one piece; a stationary head block which is bolted through to the lower block by means of heavy hammered iron columns; and the ram, on the end of which is placed a platen or heavy block rigid enough to prevent flexure at the ends so that even pressure will be exerted over the entire plate area.

Hydraulic pressure is obtained from power-driven pumps so equipped as to be capable of supplying both high and low pressures. One of the most popular forms of pump is a four-crank design furnishing both pressures. The hydraulic system consists of a supply tank for the liquid, which in this case is linseed oil, pumps, accumulators, valves, change cocks and piping. The accumulator is of heavy material superimposed upon a ram and guided in its vertical movement. Its object is to store hydraulic fluid which is intermittently used, thus producing more constant load on the pumps, to steady the pressure by reducing shocks which, if severe, would injure the machinery and piping, and to act as a regulating valve to maintain a uniform pressure. Both the high-and-low pressure systems have an accumulator. The low pressure is used to start the working stroke of the press and to operate the "former," the packer and possibly the other hydraulic machinery. It is usually set at 500 lb. per square inch. The high pressure varies between 3500 and 4500 lb.

The regulation of the presure is this: When there is no demand for fluid the plungers work idly by circulating the oil through and back to the supply tank by means of the automatic movement of a valve from a system of adjustable rods and levers at the accumulator. When working fluid is again required the by-pass valve is closed by the fall of the accumulator and the pump again delivers fluid at working pressure. When communication is opened to a press through an automatic change cock the pressure is turned onto the ram only from the low-pressure accumulator. The press ram travels up rapidly until a pressure of 200 to 300 lb. is reached, which is enough to start the oil. A choker in each pipe regulates the speed of the press by throttling the flow of the fluid. The ram travel is slowed down in proportion to the escape of the oil. When a pressure of 500 lb. is reached the oil from the high-pressure accumulator is automatically turned on to the press ram. The speed of travel is again governed by a choker so that the maximum pressure of about 4000 lb. is not reached until the ram is nearly at the end of its travel.

Press plates are at present generally made of rolled steel about ⅝ in. thick. They were formerly made of iron or of brass. The sizes of the plates vary, although in linseed oil manufacture they are generally designed to hold a cake 13 x 32 in. or 16 x 34 in.

Drainage is secured by cutting grooves or oil channels close to the edges of the plate which are pitched toward the rear where they connect with down spouts that conduct the oil to the receiving troughs at the floor level behind the presses. Some presses are tilted back to give a fall sufficient to cause the oil to run in that direction.

Suspension of the plates, when pressure is released, is usually obtained by the use of links, each set of which carries the plates beneath, unless sectional supports are provided. The links are of two sorts, the plain open type, or the square, flat-headed type. The former are fastened to T-headed bolts screwed onto the edges of the plates while the others are slipped into notches out in the sides of the plate near the ends. Often the plates are divided into groups so as to lighten the load upon the links. This is accomplished by having lugs on the plates which engage the heads of screws set at proper intervals in the columns.

Another very effective method of support is by a step ladder or inverted V-shaped device the feet of which are fastened into the columns near the bottom plate, while the top is attached to the head block at the center of each side. The legs of the ladder are of steel plate and are notched at measured intervals.

Into each side of a plate are screwed two headless bolts so placed that each engages its own step of the ladder. Thus, each plate is supported by a rigid frame and the load caused by a group of plates is done away with. The wear on the steps is slight and easily adjusted, for when the press is up the supporting frame can be removed and repaired without removing the plates, while when the links are used each plate must be removed whenever it is necessary to shorten them.

It is important that the links be kept true, for they control the space between plates which must not fall below a minimum or the cakes cannot be placed easily. It is a too frequent occurrence, especially in new mills, to have the cake space shortened by wear or lengthening of the links so that the bottom cake is not easily put into proper position causing uneven pressure and the breaking of the platen. It is false economy to reduce the cake space in designing a press, for time is lost during loading and cakes are not evenly placed causing them to lie at angles instead of parallel to each other. This means uneven pressure and loss of oil. With ample working space the molded and wrapped cake is quickly placed into proper position, thus lengthening the time of pressure and insuring even pressure throughout.

CAPACITY OF PRESSES

Primarily the capacity of the press is controlled by the number of plates comprising it, though variations in operation, to be discussed later, are factors of the capacity of any given press.

The number of plates in the presses of American mills varies, generally between sixteen and twenty-six. The obvious objection to the small presses is low capacity, for when reduced below twenty plates little if any gain in yield results. When the large twenty-four and twenty-six-plate presses are employed it is hard to find men tall enough to reach the top plate and agile enough to place the bottom one quickly. A slight additional expense is noted with large presses caused by the destruction of the ends of the slip pans which are broken by the exertion of downward pressure before they are entirely out from between the plates.

When a large number of cakes are replaced the press is down a longer time and consequently cooled more. The temperature of the press and its contents has an important bearing upon the yield, consequently the lower it drops the lower is the extraction. It may be said that the meal can be raised to a higher temperature, but this is an undesirable thing to do for there is a limit beyond which meal ought never to be heated.

Further, when the number of plates is large, there is a correspondingly great mass through which the pressure must be exerted. When this goes beyond a maximum excessive cushioning occurs and low yield results. The extent of the loss caused by the use of large presses is an unanswered question, though one capable of easy solution.

No data are available which show, with all other variables constant, the effect that the increase in the number of plates has upon the yield of oil. What might be called circumstantial evidence—that is, the comparison of the percentages of oil in the cakes produced in mills known to have large and small presses—shows the latter to be more efficient. However, other factors enter which could account for the difference. It is the opinion of many versed in the operation of linseed mills that the twenty-plate press combines the greatest number of elements that make for efficient extraction.

PRESS MATS

A much mooted subject in linseed oil manufacture is that of press mats. These are mats woven from rope of coarse hair such as that from the manes and tails of cattle. They are fastened to the plates, which are often roughened to prevent slippage. Frequently the mats are attached to a screen of coarse mesh and heavy wire, which are in turn made fast to the plate. Mats of malleable iron are also used, which are bolted to the plate. In many mills mats are used on both top and bottom plate; in others on but one, and in still others none at all are used.

The statement has been made that the mat was originally used to form a porous material through which the oil could run after leaving the meal. Practice, however, has proved that the presence or absence of mats makes no difference with the flow of oil.

Supporters of the use of mats now claim that they tend to make the transmission of pressure equal at all points. If properly molded, the cakes will lie evenly on the plate and consequently be subjected to an even pressure without the assistance of a mat. It is also hard to see how a mat can even up the exertion of pressure in view of the normal causes of that action.

In answer to the statement that mats rigidly grip the press cloth thus preventing slippage and uneven tension on it, can be placed the experience in two mills which has been directly communicated to the writer. In one there were two sections, one equipped with double hair mats and the other with none. After years of parallel operation the superintendent made the statement that press cloth costs were the same in both cases.

In another mill strips of sheet iron were placed over the mats with a consequent slight reduction in the cost of press cloth.

Hair mats are poor conductors of heat, hence, it is said, the temperature of the meal will be reduced to a lesser extent during the pressing operation, and therefore the yield of oil will be increased. In the previously mentioned mill that section equipped with hair mats produced no more oil than did the bare plate portion.

With only conflicting statements available, and these based upon data doubtless modified by other variables effective during the period of observation, it is impossible to state positively what the hair mat does or does not accomplish. The objection to their use is cost. They are expensive and need frequently to be replaced.

The mat does serve to guide the slip pan into proper position when the soft cake is slipped in between the plates, thus insuring equal pressure and parallel plates. The malleable mat accomplishes this without expenses save the initial cost. When bare plates are used they are corrugated or cut at right angles to prevent slippage while under pressure.

Another objection to mats is that they are thick enough appreciably to reduce the cake space in a given column height. When bare plates are used there are fastened along the sides near the edge strips of metal beveled on the inside. These are to serve as guides in filling the press and also to prevent the meal from being pressed out at the edges. If they are made high enough effectively to guide the pan they cut the press cloth.

THE PRESS CLOTH

One of the relatively large items of expense in linseed oil manufacture is that of press cloth; that is, the material which is wrapped about the cake when molded. It is usually woven from camel's hair because of the elasticity of that fiber and its ability to retain its strength and form under high pressures and temperatures. At present, this material is very high in price and is scarce as well. Various mats of wool and mixtures of wool and camel's hair cloth are being tried, but preference would still be given to the camel's hair. Press cloth of human hair is now available. First tests of this showed up very well against camel's hair.

The avoidance of those elements of press room practice which make for the rapid destruction of press cloth is essential to good work. Trouble can start in the heater for water balls, or an uneven heating or wetting of the ground seed will gum up the cloths in spots, thus preventing the flow of the oil through them and causing disruption at that point. Meal not uniformly temperated does not pack evenly, producing tension on the cloth. If too much moisture is in the meal as molded it forces its way into the cloth, fills up the interstices with consequent tension and tearing. Too high a temperature will reduce the tensile strength of the fibers and breaking will result.

If the "former" does not produce a cake of uniform density the uneven packing in the press causes stresses which result in torn cloth. The press room foreman must watch the rate of ram travel after the oil begins to flow, for if it is too fast the volume of oil set free, much of which passes to the edges through the cloth, will tear it. This must be watched with extreme care when the pressing takes place at a low temperature as in starting up after a shut-down.

The torn cloths are darned, patched, mended and pieced until the waste comprises short strips which are beyond redemption. These are but typical causes for too rapid destruction of press cloth. Constant watching by intelligent men is necessary to keep down this item of expense.

THE FUNCTION OF THE PRESSURE, CAKE WEIGHT AND TIME

In the pressing of the tempered meal in a given press there are three variables which are functions of yield and capacity; one is the pressure. That most generally used is from 3500 to 4500 lb. per square inch. A gage should be placed on each press so that close watch can be kept for unexpected variations.

Another variable is the weight of the molded cake. Practice varies between those weighing 10 lb. after pressing and those of 15 or 16 lb. When the cakes are thick the mass of meal under pressure is great, there is more tendency toward uneven packing and the cushioning in the press is at a maximum.

As in the case of the number of plates in a press there are no authentic data available on the effect of variations in the cake weight upon oil yield, and so again we draw our conclusions from the analysis of light and heavy cake without knowing that weight was the only variable. The light cake gives the lowest average oil content. The minimum weight produced is 10 lb. To keep as close to that as possible is a good practice.

The third variable is time. The presses are usually arranged in groups of six, one of which is operated by the two or three men who work together. Assuming such to be the case the pressings per hour are expressed as six on six, seven on six or five on six, as the case may be.

In the first case the pressure is exerted for sixty minutes less the time required to discharge and charge, which varies between five and ten minutes with the dexterity of the men. The seven on six method allows but fifty-one minutes, while five on six permits of seventy-two minutes under pressure less changing time.

In a mill which operated six on six part of the year and seven on six the remainder, a careful analysis of the cake produced is always kept. A tabulation for a period of several years showed that the longer time increased the oil in the cake by one-half of 1 per cent. With cake at $30 per ton and oil at 50 cents per gallon, ½ per cent reduction in the oil content of the cake makes a gain of 2.5 cents per bushel of seed, or $3.25 per press per day when it is run for yield and not capacity. To-day the figure would be about 9 cents per bushel.

As a result of a study of the data on hand supplemented by experience the writer would use, with the feeling that he was not far from the most economic practice, one roll for each two presses, an 84-in., three-high heater for twelve presses, or possibly a 72-in. to six presses, a hand-operated hydraulic former and twenty-plate presses in which 10-lb. cake would be produced at the rate of six pressings per hour on each six presses.

The obvious conclusion to be drawn from the statements made is that the manufacture of linseed oil is controlled in an uncertain empirical manner. It is possible that a system could be worked out by accurate

observations of the effect of various changes in operation and by a scientific study of the underlying reactions and mechanical principles involved which would minimize the effect of variations in the seed and thus render extraction more efficient. With the present and probable prices of oil and cake for the near future one would not have to make much of an improvement to pay large dividends upon the investment required.

DISPOSING OF THE CAKES

When the cakes are removed from the press they are stripped—that is, the wrappers are removed. This is done either by hand or by machine. It is hard, disagreeable work, for at the start the pull is mostly on the fingers and the cake is hot. The mechanical strippers in use simply catch the end of the cloth when it is placed in contact with a revolving shaft about which it is wound.

The stripped cake is now sent to the trimmer, where the soft edges of high-oil content are cut off. Trimmers are of two types, those with revolving knives and those with stationary knives, both having spring tension devices. There is little choice in effectiveness. The rotary knife takes more power and is more complex, but the trimmings from it do not need regrinding, while those from the stationary knife machine do.

The depth to which to trim depends upon local conditions. It should be determined at each plant from its operating cost so that the yield of oil from the trimmings when recrushed will be enough to repay the expense of handling. If trimmed too deep the oil content will be so low that the oil recovered will cost more than it is worth, while if too much oil is left in the cake by shallow trimming oil loss results. About 12 per cent oil in the trimmings is right when normal conditions obtain.

If to be sold as such, the cakes are packed generally in second-hand sugar bags and shipped. A hydraulic machine takes a pile of cake from the trimmer and pushes it into a bag, which is loosely filled, then the bag is placed under a packer which jams single cakes into it until the strain is near the breaking point.

When ground to meal the cakes are run into an impact mill direct or into a breaker and then an attrition mill. The first method is generally considered the more economical.

THE OIL

When the oil runs from the presses it is caught in settling troughs or deep metal boxes in which coarse particles settle to the bottom. From here it goes to filter supply tanks. Filtration is accomplished by the plate and frame press. The filter medium varies from light sheeting to heavy duck and from light to heavy paper. At some mills the oil is filtered warm through cloth, sent to storage and then refiltered just previous to shipment. With many the second filtration is omitted. Others allow the oil to cool without the first, or, as it is termed, "scalping," filtration, and then pass through cloth or paper.

Any one of these practices will remove the suspended particles of seed and deliver a clear oil. However, moisture and materials taken into colloidal solution from the seed are present in larger amounts in warm oil. They gradually precipitate as the temperature falls forming what is known in oil parlance as "foots." Therefore the temperature of the oil at time of filtratin is an important function of its quality. If single filtration is determined upon, excellent results may be had by allowing the oil to cool and then passing it through cloth or paper, preferably the latter.

The quality of raw linseed oil is obviously dependent upon the manner of its filtration. Further, too high a temperature in the heater darkens the oil and causes it to dissolve more material from the seed. A hot pressed oil will darken more under heat, will not bleach so well in the refinery and shows other deleterious effects of the high temperature.

The quality and cleanness of the seed have a marked influence as well. Seed selection for oil quality is unknown, because no means at present exists to connect the characteristics of perfect flax seed with the quality of oil contained.

An investigation of this problem is at present under way. We are hopeful of results that will enlighten us upon the effect of seed strain, soil and climatic conditions, upon the quality of oil and possibly enable prediction from an examination of flax seed of the quality of its oil.

The manufacturers employing linseed oil demand of that product specific qualities such as pale color, high content of fatty acids, proper action in the varnish kettle and high speed of polymerization when subjected to high temperatures. These qualities are imparted by chemical treatments of various sorts which are more or less secret and which involve only simple mechanical equipment and operation.

During the last five years the average oil content of clean seed received by a mill on the seaboard was 39.02 per cent. North American seed comprised 75 per cent of that crushed, the rest being South American. Assuming that the cake will contain 5.5 per cent, an amount attainable by good practice, the theoretical yield of a cake will be 36.15 lb. and of oil 19.86 lb., or 2.64 gal. of 7½ lb. each. The word "theoretical" is used because there is a manufacturing loss of about 2 per cent. This is nearly all due to the evaporation of moisture, though some is accounted for by soakage, dusting and similar causes. If the moisture in the seed is high the loss will be above normal for oil carries very little water, so that the cake must contain all that is in the seed or a loss is inevitable.

Chicago, Ill.

German Alcohol.—At the annual meeting of German spirit manufacturers, recently held in Berlin, it was stated (according to the *Chemical Trade Journal and Chemical Engineer*) that all the departments of the manufacture had been busy with general and special war work. The outlook for the future was not considered favorable, since for years to come potatoes would more than ever be wanted as food; a great many of the large farms used to rely more upon potato-spirit distillation than upon farm produce. For incandescent burners alcohol with 15 per cent of benzene is being utilized; in fuels, alcohol with 25 per cent of benzene is substituted for petroleum. The sale of petroleum for illumination is at present forbidden in Germany. Acetone fermentation works had been opened in Arenberg, but the technical difficulties of the process had not been quite overcome yet; it is also intended to manufacture by fermentation of butyl and other alcohols.

The Recovery of Potash from Beet Sugar House Waste Liquors*

By H. E. Zitkowski

General Chemist, American Beet Sugar Company

The recovery of the residual values from beet sugar waste liquor has been the subject of serious investigation even prior to the war. However, the abnormally high potash prices of the past few years have brought about renewed efforts in this direction.

The fundamentals for a consideration of this problem are the following:

During the 1916 season approximately 6,000,000 tons of sugar beets were produced in the United States. In all probability a materially greater tonnage will be produced this year, and the possibilities for increased production in the immediate future are promising, though this phase of the problem is so intimately related to the tariff, the agricultural labor supply, and ruling prices of other agricultural products that prophecy is fruitless.

The composition of the beet, and therefore its content of potash, is variable from season to season and in different localities and soil conditions. The following analyses of beets from three widely separated localities in the United States can serve as a basis.

	Colorado Per Cent	California Per Cent	Wisconsin Per Cent
Moisture	78.36	63.99	74.37
Dry substance	21.64	36.01	25.63
Ash (carbonate)	0.89	0.88	....
Total nitrogen	0.199	0.254	0.1817
Sugar	15.40	25.60	18.7
Mineral matter in per cent in beets:			
Cl	0.102	0.065	0.040
SO_3	0.028	0.034	0.024
P_2O_5	0.046	0.121	0.023
K_2O	0.320	0.269	0.320
Na_2O	0.097	0.106	0.089
CaO	0.022	0.078	0.041
MgO	0.058	0.051	0.047
$Fe_2O_3Al_2O_3$	0.042	0.014	0.027
SiO_2	0.005	0.016	0.036

Both the California and Wisconsin samples were several days in transit to the laboratory at which the analyses were made, and undoubtedly lost considerable moisture by evaporation which consequently increased the percentage content of dry matter. Aside from that the California sample was abnormally high in sugar content.

From an agricultural and economic viewpoint—aside from the sugar—the nitrogen, phosphoric acid and potash content of the sugar beet is of more than passing importance.

Accepting the average of the three analyses herein reported as the average for the entire production, the 6,000,000 ton crop of beets of 1916 contained of

Nitrogen ..... 12,700 tons
Phosphoric anhydride ..... 3,780 tons
Potassium oxide ..... 18,180 tons

Investigations indicate that in extracting the sugar values by the diffusion process approximately 60 per cent of the nitrogen and 90 per cent of the phosphoric acid and potash content are extracted with the sugar and pass into the process, the rest remains with the pulp. As this pulp now is completely utilized for live stock feeding purposes, the plant food values of this pulp are not lost to agriculture except in so far as farm yard manures are inefficiently utilized.

Of the plant food values extracted and now in the juices phosphoric acid is completely eliminated as calcium phosphate, and to date largely wasted. A part of the nitrogen content is eliminated as coagulated protein and otherwise, together with the phosphoric salts. The potash, however, is not eliminated from the juices by the usual processes of purification and is found in the final molasses, that is the mother liquors, from which sugar cannot be further recovered by direct crystallization, and for this the presence of potash salts are partly responsible.

The production of molasses from beets is somewhat variable from season to season, but an average percentage production for the United States will be somewhere between 5.5 per cent to 6.0 per cent on beets. With a 6,000,000-ton crop of beets this totals to 330,000 to 360,000 tons.

A study of a series of thirteen samples of American beet molasses as reported in Volume 18, No. 4, of *Sugar*, indicates an average content of 1.69 per cent nitrogen and 4.66 per cent of potassium oxide, K_2O.

On this basis the beet sugar molasses production of the past campaign contained between 15,400 and 16,700 tons of K_2O, which checks fairly closely with the figures above estimated. Of the total beet molasses production, under normal conditions perhaps 5 per cent, under present conditions double this amount or more, is used in alcohol production and the still residues, containing the potash, are concentrated and usually enter the fertilizer trade and are therefore, not lost to the general economy.

Approximately 40 per cent of the total molasses production is used for stock feeding purposes, in part direct as such, but by far the greater part is mixed with some absorbent feed, frequently beet pulp either fresh or dried, and also many of the fodders. The potash values in this case are recovered in proportion as the manureal values from these feeding operations are recovered.

The remainder of the United States molasses production, perhaps 45 per cent of the total, during the past season from 148,000 to 152,000 tons, is desugarized, that is sugar is extracted in marketable form. It is this portion of the beet crop that contains the possibilities of potash production in commercial form at the sugar factories.

The process now used almost exclusively in this country in extracting sugar from this molasses is known after its inventor as the Steffens precipitation process in which sugar is precipitated as tri-calcium saccharate.

Essentially the procedure is as follows:

Molasses of about 80 per cent solids is diluted to 10 per cent to 12 per cent solid content, cooled to about 15 deg. C. and under suitable means for cooling and stirring, finely powdered calcium oxide is dusted into the solution. If the conditions essential to the process are adhered to 90 per cent or more of the sugar is precipitated as a calcium compound and is removed from the mixture by filtration.

The filtrate, now with a content of solid matter of 5 per cent to 7 per cent contains practically all of the potash originally in the molasses and also variable percentages of sugar not precipitated above.

The sugar in solution is probably present in the form of dicalcium saccharate $C_{12}H_{22}O_{11}\cdot 2CaO$. If this cold filtrate is heated to 85 deg. C. approximately 60 per cent of the sugar in solution is precipitated as a calcium saccharate probably according to the following reaction:

*A paper presented at the Buffalo meeting of The American Institute of Chemical Engineers, June 22, 1917.

$$3C_{12}H_{22}O_{11}\cdot 2CaO \leftrightarrows 2C_{12}H_{22}O_{11}\cdot 3CaO + C_{12}H_{22}O_{11}.$$

The reaction is reversible and on cooling the saccharate formed dissolves. It is necessary to filter at the precipitation temperature.

This, known as the hot saccharate process, is now quite generally used to recover additional sugar values from the solution which are not readily and economically recovered by the first step or cold process.

The filtrate, now known as Steffens hot waste water, still contains from a few hundredths to four or five tenths of a per cent of sugar, some lime and practically all of the potash and most of the other non-sugars present in the molasses. This is the waste liquor forming a potential potash supply.

In several instances, where the sugar company controls agricultural lands in quantity adjoining the factory, these waste liquors, together with other residues, are used to irrigate the lands. This is perhaps the most economical method of utilizing the residual values as all of the potash and phosphoric acid and nearly all of the nitrogen of the beet can be returned to the soils, but this is practical only in isolated instances, and only about 8 per cent of the total beet crop is handled in this manner.

In still other of the irrigated sections where the residual waters are discharged into existing streams and the streams are subsequently diverted for irrigation purposes some of the values may be inadvertently utilized, but in any event the losses to the economy of the state must be very considerable by this method of disposal.

In most cases the waste residues are sent into settling basins, the clear effluent of which reaches the streams and is carried away. Efforts had been made even before the war to recover these values, and owing to the stimulus of high potash prices of recent years the work in this direction has been followed with more than usual vigor. However, the problem has its difficulties.

The hot waste water as produced is very dilute containing 96 per cent or more of water, it is necessary to concentrate it. As produced it contains 0.2 to 0.5 per cent of free lime, CaO, which will foul the evaporating surfaces if not removed. This is readily enough accomplished by carbonating (injecting CO_2 gas) and filtering. (It might be stated that during the past campaign in one case these waters were concentrated by the direct gases from an oil fire passing upward through a sheet metal gradier over which the waste liquors flowed. In this case removal of the lime was not necessary as the heat transfer was brought about by direct contact without an intervening metallic surface. This method of evaporating is prohibitive as to costs under normal conditions.)

The carbonated and filtered waste water varies in composition with the season, locality, and factory practice, but the following is typical.

	Per Cent
Moisture	97.00
Dry substance	3.00
Carbonate ash	1.00
Sugar	0.30
Organic non-sugar	1.70
Nitrogen	0.16
K_2O	0.35

This indicates at once that the content of values is low, the cost of evaporation comparatively great, and also that under normal conditions, when the value of a unit of nitrogen is two or three times that of a unit of potash, the nitrogen values are as great or greater than those of the potash contained in these waters. Up to a content of 50 per cent to 55 per cent dry substance this water can be readily enough concentrated in multiple-effect evaporators, and quadruple and also quintuple-effect evaporators have been used very successfully. With a content of more than 55 per cent dry matter the liquor begins to salt out and foul the heating surfaces. However, beyond this point the material can be readily enough concentrated still further, and brought to a dry state by the use of one of the various types of vacuum drum dryers. The trouble is to keep the material dry.

The dried material containing 10 to 12 per cent of K_2O and 5 per cent N. is so exceedingly deliquescent and absorbs atmospheric moisture so readily that it becomes fluid in a very short time.

Various absorbents have been used to overcome this difficulty, one of the most successful being dried slaughter house wastes which incidentally are deficient in potash, so the two materials complement one another. Ultimately this may prove to be a direction in which considerable quantities of the sugar factory waste waters will be utilized, but unfortunately only few beet sugar factories are now located within a reasonable distance of the meat packers and the cost of freight enters.

In some localities small quantities of 50 to 55 per cent dry substance have been disposed of in tank car lots directly to the agricultural industry as a liquid fertilizer. In other instances it is urged to sell the liquid fertilizer direct to the farmer, the farmer to saturate his barn yard manure with the concentrate and thus use it. It is doubtful whether material quantities can be disposed of in this form at present.

With present potash prices the nitrogen values have lost their relative value with the result that in at least one instance these have been sacrificed in order to obtain a product comparatively high in potash content, which would permit its shipment considerable distances to the potash-consuming centers.

When the Steffens water is concentrated to about 55 per cent dry substance owing to its high content of sugar, and other organic matter, it can be quite readily ignited and charred, its own content of combustible matter then furnishing most of the necessary heat. The char, or crude ash thus produced contains from 30 to 35 per cent of potassium oxide, but only traces of nitrogen. This procedure is economically justifiable only with present potash prices. In other directions experiments are being made toward a recovery of the potash salts in comparatively pure form, and still save the nitrogen values.

That roughly covers the efforts made in the recovery of the values of the beet sugar liquor residues.

Technically the recovery of the potash values from these liquors is a comparatively simple and perfectly feasible problem. It is simply one of evaporating the dilute liquors as economically as practical, charring the residue to produce the crude ash and leaching and recrystallizing if this is desired. The quantities of water to be evaporated, however, are large, the necessary equipment costly, and commercially such a procedure has possibilities only during war prices.

Now it is true that almost any sugar factory could have paid for a potash recovery plant in one year with present potash prices, but the war may end any time and leave a lot of very costly equipment on hand, es-

pecially as the cost of such equipment, evaporators, boilers, etc., is abnormally high at present. Then also a beet sugar factory operates seasonally only, the average length of the operating season is only about 100 days, and the earnings must be made during this short period. But at that some progress is being made, and at least one concentrating plant is under construction and several others under consideration and more of the values will be recovered during the 1917 campaign than during the past.

However, in these instances a recovery of all the values in the liquors is aimed at, not the potash values only. This will be touched briefly below.

Approximately the disposition of the potash in the sugar beet crop grown in the United States at present is as follows:

Returned to farms in pulp.....10 per cent
Found in molasses produced.....90 per cent

The potash found in molasses is distributed as follows:

To alcohol plants.....10 per cent plus
Used as molasses feeds.....40 per cent plus
Desugarized .....45 per cent plus

This only leaves under control of the manufacturers about 40 per cent of the potash content of the beet which on the basis of a 6,000,000-ton crop amounts to between 6800 and 7500 tons of K_2O.

This quantity is now disposed of as follows:

Directly to the soil as factory sewage..20 per cent
Concentrated to 50-55 per cent dry substance and sold to fertilizer factories 5 per cent
Concentrated and calcined to a crude ash ..... 5 per cent
Discharged into streams and representing the stock of values now lost.....70 per cent

Thus far the subject has been considered from the angle of recovering the potash for the chemical industries or the potash and nitrogen as fertilizers only. That does not by any means exhaust the possibilities. Beet sugar molasses and therefore the waste water contains a great number of substances which in themselves are valuable or may serve as the mother substance for valuable product. The possibilities can here be touched on only very briefly.

Even in the case of potash and nitrogen it appears from the experience of Europe that the general economy is served best by combining these into a more valuable product. From Germany it is reported that by the Bueb process of destructive distillation the waste liquor of molasses desugarizing processes operating by the strontium process, in that country, produce annually 5000 tons of potassium cyanide and 5000 tons of ammonium sulfate. Steffens waters can be similarly utilized and a United States patent has been granted for such a process.

The molasses waste liquors contain a whole series of organic acids valuable to industry which can be recovered.

The nitrogen of these waste liquors occurs in various forms, partly as a plant basis of which the principal is betain, which has found some application in medicine. A large part of the nitrogen content exists in the form of amido acids. These it has been shown by Effront can, by suitable fermentation processes, be split into ammonia and a mixture of volatile fatty acids, acetic, propionic, butyric. Recent investigations in this country indicate that a mixture of the high boiling point ketones valuable in cellulose technology, can be prepared from this liquor.

Ehrlich insists that the amido compounds present in considerable quantities in beet molasses waste liquors are the mother substance of fusel oil, more particularly amyl alcohol, and suggests extracting these compounds and utilizing them to increase the fusel oil production. This indicates only a few of the possibilities. While it is not claimed that beet molasses may yet prove another coal tar, chemically it may be almost as interesting.

But little has been done in developing the waste liquor values in this country. The reasons are various. Not the least lies in the fact that sugar is a sort of national and international political football. Between duties, bounties, premiums, special international agreements as the Brussels Conference, and competition with the tropics, the beet sugar industry in the United States has never felt sufficiently safe to venture into new directions.

At the outbreak of the present war the outlook was particularly dark. The tariff had been lowered, and a duty free sugar clause enacted to go into effect May 1, 1916. Fortunately, this latter clause was repealed before going into effect.

What the development of the future may be will depend more upon legislation following cessation of hostilities rather than present high prices, and in this respect the beet sugar industry is not differently situated than most other chemical industries in this country.

Metallurgical Processes in the Foundry*

Use of Ferromanganese, Ferrosilicon, Chills and Iron Molds

By Alexander E. Outerbridge, Jr.
Metallurgist, William Sellers & Co., Inc., Philadelphia, Pa.

Before proceeding to the subject proper of my paper I wish to make a little confession. After almost a lifetime spent in the study and daily practical application of investigations in metallurgy on a somewhat large scale, more particularly in cast iron in industrial works, I feel sometimes that I know less about the subject to-day than I thought I did nearly 40 years ago. This is not surprising, however, for I believe it is the universal experience of investigators that the more one delves into Nature's mysteries the more one finds to discover, thus relatively, the more one studies the less one feels that he knows.

The history of the study of astronomy affords, for example, a striking illustration of this. Long before Galileo pointed the first telescope at the heavens, in 1609, the old monks had, with infinite pains, mapped out the firmament and recorded the positions of all the stars then visible to the eye of man and they naturally thought that their charts were complete. But the moment the new and more powerful eye of the telescope was pointed at the blue vault hundreds of thousands of starry worlds came into view whose existence had never before been suspected, revealing glowing stars so far distant that the light from them must have started on its long journey centuries before the Christian era.

*An address delivered before the Philadelphia Foundrymen's Association on June 6, 1917.

So it is with more mundane affairs, such as the study of the composition and physical properties of metals and alloys. Chemistry has told us pretty well the elements and proportions of the components of complex alloys, like cast iron, but that is, after all, a very dim light to guide us and it only reveals a few of the most conspicuous properties, leaving many others yet to be discovered by those who come after us.

In comparatively recent years the microscope has supplemented chemical analysis and has given us much valuable information regarding the effect of heat treatment upon the structure of metals especially iron and steel. The spectroscope also has shown us the signatures of all metals, written in fine lines of colored lights that cannot be imitated or disguised.

The specific gravity of alloys and the remarkable changes in density that may be effected by heat, as in the case of the extraordinary growth of gray cast iron when subjected to repeated heating and cooling* or the equally remarkable change in density caused by sudden cooling from the liquid to the solid state, as shown in the tread or periphery of a chilled cast iron car wheel are subjects of great interest for study. These are but a few of the aids to the study of metals now available and a vast unexplored field yet remains for the future investigator.

The difference between wrought iron, steel and cast iron, is commonly attributed mainly to the proportion of carbon, silicon, sulphur, phosphorus, manganese, together with a few other elements, composing these alloys, and the analytical chemist has no difficulty in determining the relative proportions of these elements with sufficient accuracy, but beyond this lies a region of which he knows nothing. He does tell us, it is true, that carbon exists in iron in two different forms, "combined" and "graphitic," but how many other forms of carbon may there be united with these other elements?

Take pure carbon alone, we already know of no less than three totally different forms, viz.: (1) A soft, intensely black substance called "lamp black" which the chemist tells us is 100 per cent carbon; (2) An intensely hard transparent crystal, the diamond, also 100 per cent carbon; (3) Pure plumbago or graphite, an unctuous material, quite different from the other forms, also 100 per cent carbon. There is absolutely no chemical difference between them.

In like manner it is known that pure silicon exists in three distinct forms or amorphous conditions. So it is with some and probably all of the other elements combined with iron.

The chemist or physicist is not yet born who can, by any known methods of investigation, state with positiveness—or even guess at—the various possible forms or combinations of the elements composing these alloys and it is not, therefore, surprising, that oftentimes the analyses of two specimens of iron, steel or other metals, will be nearly alike, when the physical properties are very different.

*Two bars of gray cast iron were shown that were cast in one mold from one ladle and were both originally the same size, viz., 14 13/16 x 1 x 1 in. The specific gravity of the metal was 7.21, making 450 lb. to the cubic foot. One bar had been permanently expanded or caused to "grow" while in the solid form to 16¼ x 1⅛ x 1⅛ in., making an increase of 40 97/100 per cent. The specific gravity of the expanded bar is 5.54, making 350 lb. to the cubic foot. These identical bars were first shown before this association in 1903. Other bars of gray cast iron have been caused to increase in cubical dimensions over 50 per cent by repeated heating and cooling, still retaining their metallic qualities.

These are a few of the problems I have been studying for nearly forty years, but you are, of course, interested mainly in the practical side of such questions, hence we will now descend from the realm of theory to that of practice.

A number of cast iron test pieces made to illustrate an address given by myself before the Franklin Institute in 1888 on "The Relation Between the Physical Properties and Chemical Constituents of Pig Iron" are shown in Fig. 1. Here are shown test pieces cast

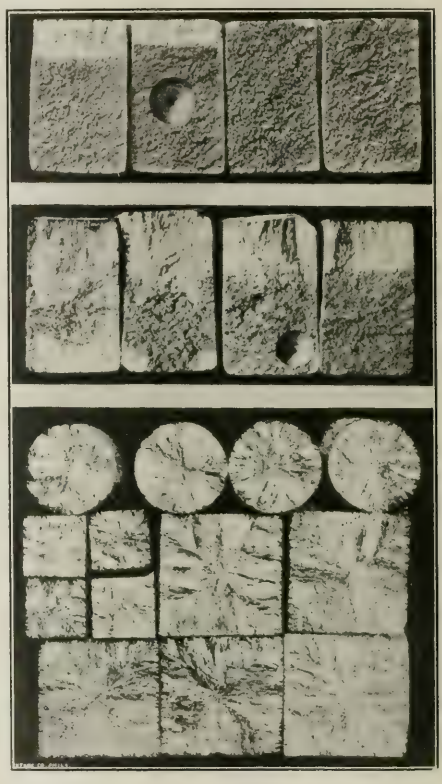

FIG. 1—TEST PIECES CAST IN SAND AND IRON MOLDS

from eight different melts of iron. The two upper rows were poured in green sand molds having an iron chill block on one face.

The test bar at the right hand upper corner shows merely a "skin chill' on the part cast against the iron block, the next bar shows a very little more chill, the other bars show increasing proportion of white iron on the upper faces and two show white iron on the lower faces also. Beneath the eight test pieces cast in sand, you see nine square and four round test pieces, all perfectly white iron, showing very clearly that the crystals are always formed at right angles to the surface of the mold. These test pieces were cast in iron molds from the same ladles of iron as the other bars and you will notice that all are equally white, notwithstanding the fact that the bars cast in sand with an iron chill block on one face vary enormously in depth of chill.

These iron molds may be called "chill magnifiers." I

have used similar chill cups daily for detecting chilling properties in soft foundry irons for over thirty years, and they have proved to be of the greatest value in detecting chill that would not otherwise be suspected in such iron mixtures.

The main difference in composition of the eight melts of iron shown in this plate was found to be in the relative proportion of silicon.

The test piece showing a mere trace of chill has over 1½ per cent silicon, the one showing the most chill has about 6/10 of 1 per cent silicon, the other test pieces contain silicon ranging between these extremes.

The manufacture of chilled cast iron car wheels, (Fig. 2) a purely American invention, to which the development of railways in this country may be said to owe its rapid progress in the early days and to which it is still largely indebted for freight traffic, was rendered possible by the practical application of the chilling property found in our cold blast charcoal irons, and its continued success to-day is dependent largely upon the skill of the chemist to simulate those natural qualities by other means, long after cold blast charcoal iron has gone out of existence.

My first investigation of this peculiar property of cold blast charcoal iron (and of some grades of anthracite and coke iron) dates back to the year 1876, when a fine exhibit of chilled cast iron car wheels at the Centennial Exhibition first attracted my attention. One of the wheels was broken to show the fracture; the plate and brackets were dark gray, while the tread of the wheel was white as silver. On inquiry I learned that the white iron tread was formed by sudden cooling of the metal cast against a heavy iron "chill ring" and that while the plate and hub of the wheel cast in a green sand mold were quite soft the tread was hard as steel.

At that time I was making some specific gravity determinations of various metals in the assay laboratory of the mint, where I was an assistant, and samples of the white iron forming the tread of a wheel and of the dark gray iron forming the body were furnished to me for examination. I was astonished to find that the white metal weighed about 60 lb. to the cu. ft. more than the gray iron portion of the same casting.

This served to explain the abnormal cooling strains in a chilled casting of this character, necessitating prolonged annealing, or very slow cooling, to enable the molecules to adjust themselves gradually and thus relieve the strains.

These investigations led to others and for a period of eight years I was daily engaged in the study of the metallurgy of chilled cast iron car wheels and their manufacture. It was customary to cast, each day, in the car wheel works where I was engaged as metallurgist, a large variety of chilled car wheels ranging from full size, double-plate passenger and freight wheels, 33 in. diameter, street car wheels (usually of spoke pattern) down to small and light mine car wheels.

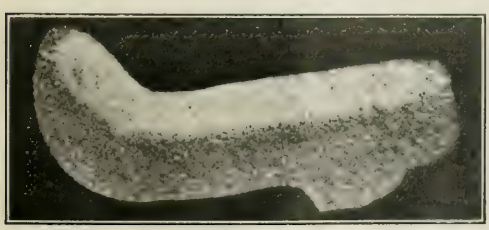

FIG. 2—SECTION OF 33-INCH CAR WHEEL CAST FROM TREATED IRON SHOWING FINE WHITE CRYSTALS AND DARK GRAY

It was not possible to pour all of these from one mixture of iron for the metal suitable for the heavy wheels was too high chilling for the smaller wheels. This necessitated melting soft iron every day in a small cupola to mix in varying proportions with the regular iron in separate ladles.

To overcome this expense, if possible, by altering the character of the iron in individual ladles, after delivery from the cupola, a great many experiments were made (1880-4) with aluminium (then costing $8 per pound), spiegeleisen and 80 per cent ferromanganese, granulated or powdered, added in small quantity to the metal in the ladles.

The effects produced by aluminium and spiegeleisen were in the right direction though they were not sufficiently marked to be valuable but it was then found that when powdered 80 per cent ferromanganese was added in the proportion of 1 lb. to 600 lb. of iron in a ladle, a most remarkable change was immediately produced in the character of the molten iron in the ladle. The first publication of these experiments was given in the address already alluded to, printed in the Journal of the Franklin Institute, March, 1888, and was as follows:

"A remarkable effect is produced upon the character of hard iron (i.e., high chilling iron) by adding to the molten metal, a moment before pouring it into a mold, a very small quantity of powdered 80 per cent ferromanganese, say 1 lb. in 600 lb. of iron. The result of several hundred carefully conducted experiments which I have made enables me to say that the transverse strength of the metal is increased from 30 to 40 per cent, the shrinkage is decreased from 20 to 30 per cent and the depth of the chill is decreased about 25 per cent, while one-half of the combined carbon is changed into free carbon."

Prior to this time manganese had always been regarded as a hardening element in cast iron, and the surprising claim that when added in a ladle of high-chilling car-wheel iron it had an opposite effect at first met with incredulity, but in course of time its use became almost universal, and I believe it still is used very largely in the manufacture of chilled cast-iron car wheels. No application for patent rights was made for this process.

Ferromanganese, when added in powdered form to a ladle of molten car-wheel iron, acts as a deoxidizing and desulphurizing flux by reason of the strong affinity of manganese for oxygen and sulphur, but it is only efficacious when added to iron that is comparatively low in silicon (less than 1 per cent) and high in combined carbon.

It is absolutely useless, if not positively harmful, when added to foundry mixtures carrying over 1 per cent silicon and but little combined carbon, yet I know that 80 per cent ferromanganese has been sold to foundrymen for treatment of their foundry iron mixtures during the time when the alloy could be bought for a few cents a pound. Its present price is prohibitive, except for special purposes.

The use of ferromanganese as a flux in ladles in car

wheel manufacture is of enormous value to that industry, its abuse through ignorance or failure to understand its proper functions must have led to disappointment when added as a flux in ladles of foundry iron by those who do not understand or appreciate the radical difference between car-wheel iron and foundry iron, whether soft or hard.

While the manufacture of chilled cast-iron car wheels requires very accurate control of the chilling property of the metal, it is of far more uniform character than the iron needed for the great variety of castings, ranging from a few pounds up to perhaps 30 tons or over that must be melted often in one day in the large machine tool works with which I am connected as metallurgist. It is customary, therefore, to group all the small work needing soft ductile iron so that it will be cast near the beginning of the run of iron from the cupola, this is followed by a medium grade of iron for miscellaneous castings capable of being machined readily, but not too soft to give good wearing service; this again is followed by strong iron mixtures intended for large and heavy work requiring metal of high tensile and transverse strength.

The importance of having some simple, cheap and reliable method of changing the physical properties of molten iron after it has been tapped from the cupola has been regarded as a desideratum ever since the value of the method of modifying the chilling property of car-wheel iron in individual ladles by treatment with powdered ferromanganese became well known. This led, as I have stated, to improper use of ferromanganese in ladles of foundry iron through ignorance of its proper functions.

As long ago as 1880 I made efforts in this direction with alloys of iron and silicon, but at that time the richest alloy obtainable contained less than 20 per cent silicon.

In later years, 50 per cent ferrosilicon was produced in electric furnaces for use in steel making, and these tests were then renewed with the results that have been already published, showing that the addition of a small quantity of the powdered 50 per cent ferrosilicon alloy in a ladle of molten foundry iron produces a remarkable effect upon it by softening and at the same time strengthening the iron. This is quite an opposite effect to that produced by increasing silicon in the cupola, which always tends to weaken iron.

The following table shows the results of a few tests of this kind made in 1905 with ordinary foundry irons (Table I):

The effect of adding 4 oz. of powdered 50 per cent ferrosilicon in a hand ladle holding about 25 lb. of molten iron, and of adding 1 lb. to 200 lb. of iron in a ladle, upon the strength and deflection, as compared with the same iron untreated, is clearly shown in this table. The success of these initial tests led to more extended investigations.

TABLE I.—RESULTS OF TESTS OF FERRO-SILICON IN LADLES

Date	Remarks per Cent Si	Breaking Strain (Lbs.)	Deflection (In.)	Resilience	Shrinkage (In.)	Per Cent Gain: Breaking Strain	Per Cent Gain: Deflection	Per Cent Gain: Resilience
Oct. 10, '05	¼ lb Hand	2265	.120	45.30	.192

FIG. 3.—EFFECT OF ADDING POWDERED FERROSILICON TO LADLE.

Fig. 3 shows the remarkable effect in reducing chill in foundry iron by adding thereto powdered 50 per cent ferrosilicon in different proportions in the ladle, ranging from three to eight-tenths of 1 per cent of silicon.*

No. 1 shows the fracture of two test bars cast from a ladle of untreated iron. The upper piece was cast in green sand, 1 in. x 1 in. x 15-in., and was an ordinary transverse test bar. The lower piece was cast in a heavy iron cup in order to very rapidly cool the metal. The upper test piece is perfectly gray and easy to drill. The lower one is perfectly white and cannot be drilled with an ordinary steel drill.

No. 2 shows the fracture of two similar test bars poured from the same iron after addition of 0.3 per cent of silicon in the form of high-grade ferrosilicon (50 per cent silicon) added in the ladle. Note the marked reduction in depth of chill in the sample cast in the iron cup.

No. 3 shows the fracture of two similar test pieces from the same iron after adding 0.5 per cent silicon in the ladle. The "chill" is still further reduced.

No. 4 shows the fracture of two similar bars from the same iron after adding 0.8 per cent silicon in the same manner. The chill in the sample cast in the iron cup is almost entirely absent.

The samples cast in sand are all perfectly gray, but there is an appreciable difference in the fracture, the treated metal showing softer iron than the untreated sample.

The metal selected for this particular test was comparatively low in silicon, consequently having com-

*"Iron absorbs silicon greedily, uniting with it in all proportions at least up to 30 per cent and apparently the more readily the higher the temperature, absorbing it even at a red heat when imbedded in sand and charcoal. It diminishes the power of iron to combine with carbon * * * thus favoring the formation of graphite during slow cooling. It increases the fusibility and fluidity of iron; it lessens the formation of blow holes; by reducing iron oxide it apparently removes one cause of red shortness; it hinders at high temperatures the oxidation of iron and probably of the elements combined with it."—The Metallurgy of Steel by Henry M. Howe.

paratively high chilling property, but this fact would never be suspected from an examination of the fracture of the test sample cast in sand. Very few practical founders are aware of the large variation in chilling property if their iron, sometimes of presumably similar grades, melted on different days, or even of the wide variations in different portions of one heat.

Here we have, I think, a practical solution of one great difficulty that has heretofore militated against the successful use of permanent iron molds for making castings that must be machined.

A mere "skin chill" not thicker than a piece of tissue paper makes the surface of a casting too hard to machine, but by this simple process the foundry foreman can eliminate the last trace of chill from his metal before pouring it into an iron mold.

For years past more or less encouraging efforts have been made and described in technical journals of methods for making castings in permanent iron molds.

The most ambitious one, perhaps, was the pipe casting process of Mr. Custer at Tacony, a few years ago, for which he obtained several patents. Mr. Custer ingeniously overcame the trouble from skin chill on his castings by turning them out of the molds before the molecules had taken a final set and the intense heat in the body of the casting helped to anneal out any skin chill that might have formed. Mr. Custer failed, unfortunately, to take into due consideration the fact that gray cast iron, of which his molds were made, "grows" or increases in cubical dimensions when repeatedly heated above a certain point and then cooled. This, I am informed, causes such a rapid deterioration of his casting machines that his process proved a failure and has been discontinued.

It will, no doubt, be a great surprise to you to learn that ever since the year 1888 machinable castings have been made in the foundry of Wm. Sellers & Co., Inc., in permanent iron molds and still are being so made. I am, through the courtesy of the president of that company, now permitted to show photographs made for this address of original iron molds, still in use, together with some machinable castings that were made in them years ago. Also large and small molds of more recent manufacture. In fact, more than a hundred permanent iron molds, ranging in weight from a few pounds up to 7000 lb. each, are to be found in use in this foundry.

The main object of casting in iron molds is to secure machinable castings of exceedingly fine grain, free from dirt, sponginess or other defects, while at the same time having marked increase in strength.

The question of relative cost of castings made in permanent iron molds (eliminating the molder entirely), as compared with similar castings made in green sand or in baked sand molds, depends upon the number of machinable castings required to be made from one pattern as well as upon other conditions.

In Fig. 4 is shown a picture of an all-iron mold made in 1903 for a saddle for 36-in. planing machine, also one of the gray iron machinable castings, absolutely free from any skin chill, made in this mold.

This was a difficult casting to obtain free from surface defects on one or the other face, or from draw holes, when made in sand, but when cast in this iron mold they were perfect, and all the saddles subsequently made, until a change was made in design, were cast in this iron mold.

This mold was made fifteen years after my first iron mold for machinable castings was made and used in the foundry of Wm. Sellers & Co., and twenty-three years after the first iron mold was made by me for casting "over-iron" in another foundry, and thereby hangs an amusing tale.

In the year 1880, I suggested to the foreman of the car wheel foundry of A. Whitney & Sons, Philadelphia, with which I had become connected as metallurgist, the idea of casting all the "over-iron" in iron molds instead of in open sand molds, thus giving more room on the foundry floor and avoiding expense of making up a sand pig bed daily.

The foreman exclaimed in alarm, "Why it will be all white iron and when we remelt it with the wheel mixture the next day the wheels will all be too hard. We do use a little white iron sometimes to bring up the chill when the mixture is running down in chill, but this plan would spoil all our calculations."

Nothing but an actual demonstration would convince the man of his error.

Iron pig molds were then ordered to be made and a ton of regular wheel iron cast therein. This iron was, of course, white. On the next day the ton of white iron was remelted in a small cupola without any admixture and cast into test bars, chill test pieces and two test wheels. On the following day, when all of these were broken, instead of being white iron, as the foreman had predicted, there was no appreciable difference found between the castings made from iron that had been chilled white in the iron molds and similar castings made from the same iron cast in sand molds. The result was that no sand pig bed was ever again made in that foundry as long as the works existed.

On coming to the establishment of Wm. Sellers & Co., Inc., in March, 1888, I found the same conditions and immediately substituted iron pig molds, which have been used daily ever since that time.

These iron molds for over-iron anticipated the machine-cast pig iron process now so generally used by many years and naturally led to the next step, namely, making permanent iron molds for castings, as soon as it was found practicable to prevent iron poured in

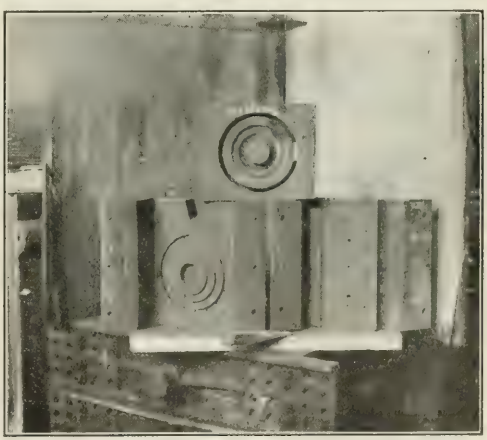

FIG. 4—IRON MOLD FOR SADDLE AND CASTING MADE IN THIS MOLD

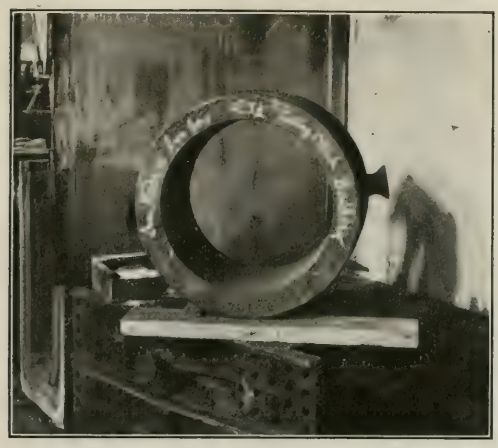

FIG. 5—IRON MOLD FOR LATHE BUSHING

FIG. 7—IRON MOLD AND CORE FOR SPIRAL PINION

them from being too hard to machine without trouble.

Fig. 4 shows an iron mold for "saddle" for 36-in. planing machine and casting made in this mold. The mold was made in 1903. This casting was a difficult one to make in a sand mold so as to get clean surfaces on both sides and free from draw holes. Fig. 5 shows an iron mold for bushing for 42-in. car-wheel lathe. This bushing is 19 in. in diameter, 13½ in. deep and only 1-in. thick. The mold is 6½-in. thick, and there is a collapsible iron core. The metal must be absolutely free from chill as the thin casting is turned inside and outside. Fig. 6 shows an iron mold for friction disks for dynamometer for Pennsylvania Railroad, 42 in. in diameter, cast 1½ in. thick, finished all over ⅞ in. thick. The pull on the draw bar of the locomotive on this machine was originally 80,000 lb., afterward increased to 100,000 lb. It was essential that these cast-iron disks should be fine grained and free from the slightest defects. After failing to procure satisfactory castings in sand molds they were cast in this iron mold and were perfect disks. The casting is poured from bottom. Fig. 7 shows an iron mold and iron core for

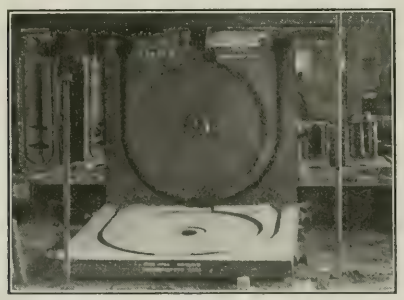

FIG. 6—IRON MOLD FOR FRICTION DISKS

spiral pinion for 36-in. planing machine. Five teeth 2 in. deep are cut from solid metal. "Semi-steel" is cast in this mold, free from chill, and poured from the bottom. Fig. 8 shows an iron mold for "over-pig." The molds were first made in 1880, and this mold has been in constant daily use for many years. On top of mold are two iron molds for "lifting nuts" from cross-head of large boring mills from 10 to 16 ft. These castings must be made of very strong, fine grained iron. Also on top are two test bars originally of the same size, viz., 14 13/16-in. x 1-in. x 1-in. cast in the same mold from one ladle of iron. One bar has been caused to "grow" or increase in size to 16½-in. x 1⅛-in. x 1⅛-in., equivalent to 40 98/100 per cent enlargement.

Anticipating the question, "How do you prevent these molds from warping or growing so as to become useless?" I will say there are two distinct methods. The simplest method and the one we adopt is to make but one casting from one melt in one iron mold. In this way the mold never gets red hot so that it does not grow. The second method is to use low silicon iron for the molds, as metal of that character grows far less when repeatedly heated and cooled above a cherry red

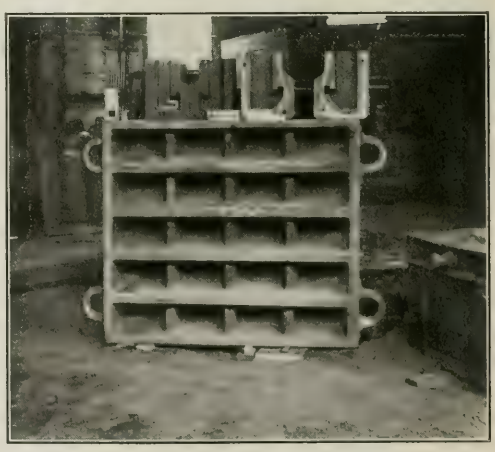

FIG. 8—IRON MOLD FOR OVER-PIG

than does soft foundry iron. Finally, I may say that castings made of white iron do not expand permanently when heated and cooled sufficiently to overcome the original shrinkage of the metal, so that when practicable, permanent iron molds may be made of white iron.

Cutting Oils

Their Properties, Composition, Examination and Industrial Application

By C. W. Copeland

Chief Chemist Remington Arms Company of Delaware..

The industrial chemist is frequently called upon to make an examination of compounded oils which, for want of a better name, are known as cutting oils. While these oils are not exactly new, the literature pertaining to them is rather vague and indefinite. In fact there seems to be a decided lack of literature on the subject and in view of the great importance of these oils to the modern metal cutting industries and considering the large sums expended annually for them, the subject is undoubtedly worthy of the fullest investigation.

It is the writer's intention, in the present article, to give a general résumé of the composition, properties and industrial use of these compounded oils, coupled with concise directions for examining them, so that the chemist may thereby form an intelligent opinion of their worth. In this manner, by making a preliminary examination of such oils in the laboratory, the chemist can eliminate much worthless and unsuitable material and greatly assist a plant engineer or the purchasing department in deciding upon the oils best fitted for each particular purpose. Furthermore, all oils that are found to be especially effective for each specific purpose can be kept up to the same standard by frequent analysis; specifications can be devised and adhered to, and much time, annoyance and expense can be saved, instead of proceeding with time-consuming and frequently haphazard shop testing of oils purchased at random.

The usual physical tests, as applied to lubricating and other purely mineral oils, are not of much service in examining oils of this character, nor are the standard methods for determining the chemical constants of animal and vegetable oils and fats applicable, but rather a combination of both.

The literature pertaining to mineral oils and their derivatives and to other oils, fats and waxes is extensive, and, as it is not within the scope of this article to treat of these in detail, the reader is referred to standard works on the subject for more complete information.

As compounded oils, however, are composed of these two widely different classes of oils, a brief description of their general characteristics follows:

Commercial mineral oils are derived from the different fractional distillations of crude petroleum. They are simple hydrocarbon oils which do not contain any organic fatty acids and are therefore not affected by any of the ordinary saponification agents. They are not true definite compounds in a chemical sense, their composition depending entirely upon their source and the temperature at which each fraction is distilled.

Animal and vegetable oils, on the other hand, exhibit certain well defined chemical characteristics which are uniform, within certain limits, for each particular oil. Olive oil, for instance, has certain chemical constants which vary but little, no matter how widely separated are the sources from which it is derived, and this is especially true of pure oil, consequently its purity and composition can be definitely ascertained by chemical means.

These oils are rather complex substances formed from glycerol and organic fatty acids, technically known as triglycerides, and natural oils and fats are mixed triglycerides containing one or more different fatty acids. All triglycerides are broken up and decomposed by heating them with caustic alkalies, undergoing saponification or hydrolysis with the formation of the alkaline salts of the fatty acids, and glycerol. These alkaline salts are commonly known as soaps and it is due to this phenomenon that analysis and separations of mixed mineral, animal and vegetable oils can be made, by varying the menstruum in which they are soluble and by various other means.

In the following treatment of the subject an attempt has been made to present it mainly from a chemical viewpoint, the details of application being left to the more experienced shop engineers.

Numerous examples of analyses are given to assist the chemist in interpreting his results.

The writer begs indulgence for this verbose introduction and hopes to provoke a discussion of this highly important subject which has been very much neglected.

STRAIGHT CUTTING OILS

For the metal cutting and stamping industries, certain simple and compounded oils are required and the function of these so-called cutting oils is to furnish lubrication to the point or surface of the cutting tool and also to conduct away the large amount of heat generated, so that the tool will not become overheated and the temper drawn. Of course, with the modern high-speed tool steels, this heating of the tool itself has not the serious effects as on a plain carbon tool steel, but as cutting oils in general greatly improve the quality of the work, making smoother and speedier cuts and at the same time greatly prolonging the life of the tool; they are almost universally used in drilling, boring, reaming, milling and various other operations.

A great variety of oils and cutting compounds are manufactured and used for this purpose and they may be roughly subdivided into two general classes, *straight* cutting oils and *soluble* cutting oils.

The straight cutting oils are used directly on the machines without any further treatment and are intended mainly for the more delicate lathe work and fine boring and reaming operations and also for operations on high-carbon, special-alloy steels and other metals, in cases where the hardness or other physical properties of these metals require special treatment.

These oils consist of either lard oil, sperm oil, or vegetable oils or a mixture of one or more of these oils with certain mineral oils. Pure lard oil or a mixture of lard and mineral oil are the most extensively used members of this class. Pure mineral oil can also be used as a straight cutting oil but only to a limited extent.

Pure lard oil is pre-eminently the ideal straight cutting oil for all classes of work excepting that in which the amount of heat generated by the cut is high, thus making the cooling action of the lubricant very important. It seems to have the property of adhering tenaciously to the point or surface of the cutting tool even under the influence of moderate heat, a property that is not possessed by many other oils having a much higher viscosity. Under certain conditions and for special

purposes, where other simple and compounded oils fail, lard oil will generally prove effective.

Lard oil to be efficient, however, should be of the best quality, as the poorer grades contain considerable amounts of free fatty acids which tend to cause corrosion of brass, copper and other metals and to damage the bearings and other parts of the machines. An excessive amount of free fatty acid will also cause the oil to be foul smelling and will gum the machines.

The extensive use of lard oil as a cutting medium is limited, however, due mainly to its high cost, which is over one dollar per gallon at present* although it has been as low as 60 cents per gallon. This high cost has led to the introduction and substitution of mixtures of lard oil with petroleum oils and to the limited application of mineral and other inexpensive oils on certain classes of work where such substitutes would give satisfactory results.

These oils are now extensively manufactured and are known as mineralized lard oil, lardoleum and by various other trade names.

For straight cutting work, an oil must possess a moderately high viscosity, excellent heat conductivity, a high flash and fire test and a fairly low cold test. It should be free running, non-corrosive and must not thicken or gum in use. It should be compounded from good neutral mineral oils, possessing in general the qualifications of lard oil, and a good grade of lard oil containing a minimum of free fatty acid, not over 5 per cent at the most. The compounded oil should be a homogeneous mixture that must not segregate into its various components upon standing. Rancid oils should not be considered in an oil of this character, especially when masked by phenolic or other disinfectants, on account of the injurious effects it would have on the hands and persons of the workmen.

As a general rule the efficiency of these oils is governed by the amount of lard oil they contain, and the price is usually fixed by the same factor.

As lard oils and vegetable oils are saponifiable oils, and as mineral oils are non-saponifiable oils, it is evident that if a compounded oil be made from pure materials we have a ready means of evaluating them by simply determining the amount of saponifiable matter they contain. Also a determination of the acidity of the oil, coupled with the usual physical oil tests, would give a further indication of its value. Oils made from inferior materials can be separated by saponification processes and the inferior oils can then generally be positively identified.

Adulteration and substitution of the more expensive oils is sometimes practiced in the manufacture of cutting oils. For instance, lard oil is sometimes adulterated with cottonseed, rosin and various other oils. While cutting oils compounded from these various oils would be perfectly satisfactory for certain purposes, the purchaser does not wish to pay high prices for them expecting to get lard oil; consequently their detection becomes an important matter.

SOLUBLE CUTTING OILS

The soluble cutting oils are divided into many classes, but all depend upon the property of forming a milky emulsion when mixed with water. These oils are made and used primarily for heat conduction in heavy cutting, drilling, milling, stamping and other operations and at the same time they furnish considerable lubrication at the cutting points and surfaces. A saturated water solution of sal-soda was originally employed for this cooling purpose, but as it was devoid of lubricating properties, it has been largely replaced by soluble oil compounds.

These oils are usually compounded from mineral oils mixed with a specially treated animal or vegetable oil such as lard, cottonseed, corn, rapeseed, castor, olive rosin, neatsfoot and various other oils. They are known as sulphonated, phenolated and soap oils.

The *sulphonated oils* are made by treating castor oil with concentrated sulphuric acid, thereby forming a sulpho-compound with the ricinoleic acid of the oil. This treatment with sulphuric acid is proceeded with until a portion of the oil is found to be soluble in water. The mixture is then treated with common salt and the excess of acid is then neutralized with ammonia or other alkali. This base is then mixed with the proper proportion of mineral oil, sufficient care being taken to add enough of the base to hold all of the oil in an emulsion when the water is added. Turkey-red oil is an example of this class of oils and while castor oil is generally used, forming a true sulpho-compound, other oils such as cottonseed, olive, etc., may be substituted. These oils usually have an acid reaction toward phenolphthalein, and unless care is used in their manufacture they are liable to cause trouble by containing free sulphuric acid which would cause serious corrosion.

Soap oils (soluble oils containing soap) are compounded from mineral oils and a saponifiable oil, either animal or vegetable. Part or all of the animal or vegetable oil is saponified with an alkali, forming a soap, and the product is then added to the mineral oil in the proper proportions so that when it is diluted with water a creamy emulsion is formed, the soap acting as a carrier for the mineral oil and the unsaponified fat, holding these oils in suspension in the water. The free fatty acids, usually oleic or resin acids, are generally used for making the soap, being cheaper; this is then mixed with the neutral oil, the mineral oil and the other ingredients. Alcohol is sometimes added to effect a more ready solution of the soap and to keep the compounded oil clear. In this class of oils an excessive amount of soap should be avoided or gumming is liable to result. Amounts up to 15 per cent are permissible, but if they are properly manufactured less than 10 per cent seems to be quite sufficient.

The *phenolated oils* are similar to the soap oils in composition, being compounded from carbolic acid and an alkali. The phenolic odor of such oils suggests a disinfectant and is sometimes used to mask the odor of rancid fats. However, if these oils are properly made, this odor is not objectionable and is not detrimental.

Most of the soluble oils are of the above general classes and are manufactured under various trade names, the details of manufacture generally being kept secret by the makers. The subsequent analyses, made of various kinds of these soluble oils, will give an excellent idea of their general composition.

A first-class soluble oil should be a homogeneous mixture that should not segregate into its various components upon standing; it should form a perfect emulsion with water with the minimum separation of mineral oil. To give the best results soluble oils should be carefully

*When this was written (6-24-17) prime lard oil was $1.80 per gal.

made from high-grade materials, otherwise they are likely to cause trouble by rusting the machines and work, being corrosive and gumming the slides and other moving parts of the machines.

With soluble oils no hard and fast rules can be laid down for their evaluation. The total saponifiable matter, the percentage of free fatty acids, the neutral oil as fat and the amount of soap present are important considerations. Of decided importance is the stability of the emulsion formed with water at the various dilutions, as separation of the oil and water may cause damage to the tools, work or machines, besides losing the lubricating value of the compound. The amount of water and volatile matter present should also be considered, likewise any propensity toward gumming. The usual physical tests are not of much service in examining these oils, as they are never used in their original condition.

The intelligence and skill used in the manufacture of these oils is an important factor, as some oils containing a minimum amount of saponifiable matter, soap, etc., may be perfectly satisfactory, while conversely, an oil showing a relatively high percentage of these same constituents may be worthless, due to the lack of knowledge on the part of the manufacturer. As with straight cutting oils, no oil of this character should be considered that has been compounded from rancid and inferior animal or vegetable fats, the odor of which is usually masked by phenolic or other disinfectants.

Regarding the actual application of the various kinds of cutting oils and compounds, their use should be governed entirely by the conditions and the kind of work which they may be called upon to perform, and the treatment herein given, applying to this branch, has been more or less of a general nature.

For detailed information regarding the application, distribution, costs and other data concerning these oils, the reader is referred to a most complete and excellent article by Edward K. Hammond.[1]

Methods of Analysis

Two general methods were devised for the analysis of compounded oils, designated as A and B. Method A is a gravimetric separation of the saponifiable matter and the mineral oil and is useful as a check method and also where a further examination of the separated oils is contemplated, to determine their origin, nature and characteristics. Method B is a volumetric method and gives more complete information as to the condition of the saponifiable matter; it is also much more rapid. Both methods can be applied to the two classes of oils without any changes.

In the following methods, all flasks and other containers used for weighing samples and residues should be first thoroughly cleaned, rinsed with distilled water, alcohol, ether and then dried in an oven for one hour at a temperature of 100 deg. to 105 deg. C.

Preparation of Sample.—Mix the oil thoroughly by vigorously shaking the container, or, if in a barrel, by rolling it on the bilge; then fill two 4-ounce oil sample bottles with the well-mixed oil and label properly. Use one sample for the general analysis and place the other sample where it will not be disturbed for use later in the segregation test.

[1] *Machinery*, January, 1917.

Before commencing the analysis, the color, odor, turbidity and any other characteristics of the original oil should be noted.

Method A—Determination of Saponifiable Oil and Mineral Oil

Weigh 4 to 6 grams of the thoroughly mixed oil in a 300-cc Erlenmeyer flask, add 50 cc of the alcoholic potash (40 grams of potassium hydroxide dissolved in one liter of alcohol that has been redistilled after standing for some time over potassium hydroxide), and then boil the mixture under a reflux condenser for from one to two hours. An oil or water bath maintained at about 100° C., or an electric hot plate is suitable for boiling the liquid.

Disconnect the apparatus and boil off most of the alcohol, being careful not to overheat the oil or decomposition may result. Add about 50 cc of hot water to the residue in the flask, agitate and transfer to a 500-cc separatory funnel and wash out the contents of the flask with small successive portions of hot water, keeping the total volume in the funnel under 150 c.c. Cool the solution in running water and when cold add 75 cc of ether, stopper the funnel and shake vigorously. Allow the two layers to separate for about 12 hours or over night. If, after standing for some time, the solution does not show a tendency to separate into two distinct layers, the separation may be accelerated by adding a little alcohol, about 2 cc at a time, and shaking after each addition, which will usually effect a complete separation. The upper layer contains the ethereal solution of the unaffected mineral oil and the lower layer contains the animal or vegetable oil which has been converted into water soluble soap by saponification with the alcoholic potash.

Run the lower layer into another separatory funnel and wash the ethereal solution with about 50 cc of cold water, allowing the water to run down the sides of the funnel while rotating the same; allow to clear and then run the wash water into the second funnel. Add dilute sulphuric acid, containing about 5 cc of concentrated acid, to the soap solution in the second funnel to liberate the fatty acids. Cool in running water and when cold add 75 cc of ether, stopper the funnel and shake vigorously, allow to separate for about one-half hour or until clear and then run off the lower aqueous layer which is discarded.

Wash the ethereal solution of the fatty acids with about 50 cc. of cold water, allowing the water to run down the sides of the funnel while rotating the same; allow to clear, run off and repeat the washing with cold water until the wash water is no longer acid to blue litmus paper; about two washings will suffice.

Saponifiable Oil.—Drain off the wash water entirely from the ether solution of the fatty acids and then run the ethereal solution into a weighed 150-c.c. Erlenmeyer flask and rinse out the funnel with a small amount of ether. Cautiously evaporate off the ether and then heat the flask for one hour in a drying oven at a temperature of 100 to 105 deg. C., cool and weigh as saponifiable matter. The saponifiable matter in this case consists of the hydrates of the fatty acids. If any water is carried over into the ether solution, it may be removed when heating the residue, by spreading the oil in a thin layer over the interior of the flask; any water

present is then more easily volatilized without causing the oil to spurt.

Mineral Oil.—Drain off the wash water entirely from the ethereal solution of the mineral oil in the first funnel and then run the ethereal solution into a weighed 150-c.c. Erlenmeyer flask and rinse out the funnel with a small amount of ether. Proceed with the evaporation, heating, etc., exactly as directed for the determination of the saponifiable oil, finally weighing the product as mineral oil.

Method B—Determination of Total Saponifiable Matter and Total Fatty Acids

Weigh 4 to 6 grams of the oil in a 300-c.c. Erlenmeyer flask, add 50 c.c. of the alcoholic potash solution and boil the mixture under a reflux condenser for from one to two hours. Disconnect the apparatus, boil off most of the alcohol, add about 50 c.c. of hot water to the residue, agitate and transfer to a 500-c.c. separatory funnel and wash out the flask with small successive portions of hot water. Add dilute sulphuric acid, containing about 5 c.c. of concentrated acid, to the solution in the funnel and cool in running water; when cold add 75 c.c. of ether, stopper and shake vigorously. Allow the two layers to separate for about one-half hour or longer if necessary; when clear, run off the lower aqueous layer and discard. Wash the ethereal solution with about 50 c.c. of cold water, allowing the water to run down the sides of the funnel while rotating the same, being careful not to disturb the ethereal layer too much, as troublesome emulsions are liable to be formed. Allow to stand until clear, run off the wash water, discard and repeat the washing with cold water until the wash water is free from acid when tested with blue litmus paper, about two washings will suffice. Drain the ethereal solution into the original flask, which has been rinsed with a little alcohol and allowed to drain, and wash out the funnel with a small amount of ether. Cautiously evaporate the solution in the flask until most of the ether has been driven off.

Neutralize 50 c.c. of alcohol with tenth-normal alkali, using 20 drops of a 1 per cent solution of phenolphthalein as an indicator. Add the neutral alcohol to the contents of the flask, heat to boiling and titrate with the tenth-normal alkali until the pink color persists after vigorous shaking. The flask should be stoppered and shaken vigorously toward the end of the titration.

Total Saponifiable Matter.—Multiply the number of cubic centimeters of tenth-normal alkali used in this titration by 0.028773 and divide by the weight of the sample taken, to obtain the total saponifiable matter in one gram of the oil.

In this titration it is assumed that one gram of the saponifiable matter requires 195 milligrams of potassium hydroxide for its saturation, i.e. it has a saponification value of 195. One cubic centimeter of tenth-normal alkali is equivalent to 0.0056108 grams of potassium hydroxide, consequently

$$\frac{0.0056108}{0.195} = 0.028773.$$

This factor is accurate for most of the oils entering into this class of compounds; exceptions will be noted later.

Total Fatty Acids.—Multiply the number of cubic centimeters of tenth-normal alkali used in this titration by 0.0282 and divide by the weight of the sample taken, to obtain the total fatty acids in one gram of the oil.

The above factor is based on the assumption that the fatty acids exist as oleic or some similar acid, which is a very close approximation of the truth; exceptions will be noted later.

DETERMINATION OF FREE FATTY ACIDS

Weigh 5 to 10 grams of the oil in a 300-c.c. Erlenmeyer flask. Neutralize 50 c.c. of alcohol with tenth-normal alkali, using 20 drops of phenolphthalein as an indicator. Add the neutral alcohol to the contents of the flask, heat to boiling and titrate with the tenth-normal alkali until the pink color persists after vigorous shaking. The flask should be stoppered and vigorously shaken toward the end of the titration.

Free Fatty Acids.—Multiply the number of cubic centimeters of tenth-normal alkali used in this titration by 0.0282 and divide by the weight of the sample taken, to obtain the free fatty acids, as oleic acid, in one gram of the oil.

DETERMINATION OF SOAP, FATTY ACIDS COMBINED AS SOAP, FATTY ACIDS COMBINED AS FAT AND NEUTRAL OIL

Weigh 4 to 6 grams of the oil in a 300-c.c. Erlenmeyer flask, add about 50 c.c. of hot water, agitate, transfer to a 500-c.c. separatory funnel and wash out the flask with small successive portions of hot water. Add dilute sulphuric acid, containing about 5 c.c. of concentrated acid, to the solution in the funnel and cool in running water. When cold, add 75 c.c. of ether, stopper the funnel and shake vigorously. Allow the two layers to separate for about one-half hour or longer if necessary; when clear, run off the lower aqueous layer and discard. Wash the ethereal layer with about 50 c.c. of cold water, allowing the water to run down the sides of the funnel while rotating the same. Allow to stand until clear, run off the wash water and repeat the washing with cold water until the wash water is no longer acid when tested with blue litmus paper; about two washings will suffice. Run the ethereal solution into the original flask, which has been previously rinsed with a little alcohol and allowed to drain and carefully evaporate off most of the ether.

Neutralize 50 c.c. of alcohol with tenth-normal alkali, using 20 drops of phenolphthalein as an indicator. Add the neutral alcohol to the contents of the flask, heat to boiling and titrate with the tenth-normal alkali until the pink color persists after vigorous shaking of the stoppered flask.

Fatty Acids as Soap.—Multiply the number of cubic centimeters of tenth-normal alkali used in this titration by 0.0282 and divide by the weight of the sample taken and call the result (*a*). Subtract from this result the free fatty acids, per gram of oil, as found in a previous determination, and the remainder is the fatty acids combined as soap in one gram of the oil.

Soap.—Multiply the result obtained for the fatty acids combined as soap by 1.078; the product is the sodium soap formed by the alkali and these acids.

Sodium soap (sodium oleate), mol. weight.

$$\frac{304}{282} = 1.078.$$

Fatty acids (oleic acid), mol. weight

$$\frac{304}{282} = 1.078.$$

If a potassium soap is required, substitute the factor 1.13 in the above calculation.

Fatty Acids as Fat.—Subtract the result (*a*) from the total fatty acids found in a previous determination, to obtain the fatty acids combined as fat in 1 gram of the oil.

Neutral Fatty Oil.—Subtract the result (*a*) from the total saponifiable matter found in a previous determination, to obtain the neutral fatty oil in 1 gram of the sample.

NOTES

All of the determinations in the foregoing methods of analysis are applicable and useful in the examination of soluble cutting oils, but as straight cutting oils obviously do not contain soap nor fatty acids as soap, these determinations are omitted. There are actually only three determinations in method B, the other information being obtained by simple calculations. Much time can be saved if the titrations are all performed at one time and several oils can be analyzed successively, leaving the titrations to the last. The end point in these titrations is usually very sharp, but if any trouble is experienced in accurately determining this point with dark-colored oils, by titrating back with tenth-normal hydrochloric acid, the change can be rendered very distinct so that one or two drops of either standard solution will give the color reaction. It is advisable to follow this procedure in all of the titrations, as very concordant results can then be obtained and over-titrations avoided.

As method A gravimetrically determines only the hydrates of the fatty acids that exist in the oil, the results by this method will be a trifle low for oils where these fatty acids were originally present as neutral fatty oil, due to the loss of the glycerol radicle. This loss is somewhat compensated for, due to the fact that the fatty acids are weighed as hydrates and not as anhydrides.

In method B the total saponifiable matter is based on the assumption that the oil has a saponification value of 195, which is correct for most of the oils entering into this class of compounds. Sulphonated oils, however, usually contain a castor oil base which has a saponification value of about 184, consequently

$$\frac{0.0056108}{0.184} = 0.0305.$$

This factor would be the proper one to use when castor oil is required and 0.02983 would be the correct factor for the ricinoleic acid of this oil.

PHYSICAL TESTS

Emulsification Test.—Prepare an emulsion of the soluble oil by mixing a measured portion of the oil with the required amount of water, place in a 4-ounce oil sample bottle and set aside for further observation. One part of oil to ten or twenty parts of water is sufficient for test purposes, but any other required volume of water may be used. The character of the emulsion should be noted while preparing the same and again examined after standing undisturbed for 24 hours.

Segregation Test.—After standing for at least 24 hours, weigh out a portion of the oil which was placed aside for the segregation test, by pouring from the upper surface without disturbing the rest of the oil. Make a determination of the free fatty acids or the total saponifiable matter on this sample. Any difference in this determination from the one made with the well-mixed sample is proof of the segregation of the oil into its various components; this segregation increasing, of course, the longer the oil is allowed to stand undisturbed until it reaches a maximum.

Evaporation Test.—Weigh 1 to 2 grams of the oil in a weighed Petri dish or in a shallow flat aluminium dish about 50 to 75 mm. in diameter. Place in a drying oven and heat at a temperature of 100 to 105 deg. C. for about 3 hours, cool and weigh. Replace in the oven for 30 minutes, cool, weigh and repeat the operation until a fairly constant weight is obtained. The loss in weight divided by the weight of the sample taken is the water, alcohol and any other volatile matter in 1 gram of the oil. The residue should then be examined to see if it shows any tendency toward gumming.

Compounded oils that contain light mineral oils will require heating over long periods, as considerable portions of this light oil will volatilize at this temperature.

To determine the amount of volatile mineral oil, first ascertain the temperature at which the oil will flash when it is heated in an open cup tester and then proceed as follows: Weigh out a portion of the mineral oil, which has been separated by method A, into the evaporating dish, as directed above. There seems to be very little loss of mineral oil when it is dried in the flask as directed in method A, which is probably due to the shape of the flask.

Place the dish containing the oil in the drying oven and heat at a few degrees below the flashing temperature until the weight is fairly constant. The loss in weight divided by the weight of the oil taken will give the amount of mineral oil volatile at this temperature, and this result divided by the percentage of total mineral oil will give the percentage of volatile mineral oil.

Physical Oil Tests.—The usual physical oil tests are too well known to require more than a brief mention here.

Determine the specific gravity with a Westphal balance or with an accurately calibrated hydrometer. The hydrometer is usually used and is much more rapid.

Determine the flash and fire test in an open cup tester of the Cleveland type.

The viscosity should be determined at 100 deg. Fahr. with a Saybolt viscosimeter. If the oil is too viscous to determine its viscosity at this temperature, a higher temperature may be employed. Most cutting oils, however, will move freely at 100 deg. Fahr., and as the results are only comparative this or some other uniform temperature should always be employed.

For the cold and cloud tests, any standard or suitably assembled apparatus may be used, the temperature being varied, of course, to suit the requirements of the oil being tested.

The above tests apply mainly to straight cutting oils.

Analyses of Soluble Cutting Oils

Following is an analysis of a soluble cutting oil and the results shown demonstrate the agreement and uni-

Oil No. 1

Test No.	Total saponifiable matter	Total fatty acids	Free fatty acids	Fatty acids as fat	Fatty acids as soap	Soap	Neutral fatty oil	Mineral oil
Method A—								
1	18.96	...	...	...	...	...	...	72.14
2	18.83	...	...	...	...	...	...	72.02
3	18.67	...	...	...	...	...	...	72.20
Average	18.82	...	...	...	...	...	...	72.12
Method B—								
1	18.81	18.44	6.25	0.98	11.21	12.12	1.35	...
2	18.71	18.34	6.21	0.98	11.15	12.05	1.35	...
3	18.65	18.28	6.13	0.98	11.17	12.07	1.35	...
Average	18.72	18.35	6.20	0.98	11.18	12.08	1.35	...

Water and volatile matter, 8.26 per cent.

formity that may ordinarily be expected in an analysis by the foregoing methods.

In its original condition this oil is a cloudy, reddish, viscous liquid, possessing a slight alcoholic odor and undergoing oxidation if left exposed to the air, a thick scum being formed on the surface. This oil is evidently a soap oil, as shown by the moderately large amount of soap present, and furthermore, that this oil was compounded from fatty acids is shown by the large amount of free fatty acid and the small amount of neutral fatty oil found; of the 18.72 per cent of total saponifiable matter, 17.38 per cent was present in the original oil as fatty acid and 1.35 per cent as neutral fatty oil. The fatty acid used was evidently oleic acid.

After standing for different periods the original oil showed a decided tendency to segregate, the total saponifiable matter varying from 6 to 20 per cent, the soap evidently precipitating and settling to the bottom of the container.

The 1 to 10 and 1 to 20 water emulsion, prepared with either warm or cold water and the well-mixed oil, is fair, emulsion is cream colored, foaming slightly when agitated; after 24 hours had a slight curd on the surface and a slight separation of mineral oil. The emulsion prepared from the oil after standing, without mixing thoroughly, is very poor, a large proportion of the mineral oil separating immediately.

This oil could not be recommended except in cases where a low price might prove a consideration, as its segregating and oxidizing properties would require special care and precaution in mixing. The price of this oil is about 50 cents per gallon, consequently the above objections would practically eliminate it, as much better oils can be obtained for the same price.

The general composition of this oil would be about as follows:

Mineral oil	72.12%
Free fatty acid	6.20%
Soap	12.08%
Neutral fatty oil	1.35%
Water and volatile matter	8.26%
Total	100.01%

Oil No. 2

	Method A	Method B	Castor Oil Base
Total saponifiable matter	12.86%	12.12%	12.92%
Total fatty acids		11.86%	12.56%
Free fatty acids		11.43%	12.08%
Fatty acids as fat		0.17%	0.21%
Fatty acids as soap		0.25%	....
Soap		0.28%	....
Neutral fatty oil		0.44%	0.62%
Mineral oil	77.57%	....	....
Total volatile matter			25.35%
Volatile mineral oil			18.30%
Water, ammonia, alcohol, etc			7.05%

The above is an analysis of a soluble oil which was clear, wine-red and rather fluid in its original condition and possessed a strong odor of ammonia and kerosene or some similar volatile mineral oil. The presence of ammonia was shown by the vapor from the oil causing red litmus paper to turn blue. The original oil flashed at 150 deg. Fahr. and burned at 160 deg. Fahr. in an open cup tester, showing conclusively the presence of light mineral oils, kerosene or gasoline, which were present to the extent of 18.30 per cent, as shown by an evaporation test.

The reaction of the oil toward phenolphthalein was acid, notwithstanding the ammonia which was present which does not affect this indicator; this acid reaction was due to the organic acids present.

That this oil is evidently a sulphonated oil is shown by the absence of soap and by the large amount of free fatty acids present; the saponifiable matter in such an oil would be largely in the form of sulpho-acids.

This oil was analyzed by methods A and B; method A determines the total fatty acids gravimetrically; method B is evidently too low based on the assumption that the saponifiable matter is lard oil or some similar oil with a saponification value of 195. Sulphonated oils are usually made from castor oil which has a saponification value of about 184, consequently basing our calculations on this value and figuring the fatty acids as ricinoleic acid, we get the results as tabulated under castor oil base; the results for the total saponifiable matter by both methods then agree closely.

This oil showed but very slight tendency to segregate in its original condition and it does not oxidize or thicken on exposure to the air. The slight segregation consists in forcing more of the sulpho-base to the surface of the oil.

The 1 to 10 and 1 to 20 emulsions formed with cool water were excellent, foaming slightly in preparation; after standing for 24 hours showed a slight curd on the surface and a slight separation of mineral oil. Hot water should not be used, as it causes a decided separation of mineral oil.

The above oil can be recommended for excellent emulsification, freedom from oxidation, thickening, gumming; for non-segregation and freedom from mineral acids and other corrosive agents. The main objection is the presence of considerable volatile mineral oil, which would constitute a fire hazard if the oil be left exposed before using; this objection, however, does not apply to any great extent after the oil has been emulsified. The price is 48 cents per gallon.

The general composition of this oil would be about as follows:

Non-volatile mineral oil	59.27%
Volatile mineral oil	18.30%
Fatty sulpho-acids	15.34%
Neutral fatty oil	0.62%
Water, ammonia and other volatiles	7.05%
Total	100.58%

Oil No. 3

	Method A	Method B
Total saponifiable matter	15.30%	15.57%
Total fatty acids		15.25%
Free fatty acids		0.13%
Fatty acids as fat		5.47%
Fatty acids as soap		9.65%
Soap		10.40%
Neutral fatty oil		5.80%
Mineral oil	75.50%	....
Total saponifiable matter after standing (segregation)		8.58%
Total saponifiable matter of the well mixed oil (segregation)		15.57%
Water, alcohol, etc		8.40%

The above is an analysis of a soluble oil which was a

clear, brown-red fluid oil in its original condition with a slight alcoholic phenol odor.

That this oil is evidently a soap oil is shown by the presence of considerable soap and that it was compounded from good neutral oils is shown by the trifling amount of free fatty acids present.

In its original condition this oil showed a decided tendency to segregate upon standing and this segregation consisted in the settling out of the soap, forcing the volatile matter and mineral oil to the surface.

The 1 to 10 and 1 to 20 emulsions formed with cool water were very poor, the mineral oil separating almost immediately; after standing for 24 hours there was a large separation of mineral oil. The same result was obtained by using warm water for the emulsion.

The above oil could not be recommended because of its segregation and for its poor emulsification qualities. The price is 48 cents per gallon.

This oil is an example of good materials being compounded into a poor soluble oil by lack of skill and knowledge on the part of the manufacturer; the defect in this case being possibly an insufficiency of soap to carry all of the particular mineral oil in suspension when it is diluted with water.

The general composition of this oil would be about as follows:

Mineral oil	75.50%
Neutral fatty oil	5.80%
Soap	10.40%
Free fatty acids	0.13%
Water, alcohol, etc.	8.40%
Total	100.23%

Oil No. 4

	Method A	Method B
Total saponifiable matter	17.06%	16.37%
Total fatty acids		16.05%
Free fatty acids		4.68%
Fatty acids as fat		3.71%
Fatty acids as soap		7.66%
Soap		8.26%
Neutral fatty oil		4.03%
Mineral oil	76.26%	

Water, alcohol, etc., 7.00%. Segregation, none.

The above is an analysis of a soluble oil which, in its original condition, is a clear, dark-red, fluid oil possessing a slight odor of alcohol and a deep blue bloom or fluorescence.

This oil is a soap oil which does not oxidize or thicken on exposure to the air; an evaporation test showed no gummy residue, and the oil does not segregate upon standing.

The 1 to 10 and 1 to 20 emulsions formed with warm or cold water were excellent white emulsions, foaming slightly in preparation; after 24 hours there was no separation of mineral oil and no formation of curd.

This oil could be highly recommended for its non-segregation, freedom from thickening, oxidizing, gumming and for perfect emulsifying qualities. The price is 45 cents per gallon.

This oil is an example of what would constitute a nearly perfect oil which has been compounded properly and at the same time containing only a moderate amount of soap and saponifiable matter.

The general composition of this oil would be represented by the following:

Mineral oil	76.26%
Neutral fatty oil	4.03%
Free fatty acids	4.68%
Soap	8.26%
Water, alcohol, etc.	7.00%
Total	100.23%

Oil No. 5

	Method A	Method B	Castor Oil Base
Total saponifiable matter	18.24%	17.21%	18.29%
Total fatty acids		16.86%	17.82%
Free fatty acids		14.80%	15.65%
Fatty acids as fat		1.62%	1.70%
Neutral fatty oil		1.97%	2.17%
Mineral oil	75.22%		
Total volatile matter			17.37%
Volatile mineral oil (segregation very slight)			14.07%
Water, ammonia, etc.			3.30%

The above is an analysis of a soluble oil which, in its original condition, was a clear, wine-red, fluid oil possessing a strong odor of ammonia and a deep fluorescence or bloom. This oil contained considerable quantities of volatile mineral oils, the original oil flashing at 135 deg. Fahr. and burning at 145 deg. Fahr.

An inspection of the analysis shows this oil is a sulphonated oil and it possesses in general the characteristics of Oil No. 2 regarding segregation, emulsification, oxidation, thickening, gumming and freedom from corrosive acids.

It can be recommended, with reservations as to fire hazard, the same as the preceding oil. The price is 44 cents per gallon.

The general composition of this oil would be about as follows:

Non-volatile mineral oil	61.15%
Volatile mineral oil	14.07%
Fatty sulpho-acids	19.87%
Neutral fatty oil	2.17%
Water, ammonia, etc.	3.30%
Total	100.56%

Oil No. 6

	Method A	Method B
Total saponifiable matter	22.00%	21.71%
Total fatty acids		21.30%
Free fatty acids		5.08%
Fatty acids as fat		8.90%
Fatty acids as soap		7.32%
Soap		7.88%
Neutral fatty oil		9.31%
Mineral oil	67.25%	

Water, alcohol etc., 10.68%.
Free fatty acids after standing 24 hours, 4.28%
= 8.42% segregation.
Free fatty acids of well mixed oil, 5.08%

The above is an analysis of a soluble oil which, in its original condition, is a clear, red, fluid oil possessing an alcoholic odor and a slight bloom.

The main defect in this oil is its segregation, which consists in the precipitation of soap and fatty matter, this material settling slowly to the bottom of the container.

Emulsion is good, very slight separation of curd and mineral oil.

This oil could be recommended as a good oil except for its segregation. The price is 45 cents per gallon. Its general composition follows:

Mineral oil	67.25%
Neutral fatty oil	9.31%
Free fatty acids	5.08%
Soap	7.88%
Water, alcohol, etc.	10.68%
Total	100.20%

Oil No. 7

	Method A	Method B
Total saponifiable matter	12.70%	12.80%
Total fatty acids		12.54%
Free fatty acids		4.23%
Fatty acids as fat		0.57%
Fatty acids as soap		7.74%
Soap		8.34%
Neutral fatty oil		0.83%
Mineral oil	79.08%	

Water, alcohol, etc., 7.60%. Segregation, none.

The above is an analysis of a soluble oil which is a

clear, dark-red, fluid oil possessing an alcoholic odor and a deep blue bloom.

This oil is almost identical with Oil No. 4, excepting that it contains less saponifiable matter; it is made by a different manufacturer.

This oil can be recommended in every respect as a high-class oil. The price is 50 cents per gallon.

The general composition of this oil is about as follows:

Mineral oil	79.08%
Neutral fatty oil	0.83%
Free fatty acids	4.23%
Soap	8.36%
Water, alcohol, etc.	7.60%
Total	100.10%

Oil No. 8

Total saponifiable oil	24.87%
Mineral oil	74.72%
Total	99.59%
Free fatty acids	12.76%
Specific gravity at 60 deg. F.	0.892
Baumé at 60 deg. F.	26.9 deg.
Flash test	355.0 deg. F.
Fire test	390.0 deg. F.
Viscosity at 100 deg. F.	111.0 sec.

The above is an analysis of a straight cutting oil, a turbid, odorless, dark colored oil which contained precipitated fats, probably stearine or stearic acid, this precipitate settling to the bottom of the container upon standing.

This oil should be rejected for excessive free fatty acids and for low viscosity. The price is 45 cents per gallon.

Oil No. 9

Total saponifiable oil	32.20%
Mineral oil	67.60%
Total	99.80%
Free fatty acids	4.15%
Specific gravity at 60 deg. F.	0.889
Baumé at 60 deg. F.	27.5 deg.
Flash test	396.0 deg. F.
Fire test	440.0 deg. F.
Viscosity at 100 deg. F.	192.0 sec.

The above is an analysis of a straight cutting oil, a clear, dark-red oil, possessing a slight blue bloom and a lard oil odor. There is no segregation in this oil and the separated saponifiable oil is light-colored and free from objectionable odor.

This oil can be recommended for moderately low free fatty acid content, adequate viscosity, flash and fire test and for good general composition. It can be safely used on all such cutting work for which it would prove satisfactory.

The price is 60 cents per gallon.

Oil No. 10

Total saponifiable oil	11.60%
Mineral oil	88.00%
Total	99.60%
Free fatty acids	3.10%
Specific gravity at 60 deg. F.	0.900
Baumé at 60 deg. F.	25.4 deg.
Flash test	360.0 deg. F.
Fire test	410.0 deg. F.
Viscosity at 100 deg. F.	164.0 sec.

The above is an analysis of a straight cutting oil, a black-colored, opaque oil with a very disagreeable odor. Saponifiable oil has a rotten odor, suggesting Dippel animal oils.

This oil should be rejected for poor composition, being compounded from inferior animal oils.

Oil No. 11

Total saponifiable matter	18.88%
Mineral oil	81.00%
Total	99.88%
Free fatty acids	2.08%
Specific gravity at 60 deg. F.	0.883
Baumé at 60 deg. F.	28.5 deg.
Flash test	410.0 deg. F.
Fire test	455.0 deg. F.
Viscosity at 100 deg. F.	176.0 sec.

The above is an analysis of a straight cutting oil, a clear, reddish oil, possessing a slight blue bloom and a slight lard oil odor. Saponifiable oil is light colored, with an odor of lard oil. There is no segregation in this oil.

This oil can be recommended for purity of composition, low free fatty acid content, adequate viscosity, high flash and fire test and moderate price.

It can be safely used for all such cutting work, for which it will prove satisfactory. The price is 37 cents per gallon.

Remington Arms Company of Delaware.
Eddystone, Pa.

Industrial Wastes Disposal*

By Harrison P. Eddy

Of Metcalf & Eddy, Consulting Engineers, Boston and Chicago.

While there are various waste materials resulting from the industries, the term "industrial wastes" has come to mean the liquid wastes from the processes employed in industrial establishments. In England they are called "trade wastes"—a term not quite as applicable in this country, although occasionally used. Neither the human excrement of operatives nor their wash waters are comprehended in this term, although in many cases there is no effort to prevent their admixture.

ORIGIN OF INDUSTRIAL WASTES.

Many industries employ great quantities of water for various purposes such as condensing, washing of raw stock, dilution of chemicals, transportation and application of materials and the washing and rinsing of finished products.

Some of these uses do not defile the water and it can be discharged at will, as for example many condenser waters. Other uses result in a very great change in the character of the water and render it unsuitable for discharge into some waterways.

In paper mills, after the digestion of the raw stock with strong chemicals, there remain the liquors, highly charged with mineral and organic substances, but for which the manufacturer has no further use. He therefore seeks to get rid of them in the most expeditious and least expensive manner. The fibrous stock is then washed and large quantities of wastes are discharged from the washers, more or less highly charged with substances like those already mentioned. From the paper machines come great quantities of water carrying fine fiber, clay, coloring matter and other substances depending upon the character of paper made and the processes employed.

In tanneries, pure water is indispensable, but after use it is highly colored, charged with spent chemicals and loaded with organic matter. Its burden of im-

*A paper read at the Buffalo meeting of the American Institute of Chemical Engineers, June 20, 1917.

purity is partly in suspension and partly in solution. Wastes from different processes within the same tannery often react upon one another, throwing out of solution substances which in their new physical condition may be deposited in waterways to their detriment. Some tannery wastes of themselves are so resistant to bacterial action that they do not readily putrefy, yet when diluted with the waters of a natural stream they may become most offensive.

The wastes of woolen mills vary radically from those of paper mills and tanneries, yet they may be the cause of just as serious complaints. The grease and soaps from the scouring of the wool, the spent dye liquors, the soaps from the cloth-washing and the rinse waters in the aggregate, are of great quantity, highly colored, turbid, charged with suspended matter and quite capable of transforming an attractive stream into an unsightly, foul-smelling and quite unattractive waterway.

Instances like the foregoing might be multiplied almost without end. Some of the other industries which have encountered difficulties in the disposal of wastes are wire-drawing and galvanizing works, carpet mills, dyeing and bleaching works, strawboard factories, slaughtering and packing houses, breweries, distilleries, gas works, chemical and explosive works, and mines and coal washing plants.

EFFECTS OF WASTES UPON WATERWAYS

The ingredients of industrial wastes may be grouped in three main classes: first, floating and suspended matter; second, substances in solution, in colloidal condition and in an extremely fine state of suspension, and third, bacteria.

Floating and suspended substances may render the waters into which they are discharged, unsightly, and cause deposits. Such deposits, if of organic matter, often deprive the overlying water of a large proportion of its natural content of dissolved oxygen which is necessary for the maintenance of biological equilibrium and the prevention of putrefaction. Decomposition is accompanied by the generation of large quantities of gas, some of which is entrained in the mud until it has accumulated sufficiently to enable it to buoy up large masses which may be seen floating for a time upon the surface of the water only to be broken up and redeposited upon the liberation of the gases.

Dissolved substances almost always accompany the suspended matter in industrial wastes. Sometimes they are much more troublesome. They, too, cause the depletion of the oxygen supply, usually through the action of the bacteria of decomposition. Particularly objectionable and difficult to treat are those wastes containing large quantities of very finely divided suspended matter and colloidal substances. Usually impurities of this class pass along with the waters of the stream into which they are discharged and do not form deposits. However, under some circumstances such ingredients are coagulated and thrown down, sometimes by the reaction of wastes of one process with those of another, and at others by natural physical, chemical and biological processes going on in the waters.

Most industrial wastes contain bacteria. These may not be pathogenic germs. In fact, they may be decidedly helpful in the problem of disposal, rather than harmful. There are abundant opportunities in some of the industries, however, for the pathogenic organisms to escape in the liquid wastes and thus contaminate the waters into which such wastes are discharged. One of the most dreaded organisms which may be spread about in this manner is the anthrax bacillus, sometimes present in hides, skins and wool. This organism is very hardy and appears to maintain its virility through its spores for many years.

Excrementitious matter from operatives is often combined with the industrial wastes and thus the entire flow may be rendered bacterially dangerous.

Wastes may cause objectionable conditions in many ways depending upon their character and the size and condition of the waterway into which they are discharged. They may contaminate a water supply, render a stream unsightly and objectionable in appearance, cause putrefying deposits, render the natural waters putrid and offensive, poison or otherwise kill fish, and injure vegetation. Strange and contradictory as it may sound, complaint is frequently made that wastes are killing vegetation and about equally often that they are so encouraging the growth of vegetation as to do serious damage. If one complaint doesn't apply the other usually does.

It might appear that as the industries are the offenders in this field of activity, there would be few complaints from them of the conditions produced by the discharge of industrial wastes. Just the contrary is true. One of the most common complaints comes from the manufacturer to the effect that an upper riparian industry is rendering the water unfit for use in his plant.

SELECTION OF FACTORY SITES.

Enough has been stated to show how wide-spread is the trouble in disposing of industrial wastes. When about to establish a new industry or plant, the proprietors usually make thorough investigation of the quality of the water available for their use. The extent of the supply is also generally investigated and often such collateral questions as the amount of power derivable from the passing stream. But how infrequently do they make even a superficial study of the problem of wastes disposal. Yet this may be a greater and more difficult problem than that of water supply.

Expenditures of $100,000 or $200,000 for wastes treatment plants and of $25,000 to $40,000 annually for the operation of such plants are becoming more and more frequent. Capitalizing the annual expenditure of $25,000 at 5 per cent and adding $100,000 for construction cost, making no allowance for depreciation, it appears that the industry might have expended as much as $600,000 in procuring a site which would not have entailed the necessity of wastes treatment.

The selection of a suitable site for an industry producing large quantities of wastes is a matter of much importance. Even though conditions at the outset appear to be favorable they may be materially altered by establishment of new industries down-stream or by an increase of riparian population below the plant.

TREATMENT OF WASTES

When it is impracticable to afford the wastes sufficient dilution to prevent the production of unsatisfactory conditions, it becomes necessary so to modify the character of the wastes that they will not cause complaint.

One often hears that wastes cannot be so treated; that if a way were known the manufacturer would gladly adopt it. This impression that the wastes cannot be successfully treated is in many cases not true, and it may be accepted that they can be so treated as to remove their objectionable and deleterious properties before their discharge into natural waterways.

On the other hand, such treatment may be and often is a very expensive undertaking and one from which the manufacturer naturally shrinks on this account and also because he personally is not familiar with the process necessary to the accomplishment of the object.

Perhaps the most important step in the solution of this problem is the determination of the extent of treatment necessary to meet the requirements of the case. To answer this question intelligently it is necessary to know the character and quantity of the wastes produced, the character of and conditions surrounding the waterway into which they are being discharged, and their effect upon the waters in question.

The next step is to determine how best to treat the wastes to accomplish the necessary results at a minimum cost and, in any event, one which is not prohibitive. There have been instances when the plant proposed for such treatment would have cost a sum about equal to the value of the entire industrial plant of which it was to become a minor part. Such a suggestion is absurd and tends to reduce or extinguish the respect of the manufacturer for the party making the suggestion, for the officials trying to enforce the laws, and even for the laws themselves.

For the removal of the suspended matter screening may suffice under some conditions, while others may require the more complete removal by sedimentation. When the substances in suspension are of very light specific gravity and finely divided, it may be necessary to resort to chemical precipitation.

Some dissolved matters may be removed by chemical precipitation, while others can be modified in character by chemical treatment without actual removal. If they are organic and subject to putrefaction, bacterial action may be required for their oxidation, as in sewage treatment.

Certain wastes are bacterially dangerous and it may be necessary to destroy the pathogens even where the suspended and dissolved matters would cause no harm. In such cases the treatment of the wastes may be all that is essential, while in others it may be necessary even to treat the raw material as has been suggested in the case of anthrax-infected hides.

It should not be inferred from this discussion that a single process can be selected for each case, for it often requires several to accomplish the desired result.

At one plant where the author's firm has supervisory charge of the wastes disposal department, no less than seven steps have been employed at one time. These are degreasing of a portion of the wastes, sedimentation of the wastes, chemical treatment of the settled effluent, filtration of a portion and dilution of the remainder of the chemical effluent and finally the introduction of chemicals to prevent the exhaustion of the supply of oxygen in the river.

VARIATION OF TREATMENT FROM TIME TO TIME

The process adopted should in many cases be varied from time to time to take advantage of favorable or to offset unfavorable conditions. The volume of business being done may materially affect the quantity of wastes produced and correspondingly make the condition dictating treatment more or less exacting. Industrial processes frequently are changed requiring modification in the treatment methods.

In winter temperatures may be sufficiently low to retard or even prevent putrefaction under conditions which in summer would transform a natural waterway into a stinking slough.

In spring there are usually large volumes of diluting water which may make bacterial oxidation in filters unnecessary, at a time when the filters would be working under most unfavorable conditions.

All of these and innumerable other conditions must be taken into consideration if success is to be attained at a minimum cost.

ADVISABILITY OF ANTICIPATING COMPLAINT

In many cases industrial establishments which are now of great size have grown from very modest beginnings, often from merely a room or two adjacent to a water privilege which was the primary reason for the selection of the site. As the business has grown through the decades conditions have entirely changed. What was an abundant supply of water not only for industrial purposes but also for the dilution of the wastes, has now become barely adequate for industrial purposes alone and the entire flow now passes through the plant and perhaps through several plants more recently built. Thus the entire stream has become a river of industrial wastes rather than, as originally, a natural river into which a minor quantity of industrial wastes was discharged.

In all such cases there has been a collateral increase in the resident population. Now there are villages along the river where formerly were wooded lands and pastures. Such development has brought with it demands for parks and other recreation facilities, including the improvement of the natural stream for boating and perhaps for bathing purposes.

Under some conditions a proscriptive right may be acquired to make certain uses of the waters of the river, even though they be more or less hostile to the enjoyment of some privileges by lower riparian owners. The proscriptive right is often advanced in defense of the practice of discharging untreated industrial wastes into waterways and their consequent pollution. Many of the industries, particularly in the eastern part of the country, are of very long standing. The continuous operation of an industrial plant devoted to the same general kind of work for more than a century can be cited in numerous instances. In comparatively few cases, however, can it be shown that such industries are operating under conditions substantially identical with those of prior decades. Either the character of the business has changed so that processes are different and industrial wastes are greater or less in quantity and decidedly altered in character, or the business as a whole has become much greater with a corresponding increase in the quantity of industrial wastes. These changes make it exceedingly difficult in most cases to establish a proscriptive right to the acts of which complaint is made.

It should be borne in mind that in no case can one acquire a right, by proscription or otherwise, to create a nuisance. This fact has been the stumbling block upon

which many an effort to secure or maintain privileges, through court decisions, has been defeated.

The paramount lesson to be gained from experience in these matters is that it is wise to anticipate complaint of objectionable conditions whether from lower riparian manufacturers influenced by difficulties caused by the character of the water, from a community complaining because of odors and objectionable appearance of the stream, or from the farmer whose cattle will not drink the water, whose crops are killed because of inundation by polluted waters, or whose ditches and natural brooks have become so overgrown with vegetation due to the fertilizing ingredients of the waters having their origin in industrial wastes, that they will no longer serve their purpose.

The prudent manufacturer will make it a part of his routine business carefully to observe the effect of the discharges from his plant, upon the character of the water in the river, not alone in his immediate vicinity, but for a considerable distance down-stream. When conditions become noticeably objectionable he will take measures to remedy them, at the same time maintaining the valuable privilege of utilizing the stream for the disposal of his wastes to as great an extent as is compatible with the public good and the reasonable use of the waters by lower riparian manufacturers. Such a policy, if intelligently pursued, will result in many cases in avoiding expensive litigation. More important than this, however, is the fact that by maintaining the waterway in a reasonably satisfactory condition the hostility of lower riparian dwellers may be avoided. Where such a feeling is aroused by objectionable conditions, it may exert itself through legislation or through litigation in such a manner as to require the establishment of exceedingly rigid restrictions as to the use of the river or even drive the industries away. Numerous instances of the latter can be cited.

NEPONSET RIVER AN ILLUSTRATION

One of the most interesting illustrations of the industrial wastes disposal problem is that of the Neponset River Valley near Boston in Massachusetts. This river rises about 22 miles from Boston Harbor into which it discharges. Its natural drainage area is 114.14 square miles and it also receives one-third of the flow of the Charles River at Dedham, equivalent to the drainage from 66.2 square miles. The total tributary area is therefore 180.3 square miles.

The normal yield of the drainage area is probably about as follows:

Month	Mil Gal. Daily	Cu. Ft. Per Sec.	Month	Mil Gal. Daily	Cu. Ft. Per Sec.
January	216	334	July	31	49
February	304	470	August	45	69
March	492	762	September	40	62
April	356	551	October	76	117
May	190	294	November	135	209
June	84	130	December	176	272
Mean				178	276

The actual flow is much more uniform than the natural flow would be because of the regulating effect of the storage reservoirs.

The State Department of Health reported at one time that there were about 30 mills discharging more or less wastes into this river. Before prohibitory statutes were passed, one wool scouring concern abandoned its location. Some manufacturers have diverted a portion of their business to other plants and one has abandoned the manufacture of one line of goods, thus avoiding the production of a large quantity of liquid wastes which were very difficult to treat.

Eleven manufacturers have provided sedimentation tanks and ten have constructed strainers and filters of cinders, coke or sand. Some have adopted chemical precipitation as a means of improving the efficiency of natural sedimentation. Treatment plants have been provided in nearly all cases where the wastes require treatment, some of which were described by the writer in a paper entitled "The Cleaning Up and Improvement of a Stream Polluted by Sewage and Trade Wastes," published in *Engineering and Contracting*, Aug. 9, 1916.

In 1902 the Massachusetts Legislature passed an act directing the State Board of Health,

"* * * * to prohibit the discharge of sewage * * * or every other substance which may be injurious to public health or may tend to create a public nuisance or to obstruct the flow of water, including all waste or refuse from any factory or other establishment where persons are employed, *unless the owner thereof shall use the best practicable and reasonably available means to render such waste or refuse harmless.*

"Section 2. The Board shall consult and advise with any such owner at his request or of its own motion as to the best practicable and reasonably available means of rendering such waste or refuse harmless, having regard to the circumstances and requirements of the situation and to the industrial interests involved." (Chap. 541, Acts of 1902.)

It is interesting to note that it was the intention at the time this original act was passed, to have reasonable regard for the manufacturing industries, not requiring them to go to extremes in the treatment of their wastes unless the exigencies of the situation required. In other words, incorporated into this statute was the "rule of reason."

At the time of the passage of this statute industrial wastes treatment in this country was in its infancy and progress in improvement of conditions in the Neponset Valley was naturally somewhat slow. In 1906 it appears that public sentiment had been so aroused that it was possible to pass an act in which the "rule of reason" was much less evident than in the earlier act. The only reference to it in the 1906 act was that the Board was to advise the owner of the factory as to the "*best practicable and reasonably available means of rendering the wastes or refuse harmless.*" The clause "having regard to the circumstances and requirements of the situation and to the industrial interests involved" was omitted from this act.

During the next 10 years many efforts were made to secure additional and usually more drastic legislation, in spite of the fact that the manufacturers expended large sums of money in an effort so to modify their wastes before their discharge that they should not endanger the public health nor tend to create a nuisance. Perhaps the culmination of these efforts may be said to have been embodied in a proposed act—Senate 113—presented to the Legislature for its consideration in the year 1916, which read as follows:

"Section 1. Any person, firm, corporation or group of individuals who shall cause, either directly or indirectly, the pollution of the waters of any river in this commonwealth, shall be punished by a fine of not more than one hundred dollars for every day which said pollution continues after notice from the health commissioner that such nuisance be abated.

"Section 2. A river shall be held to be polluted within the meaning of this act whenever by the introduction or discharge into its waters of any foreign or deleterious substance: (a) it shall give out any noxious or offensive smell, odor or vapor, which condition is a menace to the public

health; (b) it shall become discolored in such a way as to be unsightly or offensive, or (c) it shall become poisonous or dangerous to fish or animal life subsisting therein, or to live stock using the same as a drinking place; (d) it shall become injurious to vegetation in its vicinity.

"Section 3. The health commissioner of Massachusetts shall be charged with the enforcement of the provisions of this act and shall determine when the waters of any rivers are being polluted as aforesaid.

"Section 4. All acts or parts of acts inconsistent herewith are hereby repealed."

There are several provisions in this act which would be exceedingly oppressive if applied with literal interpretation of the act and without reading into it the rule of reason. One of these is the provision for a fine not to exceed $100, for every day which the pollution continues after notice from the Health Commissioner that such nuisances be abated. In some instances, even if prosecuted with diligence plants for the elimination of those ingredients of wastes which caused the pollution, could not have been built in less than six months' time.

Aside from the broad scope of the specifications of a polluted river within the meaning of this act, the Health Commissioner was charged with its enforcement and apparently made the sole judge to determine when the waters of the river were being polluted, as specified by the act. Should such an act be found constitutional, which is subject to some doubt, it would apparently deprive the alleged offenders of their rights to a hearing before the courts of justice.

Happily this act was not passed and is introduced here merely as an example of the extent to which industries or communities may go after they have become thoroughly aroused by long-continued objectionable conditions. It is confidently believed that such drastic legislation can always be avoided, and probably also its suggestion forestalled, by prudent foresight on the part of manufacturers in preventing objectionable conditions caused by the discharge of their untreated wastes.

PROGRAM FOR SOLUTION OF PROBLEM

In many cases where manufacturers have been confronted with a serious problem in connection with the disposal of their industrial wastes, they have been inclined to attempt its solution without first acquiring a clear understanding of the scientific principles involved, either in the production of the conditions which caused the trouble or in the processes available for the treatment of the wastes to render them less objectionable. The treatment of industrial wastes usually is a subject entirely different from that with which the manufacturers have to deal in their usual business and in which they are primarily interested, all other matters such as the treatment of their waste liquors, being of only secondary interest and importance from their point of view. They have, therefore, often adopted a plant poorly adapted to the use they desired to make of it. Sedimentation tanks, for example, are often found which are entirely inadequate for the purpose, although this process is most simple. All sorts of filters have been designed and constructed, but usually without the remotest conception of the scientific principles involved in the treatment which they were to accomplish.

Another fruitful source of misdirected energy has been the desire to recover from the wastes ingredients of value such, for example, as the grease and fertilizing ingredients in municipal sewage. Industrial wastes, like sewage, often contain ingredients which have a market value, and every encouragement should be afforded to the recovery of such products. As economic conditions change in the future there will be a greater need of economizing in this direction, and it is to be expected that processes will be devised for the profitable recovery of such ingredients. The fact that such processes may not be available at the time the problem first presents itself, but will probably be available at some future time, is not a justifiable reason for making no effort for its solution.

Whenever an industry is confronted with a problem of this kind a program for its solution should be carefully worked out before making expenditures upon construction. In fact, the studies necessary to the preparation of such a program may disclose other means of solution, involving relatively small cost.

First a study should be made of the waterway, to note its condition and physical characteristics, such as size, velocity of flow, depth and temperature, and a similar study of wastes to determine their quantity and character. With the information gained in this manner it will be possible to form an opinion as to the extent of treatment required to meet existing conditions.

Next, the kind of treatment and the plant required to provide such treatment, should be determined. The methods selected should be those required to give the results which may be desired within a reasonable period of time in the future when perhaps conditions may have become decidedly different from those obtaining at the time the investigation is made. Such methods should always be selected and reported with the clear reservation that better processes may subsequently be devised.

Following the selection of methods should be the construction of plant. Here it may be wise to proceed progressively, building first the system of drains required for the collection of the wastes and for their discharge at a single point. After this has been done further investigations based upon the measurement and analyses of the combined wastes, may be desirable. When the collecting system shall have been completed, it will be possible to provide the first part of the treatment process, such for example as screening or sedimentation. After this has been accomplished still further investigations may be desirable to determine, first, the efficiency of the plant already installed and, second, the next process of treatment which should be provided and the probable results to be obtained.

However much or little may be required, it is important to build in accordance with an intelligently devised plan and in harmony with such additional processes as may follow. Thus many expensive mistakes will be avoided and advantage taken of all opportunities to provide an economical arrangement of plant. The following of such a course will often result in avoiding expensive pumping of the wastes, or the treatment of excessive quantities due to the inclusion of relatively clean waters which may not require treatment under the local conditions.

The final step, and undoubtedly the most important, is the intelligent operation of the plant. Whether the processes involved are simple or complex the supervision and control of operation should be based upon a knowledge of the conditions in the river, the character of the wastes and the scientific principles involved in their treatment.

Synopsis of Recent Metallurgical and Chemical Literature

General Metallurgy

Recent Operations at the Consolidated Mining and Smelting Company.—In a paper given at the recent mining convention held in British Columbia, S. G. BLAYLOCK, general manager of the Consolidated Mining & Smelting Company, Trail, B. C., told of developments at his company's plant since the war started. Just before the war was declared and the markets were overflowed, and everyone expected a panic, the Consolidated Company had its vaults full of silver which it could not sell. Shortly after the war started, however, conditions began to improve and the markets and the stock exchanges started again and metals moved. Zinc jumped to a fabulous price. The company had been primarily a producer of lead, gold and silver. Some experiments had been conducted with zinc, but the men in charge of the work had enlisted. The experiments were started again, however, and a contract was taken on with the Imperial Munitions Board to make zinc. A plant was built, which cost a great deal more than was expected as so many things had to be changed as the process was perfected. At present about 40 tons per day of electrolytic zinc is being produced. A copper refinery was also built when the copper shortage became acute, and the company is producing 30 tons of refined copper per day. A copper converter plant was also constructed. Just about the time the copper plant was being built the company was notified by the concern from which it had been buying hydrofluosilicic acid for the lead refinery that it would either have to make a contract for three or four years ahead at about double the price or they would furnish no more. Hence a hydrofluosilicic acid plant was built and that necessitated a sulphuric acid plant, which was also built. These have been operating for several months. Since the building of the first sulphuric acid plant the requirements have increased so that the plant has been doubled. At present about 1600 men are employed and the following products are being made: electrolytic copper, copper sulphate, electrolytic lead, lead pipe, shrapnel, wire, electrolytic zinc, gold, silver, sulphuric acid and hydrofluosilicic acid. All of these with the exception of lead, gold and silver have been accomplished since the war started and were caused primarily by the need for the material by the Munitions Board. The author stated that 300 men—practically every unmarried Canadian or Britisher—had gone to the front.

Electrolytic Zinc

Difficulties in the Electrolytic Zinc Process.—At the recent mining convention held in British Columbia, Mr. THOMAS FRENCH of the Nelson Electrolytic Zinc Company, Nelson, B. C., read a paper on "Some of the Difficulties in the Electrolytic Zinc Process." He said one of the greatest difficulties both in early work and at the present time is in the roasting of ore so as to get a high extraction of the zinc. Mr. French's father, A. Gordon French, had used niter cake successfully in roasting and had obtained high total extractions, but it was later proven by the author to be unnecessary to use niter cake if certain precautions were taken in roasting. He said he had roasted a great number of ores and had generally obtained 90 per cent extraction. The Consolidated Company at Trail became interested in the process and made experiments in a large Wedge furnace, with seven hearths and 22 ft. 6 in. in diameter with high extractions. The author said he understood that the Consolidated Company was only obtaining 65 per cent extraction at present and that at Anaconda somewhat similar results are also being obtained. He thinks that these low extractions are due to improper roasting. The author stated that his father had found that manganese, contrary to the general opinion, was necessary in the zinc solution for the successful deposition of zinc. One of its main functions is to prevent the disintegration of the lead anodes. In addition to that the manganese has several other effects, such as giving a lower current consumption, and providing a valuable by-product of manganese dioxide. By the use of manganese the anodes are not absolutely protected, but with the addition of a little sulphate of soda the protection is absolute. Most of the manganese is deposited as manganese dioxide at the anodes and the remainder left in solution flows from electrolytic vats, along with the acid that has been set free, and is used again in the operation of dissolving the roasted ore, for the purification of the solution. In his father's Canadian patent specification dealing with the electrolytic part of the process he claims "the electrolyzing of a solution containing sulphate of zinc and sulphate of manganese for the recovery of zinc and of manganese." And also of a solution containing sulphate of zinc, sulphate of manganese, and sulphate of sodium for the recovery of zinc and of manganese dioxide. In the American patents, the claims—in order to save duplication of patents—are drawn up rather differently. They claim the electrolyzing of a solution containing sulphate of zinc, sulphate of manganese and sulphate of sodium. It was considered that it was quite safe to do that, as sulphate of sodium exists in practically every ore and collects in the solution.

Utilization of Waste Leather

London Chemical Industry Club Meeting.—An account of the first meeting of the new Chemical Industry Club in London is given in the *Chemical Trade Journal and Chemical Engineer*. The membership, for the present, is restricted to members of the London Section of the Society of Chemical Industry, and although among those who have signified their intention of joining are many living outside the London area, yet the general invitation of the committee of the club to all members of the section to attend the first meeting was responded to to such an extent as to fulfill the most sanguine expectations of those who are working so hard to make the new venture a success from the start. The actual membership at present is about 350, but a total of 500 is regarded as easily attainable, and there are one or two enthusiasts who feel that, with a subscription of only 2s. 6d., the whole of the 1000 members of the London Section should join. To assist the finances a number of donations have already been received. A paper was read by Mr. M. C. LAMB, and dealt with a subject upon which, at the request of the War Office, he has undertaken an investigation, viz., the commercial utilization of discarded army boots and other waste leather. The object of the paper was to incite the formulation of further suggestions for the utilization of this waste product on a commercially profitable scale.

The present policy of the Director of Army Contracts is to have old army boots sorted into four categories, the first three of which are sold for civilian use, and the remainder are available for waste. The actual quantity, which many of the members were anxious to know, was not stated by the author of the paper, the impression being not that he did not know, but that reasons of policy forbade the information being given. He indicated, however, several interesting directions in which experiments are being carried out to make use of discarded army boots. The most promising at the present moment is for the purpose of road-making. By dry distillation the quantity of charcoal obtained has been found to be about 25 per cent of the waste leather used. Then the uppers have been found to give some 15 per cent of extractable grease, and a quantity of crude ammonium sulphate has also been recovered. Another direction in which experiments have been made is in the treatment of the waste leather as an artificial manure; finely powdered and mixed with niter cake. However, not very successful results have been obtained, owing to the presence of soda salts. Decolorization carbon is another possible recovery, which should have commercial possibilities, having regard to the present shortage. Leather boards were also mentioned as likely to be attractive commercially, while a glue of inferior quality has also been evolved. Mr. Lamb's paper certainly created the interest which was desired. The use of waste leather in some of the directions indicated is not new, but the quantity which will be available from discarded army boots will be so large that considerably greater ingenuity may well be given to the problem in the knowledge that the supply will not fail for a very long time. Specimens of the by-products mentioned were shown to the members of the club.

Dust Collection and Ventilation

Dust Collecting and Ventilating in Factories.—In an address delivered on May 8, 1917, before the Illinois Manufacturers' Association and the National Safety Council, Mr. W. G. CLARK, president of the Clark Dust Collecting Company, Chicago, Ill., gave some interesting data on dust collection. Some of the most prominent industries in which dust collecting and ventilating systems can and should be used are as follows: Metal smelting and refining works, ore separating and mixing, carbide of calcium plants, crushing and grinding plants, cement mills—all departments, cereal mills, grain elevators, chemical works, gypsum works, hydrating plants, blast furnaces, graphite mills, asphalt manufacturing, flour mills, fertilizers, gum factories, cork factories, coal mines, phosphate plants, lead works, on sand-blast machines, malt houses, potteries, paint mills, shoe factories, polishing plants, wood-working factories, peat coal briquetting works, breweries, emery mills, foundries, collieries, gas works, drying plants, oxide plants, textile mills, sugar factories, jute mills, porcelain works, rubber factories, spinning mills, tanneries, tobacco factories, felt boot, tire factories, dextrine factories, munition plants, etc. Referring to metal smelting and refining works the author said there was a time when they let escape through the stacks from their furnaces valuable oxides and other valuable metals that they are now collecting and saving, and selling at a very fancy price, some places realizing a profit from $100 to $400 per day. In the cement industry there is a great deal of interest being taken in solving dust problems. There was a time when cement mills thought that dust was unavoidable, and that it was part of their business to have a lot of dust floating around, that it was part of the game, but in late years we notice a marked change in their opinion. Cement dust is valuable. They spend hundreds and thousands of dollars in pulverizing and grinding machinery to pulverize their raw and finished material into a fine powder such as cement is, and they figure it is foolish to let it escape and get away from them in this condition. Therefore, they are putting in dust systems to reclaim this fine dust. It reduces the cost of manufacture, and economical manufacturing of all products is looked after more carefully than in former years. They also figure that by eliminating the dust the sanitary condition is so much improved that it pays to have this improvement, as they secure a better day's work from their employees, and save wear and tear on their machinery. Irritating dust in sand blasting plants is also receiving the attention of all classes connected with this industry, from the State factory inspector, employee and employer. This is a very hazardous and very unsanitary business at its best, and the better condition existing in these industries the more work is accomplished, the less wear on men and machinery, and it is remarkable to see the interest that the conscientious employers are now displaying in this direction. On poisonous gases the same interest is being shown, and the U. S. Government is pushing the rigid investigation on poisonous dust, all of which combined with the willingness on the part of successful smelters are reaching grand results.

Aluminium

Action of Acetic Acid on Aluminium.—A paper on this subject was presented by RICHARD SELIGMAN and P. WILLIAMS at a recent meeting of the London Section of the Society of Chemical Industry and published in the April 30, 1917, issue of the *Journal* of the society. In an earlier paper (*Jr. Soc. Chem. Ind.*, 1916, 35, pg. 88) the action of boiling concentrated acetic acid was described. In the present paper the action of boiling acetic acid of lower concentrations and of acetic acid of all concentrations at ordinary temperatures is described. The action of boiling acids of lower concentrations has been found to be analogous to that of the solutions containing between 100 per cent and 50 per cent acetic acid previously examined, and it has been found that the rate of dissolution of the aluminium rises continuously until the concentration of the acid falls to 1 per cent. With acids of lower concentration than 1 per cent it is not possible to obtain reliable figures owing to the fact that the metal becomes coated with a protective skin which interferes with the action of the acid. Even with solutions containing 5 per cent acetic acid the numerical results become erratic owing to the same cause, but it is, nevertheless, possible to conclude definitely that where unprotected by a coating the aluminium dissolves at an ever-increasing rate.

"The rate of attack by cold acetic acid is in general small. As in the case of boiling acids, the rate of dissolution increases with increasing dilution of the acid, and the highest rate so far noted took place with a solution containing 0.02 per cent acetic acid. The rate of dissolution is frequently high at first, but rapidly falls off and then remains approximately constant over pro-

longed periods. This phenomenon has not been explained so far but does not appear to be of practical importance.

"In dealing with cold acetic acid it has been possible to show conclusively the effect of oxygen in promoting local action. Acids which normally cause local action of a serious kind can be made to act perfectly uniformly if the oxygen be entirely removed or if it be replaced by some inert gas. No doubt this accounts also for the fact that acids which in the cold or even at temperatures slightly below boiling point cause local action, nevertheless act perfectly uniformly at boiling temperatures when the oxygen is rapidly removed in the course of ebullition. In the case of cold acids it has been found, moreover, that the actual rate of dissolution is increased by the presence of oxygen, and may be reduced to less than half its original magnitude if the oxygen be replaced by hydrogen.

"Here again it may be well to point the practical moral of the observations made. Vessels used to contain solutions of these acids should not be allowed to remain wet for prolonged periods after being emptied and before cleaning. In such cases the metal is exposed to the action of thin films of acid subjected to intense aeration and, as practical experience has amply demonstrated, local attack frequently ensues. The metal should be purged as soon as possible of any remaining acid and, where practicable, left dry.

"One of the original objects of this research was to find an explanation of the fact that in stills used for the distillation of acetic acid the still proper was often found to have a prolonged life, whereas the condensers, notably in their lower part, were frequently subjected to rapid deterioration and to local perforation. It would appear that the effect of oxygen in promoting and localizing such attack affords a sufficient explanation of this phenomenon, because it is precisely at the point where this attack has been observed in condensers that oxygen would have access to surfaces bathed in hot acids.

"The question arises whether difficulties due to this cause could not be completely obviated by the introduction of some neutral gas at this point, or by preventing altogether access of oxygen to the condenser."

The effect of various foreign substances was also discussed by the authors. "It has been found that with dilute acids of about 10 per cent concentration the addition of up to 1 per cent of sodium chloride, potassium bromide, potassium iodide or potassium nitrate has practically no effect in the case of boiling acid, whereas an equivalent amount of sodium sulphate raises the rate of dissolution appreciably. In cold 10 per cent acetic acid, however, 1 per cent of sodium chloride is sufficient to raise the rate of dissolution tenfold, whereas potassium bromide effects a much smaller increase in the rate of attack, and potassium iodide and potassium nitrate none at all; 0.5 per cent of sulphuric acid in the form of sodium sulphate raises the rate of dissolution fourfold in the case of dilute acid at normal temperature.

"The most serious effect of the addition of the substances experimented with was noted in the case of 80 per cent acid at boiling point. Here the rate of dissolution is raised by 1 per cent of sodium chloride from 290 to 16,000. By 1 per cent of potassium bromide the rate is only increased from 290 to 485, while potassium iodide and potassium nitrate may be said to have no effect; 0.5 per cent of sulphuric acid in the form of sodium sulphate increases the rate of dissolution."

Molybdenum

Metallurgy of Molybdenum in Canada.—In *National Progress* for June, 1917, G. C. MACKENZIE gives some data on the development of the mining, concentration and reduction of molybdenum ores in Canada. Canadian molybdenum purchased by the Imperial Munitions Board of Ottawa in the form of molybdenite concentrates is being converted into ferromolybdenum in Canada before being exported to Europe, and as it is possible to manufacture the ferroalloy from concentrates containing less than 85 per cent MoS_2, the following scale of payment has been adopted: For concentrates containing not less than 85 per cent molybdenite, $1.09 per pound of contained MoS_2; not less than 80 per cent, $1.05 per pound MoS_2; not less than 75 per cent, $1.02 per pound MoS_2; not less than 70 per cent, $1 per pound MoS_2. The mining and metallurgical treatment of Canadian molybdenum ores has up to 1916 played a very small part in the world's production. This has been due to various factors, chief of which have been the limited demand for the mineral and the unattractive prices, together with the fact that no Canadian mine had until 1916 been developed to the point of a steady producer. The Department of Mines has conducted a large amount of experimental work on concentration and has finally adopted a modification of the Wood water film flotation machine (invented by Henry E. Wood of Denver, Col.), which is used on a semi-commercial scale in treating ores at the Department of Mines Laboratories. The plant has operated since June, 1916, and up to Feb. 1, 1917, has treated 2397 tons of crude ore and picked flake with the production of 34.85 tons of pure molybdenite in the form of a concentrate averaging 80 per cent MoS_2. The ore treated contained 1.84 per cent molybdenite and the actual molybdenite shipped has been 79.09 per cent of the total amount received. The total recovery would be slightly over 80 per cent, as no account has been taken in this calculation of the several tons of middling product in process of milling.

Among the companies who are operating in Canada to produce molybdenum are The International Molybdenum Company of Orillia, Ont., who are under contract with the Imperial Munitions Board; The Canadian Wood Molybdenite Company, The Spain Mines, County of Renfrew, The Chisholm Mine, The Renfrew Molybdenum Mines, in Ontario; The Molly Mine in the Kootenay, and The Molybdenum Mining & Reduction Company of Vancouver, British Columbia.

Among the processes used in the manufacture are the Elmore vacuum flotation process, the Minerals Separation process, the Hoover valveless apparatus, and the Callow pneumatic flotation process.

Technical Positions Announced by Civil Service Commission.—The present demand for technical men by the Government gives rise to the constant creation of new positions. At present physicists, metallurgists, chemists, geologists and metallographists are needed. Full information regarding these positions together with application blanks may be obtained from the Civil Service Commission in Washington, D. C., and from the secretaries of the Civil Service Boards in Boston, Philadelphia, Atlanta, Cincinnati, Chicago, St. Louis, Seattle, San Francisco, New York and New Orleans.

Recent Metallurgical and Chemical Patents

Soldering

Soldering Aluminium.—A composition for soldering aluminium is patented by Francis E. J. Litot, of Wilkinsburg, Pa. It consists of an alloy of zinc, lead, and tin in the proportions of 25, 55 and 45 parts respectively. This composition is claimed to form a solder which is very fluid and has a low melting point and is therefore suitable for soldering aluminium. It is also claimed to form a joint which has great endurance under either mechanical strains or weather, and its melting point is so low that danger of injuring the aluminium during soldering is entirely avoided, even in the hands of an unskilled workman. (1,224,941, May 8, 1917).

Iron and Steel

Process of Treating Iron Ores.—A process for treating iron ores, patented by Edward F. Goltra of St. Louis, Mo., consists essentially in preheating or calcining the ore and its gangue at a temperature and for a sufficient length of time to drive off the moisture in the ore and to render the gangue easily separable from the ore. The ore is subjected to vigorous tumbling which separates the gangue and the product in this shape is then subjected to a strong blast, which removes the gangue from the ore. The concentrated ore then is subjected to blast-furnace treatment. Fig. 1 illustrates

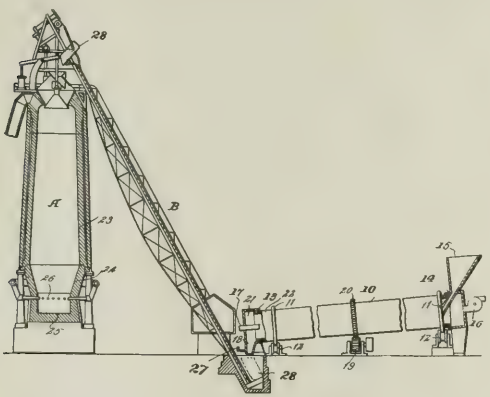

FIG. 1—GOLTRA'S PROCESS FOR TREATING IRON ORES.

the process. Ten is a rotating cylindrical kiln in which the ore is liberated from its moisture. At the lower end of this kiln is a burner and a blast pipe. The blast is intended to wash the charge and to penetrate in between the gangue and the values, loosening the latter from the gangue and in this manner making the whole product more suitable for blast furnace treatment. The rest is self-evident. (1,216,109, Feb. 13, 1917.)

Process for Making Ferro-Phosphorus.—John Jefferson Gray, Jr., of Rockdale, Tenn., has patented the making of ferro-phosphorus in a blast furnace. The process consists in charging the furnace with a suitable mixture of iron-bearing material, phosphatic material, fluxing material and excess carbon, the latter thus maintaining free uncombined carbon in the fusion zone. The temperature in the fusion zone should be high enough to reduce the phosphorus present in the phosphatic material to the elemental state in the presence of said free carbon. The temperature of the fusion zone is 2200 deg. Fahr. to 3100 deg. Fahr. This high temperature is produced by preheating the air blast to 900 deg. Fahr. The stock line temperature should not be higher than 700 deg. Fahr. The iron ore stack in the furnace should be high and have a slow downward motion so as to facilitate contact between the iron and the ascending phosphor vapor. (1,220,416, March 27, 1917.) A charge as used is given in the following table:

	Lb.	Lb.
Air		9,720
Phosphate rock:		
Tricalcium phosphate, $Ca_3P_2O_8$	1,050	
Calcium fluorid, CaF_2 / Calcium carbonate, $CaCO_3$ / Calcium sulfate, $CaSO_4$	224	
Silica, SiO_2	63	
Iron, Fe_2O_3	63	
Total phosphate rock		1,400
Iron ore:		
Fe	700	
SiO_2	252	
$Al_2O_3 + H_2O$	448	
Total iron ore		1,400
Silica, sand or flint:		
SiO_2	576	
K_2O	64	
Total		640
Coke, as carbon, C		1,840
		15,000

Copper, Lead and Zinc

Hydrometallurgy of Copper.—A patent to John H. Greenway, of Warren, Ariz., relates to the extraction of copper from ores and especially from oxidized ores. Sulphuric acid solutions are employed for the leaching. In general the process consists in passing a solution of sulphuric acid over ores containing copper and iron until the solution is substantially neutral. This neu-

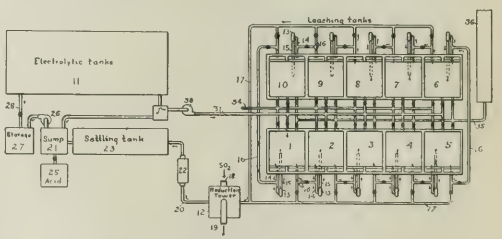

FIG. 2—GREENWAY'S PROCESS.

tral solution is then subjected to the action of sulphur dioxide which reduces the ferric sulphate to the ferrous state. The solution is then electrolyzed for the recovery of copper. The ferrous sulphate in the solution has no detrimental action on the deposition of the copper. Fig. 2 illustrates this process and needs no further explanation. (1,224,458, May 1, 1917.)

Electrolytic Zinc.—A patent has been granted to Urlyn Clifton Tainton of Johannesburg, Transvaal, South Africa, for the electrolytic recovery of zinc from ores or other zinc-bearing materials. One method of carrying out the process is as follows: The ore is first reduced to such a size as to render the zinc values readily accessible to the solvent. If the ore is sulphide it is primarily roasted to make it soluble in acid. The ore thus prepared is then treated with sulphuric acid. This may be effected by percolation, leaching or agitation, the last mentioned being preferred. The acid is added in quantities just sufficient to take up the zinc in the ore and leave a neutral solution. This solution is then freed from solid matter by filtration or settling

and a further amount of acid added. In filtering it is desirable to filter while hot so as to keep the zinc sulphate in solution. The acid and the zinc content should be fairly high, say 140 grams of zinc per liter and from 50 to 300 grams, preferably 75 grams of free sulphuric acid per liter. The solution then is electrolyzed with insoluble anodes such as lead and any suitable cathode. The amperage should be from 50 to 300 amp. per square foot. Usually the electrolysis is conducted until 60 grams of the zinc have been removed from the solution. The solution is then regenerated by dividing it into two portions such that one portion contains as much free acid as the whole of the original solution did before electrolysis. One portion of the solution is then kept separate while the other portion is used for dissolving fresh ore until it is again neutral. This solution, after filtering, is added to the portion kept separate bringing the whole solution up to standard conditions again. During the preparation of the solution iron is precipitated by the last amount of ore added to it to bring it to neutrality. This eliminates to a marked extent the accumulation of iron salts in the electrolyte. The quality of the metal deposited under these conditions, it is claimed, is very good and may be used directly as a galvanizing coating for the protection of iron against corrosion. If zinc is desired in the form of solid metal the cathodes must be of such a nature as to permit their stripping. The zinc then may be detached, melted and cast. If zinc sheet cathodes are used no stripping is required. (1,210,017, Dec. 26, 1916.)

Gold and Silver

Flotation and Cyanidation Combined.—HARRY LOUIS FRIBERGER, of Eureka, Kan., has patented the separation of the cyanicides by means of flotation before these have any detrimental action on the cyanide solution. To the ore, ground to the required fineness and mixed with the cyanide solution, a frothing medium is added. This latter is prepared by dissolving a resinous substance, such as rosin, in alcohol, the amount of rosin used being 25 and 50 per cent of the amount of alcohol used. To this solution is then added an amount of alkaline hydrate, best caustic soda, until the solution is neutralized. From this liquid the alcohol is distilled off and reused. The product left will be either liquid, semi-liquid or solid according to the amount of alcohol left in the product. The residue is soluble in water and acts as a satisfactory frothing medium. A typical example is given in the patent. The process as a whole is simply a combination of the regular cyaniding practice and flotation. Any practical type of machinery may be used. It is claimed that this practice gives a recovery of 90 per cent of the gold and 85 per cent of the silver. Often 95 per cent of the copper and as high as 80 per cent of the lead are floated. (1,224,917, May 8, 1917.)

Treatment of Refractory Auriferous Ores.—JOHN HENRY NIEMANN, of Adelaide, South Australia, has patented an improved method of economically extracting, separating and recovering the precious metal constituents of refractory auriferous ores containing selenium or seleniferous material yielding a salt or compound of selenium. Briefly the method consists in treating auriferous ores with a weak cyanide solution in the presence of seleniferous material under non-oxidizing conditions. The gold is then precipitated from the solution in slimes in a non-oxidizing atmosphere. The slimes are distilled to recover values other than gold and the gold residues are retorted under reducing conditions. (1,222,789, April 17, 1917.)

Alloys

Bearing Metal.—HENRY K. SANDELL of Chicago, Ill., has patented an improved bearing-metal alloy. The alloy consists of copper and antimony, in substantially the proportion of two parts by weight of the former to one of the latter, together with a small proportion of lead, and preferably in addition thereto a percentage of nickel. In general it appears that the antimony possesses the property of crystallizing the copper, thereby greatly increasing the hardness of the alloy and lowering the frictional resistance. The nickel toughens the alloy by binding together the highly crystalline mass, increasing thus the tensile strength and preventing disintegration under abrasive action. A typical alloy for supporting the steel shaft of a 10-kw. dynamo running 1800 r.p.m. would be, in parts of metal used, copper 4, antimony 2, lead 1 and nickel 1. It is claimed that alloys of this type will permit a bearing to run for an indefinite period without lubrication and without showing substantial wear. The alloy shows no overheating tendency, does not itself score or score the shaft and is in all respects satisfactory for use as a bearing-bushing operating under sliding friction, either without lubrication or with very little lubrication at moderate bearing pressure and high speeds. (1,223,001, April 17, 1917.)

Uranium

Uranium.—Two patents granted to CHARLES L. PARSONS, chief chemist of the Bureau of Mines, and dedicated for the free use of the people, have been granted for a process for the purifying of uranium compounds and for preparing oxides of uranium.

The process for the preparing of uranium oxide enables pure black oxide of uranium to be obtained for the use of producing ferro-uranium. Experiments in the production of uranium steel itself are now under way. By the use of the processes above mentioned the production of pure oxide of uranium is claimed to be very much facilitated and cheapened. Also the product is obtained in a much purer form than has ever been acquired heretofore. Uranium oxide so obtained is also valuable for coloring glass, giving to glass the golden yellow color seen in some of the newer forms of automobile headlights. The chief claims of the first patent (1,224,013) are as follows:

1. The process of preparing uranium dioxid, consisting in reducing a uranium compound in a fused bath with carbonaceous matter.

2. The process of preparing uranium dioxid, consisting in fusing a mixture of a uranium compound and a flux in the presence of carbonaceous material.

(6) The process of preparing uranium dioxid, consisting in fusing a mixture of finely divided alkali metal uranate, flux and carbonaceous matter, cooling, dissolving out soluble matter and washing the residue.

(7) The process of preparing uranium dioxid consisting in fusing a mixture of a uranate and a flux in the presence of a reducing agent, dissolving out soluble matter, washing successively with an alkali solution, water and an acid.

The chief claims of the second patent (1,224,014) are as follows:

1. The process of purifying uranium compounds, which consists in fusing the same with a flux incapable of forming a soluble compound with the uranium and then dissolving out the soluble matter.

2. The process of purifying uranates from vanadium and the like, consisting in fusing the uranate with a flux incapable of forming a soluble compound with the uranium, dissolving out the soluble matter and washing the residue.

(4) The process of purifying an alkali metal uranate, consisting in fusing the same with an alkali metal chlorid, and washing the resulting mass.

Organic Electrolysis

Electrolysis of Organic Compounds.—In order to minimize the disturbing effect of the inactive electrode in electrolyzing organic solutions, Dr. Alfred Piguet, of Basel, Switzerland, proposes to prevent the emulsion from reaching this electrode. The patent is assigned to the Society of Chemical Industry, of Basel, Switzerland. The result is obtained by reason of the difference in specific gravity of the electrolyte and of the specific gravity of the organic compound to be electrolyzed. If care is taken in choosing the difference in these specific gravities, sufficiently great, it is stated to be easy to produce a good emulsion in the neighborhood of the active electrode without the emulsion reaching the other electrode. An example of this method is given in the reduction of nitrobenzene to azobenzene, which is described as follows:

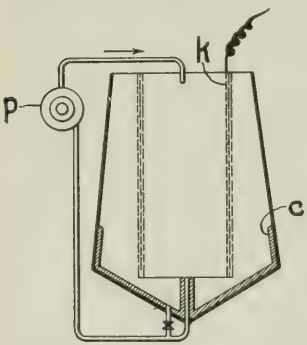

FIG. 3—ELECTROLYTIC CELL FOR ORGANIC SOLUTIONS.

"Into the middle part of a vessel of iron, having the form of a truncated cone (Fig. 3), which serves also as anode and has a conical bottom lined with a layer of cement *c*, is placed a cylinder *k* formed by several layers of iron-wire trellis acting also as cathode. The whole apparatus is filled up with soda lye of 2 to 5 per cent and with nitrobenzene, which latter sinks to the bottom of the recipient by reason of its higher specific gravity. A small rotatory pump *p* turning at a high speed causes the formation of the emulsion and the slow circulation through the cylindrical cathode. At the bottom of the vessel collects a mixture of azobenzene and nitrobenzene, which is maintained continuously in circulation by the pump. The reduction is achieved when all nitrobenzene has disappeared. The electrolysis is effected with 10 amp. per square decimeter and 2.5 to 3 volts at 85 to 95 deg. C."

Other processes mentioned are, preparation of hydrazobenzene from azobenzene, preparation of hydrazobenzene from nitrobenzene, preparation of hydrazotoluene, and oxidation of isoborneol to camphor. (1,225,052, May 8, 1917.)

Interesting Uses of Magnetic Separator Pulleys

Magnetic separator pulleys have been put to work in an increasingly large number of industries during the past 10 years. They are useful wherever it is desired to continuously remove the magnetic content from non-magnetic bulk material. For example, they are used with success in removing pickheads, coupling pins, etc., from coal passing to a crusher which would be damaged by the entrance of such material. They are used for similar purposes at phosphate rock mines and quarries. In the production of sulphite fibre paper stock, they are used to remove tramp iron and steel from the wood chips before these are delivered to the sulphite tanks. They are also used in the production of cement, gypsum, limestone, clay for terra cotta manufacture, as well as in the freeing of grain, spices and tobacco from bits of iron or steel before grinding. They also find employment in city refuse disposed plants, for removing tin cans, horse shoes, nails, etc., from the worthless material.

An example of an interesting application is found in the sugar industry, an industry in which it would seem there would be no need for such equipment. Magnetic separators made by the Cutler-Hammer Manufacturing Co., Milwaukee, Wis., and known as C-H magnetic separators are in use in a large number of sugar plants, a report on the use in one, the Revere Sugar Refining Co. plant, giving an idea of the work done in this industry.

The separator in this plant is installed to remove iron rust or iron oxide from animal charcoal which is collected by it while passing through the ovens and being baked. This baking process is necessary to eliminate from the charcoal the impurities which it has absorbed from the sugar. The magnetic material is especially prevalent after the retort has been repaired. Under ordinary conditions the magnetic pulley is energized only part of the time, two weeks out of a month or so, this being sufficient to keep the iron oxide out of the bone charcoal so that trouble with iron coloring in the sugar is prevented.

The magnetic pulley in this installation is placed in the delivery end of the conveyor which carries the animal charcoal from the retorts to the elevator. The material from which the iron content is to be removed is carried about 1 in. deep on the belt, the separator pulley revolving at about 50 r.p.m. and handling 5000 cu. ft. of charcoal in 24 hours.

The use of powdered or pulverized fuel has been

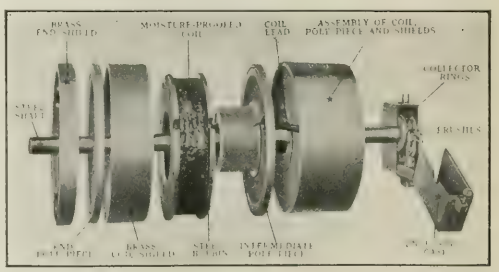

FIG. 1—EXPLODED VIEW OF C-H MAGNETIC SEPARATOR PULLEY.

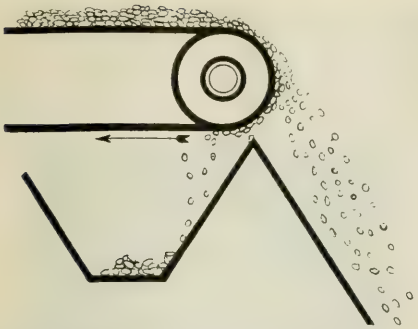

FIG. 2.—PRINCIPLE OF MAGNETIC SEPARATOR PULLEYS.

extended and this has led to the need of magnetic separators in cement plants, steel plants, powerhouses and many other kinds of plants. For open hearth furnaces, a brief mention is made here of the process of furnishing the pulverized coal and the use of the magnetic separator.

First the tramp iron is removed from the coal by means of magnetic separators. Coal as delivered to the milling plant always contains an astonishing amount of tramp iron in the form of bolts, nuts, rivets, nails, bar iron, railroad spikes, mule shoes, etc. Any of these materials entering the crusher or pulverizer might result in damage to the machine, with consequent delays in operation.

This foreign magnetic material can be entirely eliminated by the use of a magnetic separator located at some point ahead of the crusher. When the material passes over the above pulley which contains the magnet, the magnetic material, consisting of tramp iron, is attracted and held firmly against the belt and remains in contact with the belt until it leaves the magnetized zone, which is at some point beyond the under side of the magnetic pulley. The tramp iron drops from the belt after it leaves the pulley and is delivered to suitable boxes by means of a chute, the coal continuing on its course.

The shortage of natural gas caused the Missouri, Kansas & Texas Railroad to decide upon pulverized fuel for the water tube boilers in the powerhouse of the shops at Parsons, Kan. The equipment for pulverizing and drying fuel is contained in a separate building, which is located near one end of the boiler house, and the coal is dumped from the cars directly into a concrete track hopper adjoining this building. The plant is designed to handle either mine run or slack coal and immediately below the track hopper is placed a set of rolls, which reduce lumps up to 12 in. by 18 in. to 5-in. cubes or less in one operation. As the coal passes through this crusher it drops onto a belt conveyor, which discharges directly into a set of corrugated rolls. The upper end of the belt conveyor passes over a 24-in. by 22-in. Cutler-Hammer magnetic separator pulley, the function of which is to remove any pieces of iron or steel which may be in the coal and retain them on the belt until the latter passes off the underside of the pulley, the metal then dropping to the floor behind the crusher. This crusher reduces the coal to pass through a ¾-in. mesh or less and delivers it into a dust-tight elevator, from which it is distributed into a storage bin.

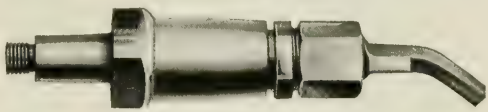
Furnishing powdered coal as a locomotive fuel by the Santa Fe made necessary a crushing plant and magnetic separator at Marceline, Mo. Here the coal (mine screenings) is fed through a drier, at the discharge end of which there is located a separator which takes out any tramp iron which may be in the coal.

The pulley is magnetized by passing direct current through the windings in the interior of the pulley.

Oxy-Acetylene Rivet Cutting

For cutting off rivet heads and stay-bolts flush with plates by the oxy-acetylene process, it is desirable to have a cutting tip so designed as to permit of the gas jet playing parallel with the plates.

To meet this need The Prest-O-Lite Company, Inc., of Indianapolis, Ind., is manufacturing a special rivet and stay-bolt cutting attachment. This attachment is



RIVET CUTTING ATTACHMENT.

used in connection with the Type K cutting blow-pipe shown, being screwed into the head in place of the regular cutting nozzles. The copper tip is bent at a convenient angle and is adjustable to any position, facilitating operation in close quarters.

Much cleaner work in rivet and stay-bolt cutting is possible with this attachment than with standard cutting tips which do not permit of a cut truly parallel with the plates.

Personal

Mr. **Francis B. Coyle**, metallurgist for the New Departure Manufacturing Company, Bristol, Conn., has resigned to assume new duties as metallurgical engineer for the Greenfield Tap & Die Corporation, Greenfield, Mass.

Mr. **J. R. Flannery** of Pittsburgh, Pa., president of the American Vanadian Company and the American Flexible Boat Company, has gone to Washington, D. C., to work with Henry P. Davison of J. P. Morgan & Co. on problems connected with the American Red Cross.

Messrs. **Ainslie Gray** and **Charles Benjamin** announce that they have formed a partnership, to be known as Gray & Benjamin, to act as advertising counsel to manufacturers of electrical, mechanical, chemical and kindred products. Their office will be in the Transportation Building, 608 South Dearborn Street, Chicago. Mr. Gray was formerly managing editor of *Electrical Review and Western Electrician*, and has been president of the Associated Business Papers, Inc. Mr. Benjamin was the first editor of *Printers' Ink*, and from 1906 to 1915 was advertising manager of the Cutler-Hammer Manufacturing Company of Milwaukee, Wis.

Frederic DeP. Hone & Co., engineers, announce the removal of their office to 13-21 Park Row, New York City.

Mr. **Philip N. Moore**, president of the American Institute of Mining Engineers, has completed visits to

several of the Western sections of the society and has returned to St. Louis.

Mr. **Louis Rasmussen** has resigned as superintendent of the Wisconsin Aluminum Foundry Company, Manitowoc, Wis., to take up other duties in Marshalltown, Iowa. He was tendered a banquet by the officers and employees of the company.

Dr. **A. W. Schorger,** who for seven years has been connected with the Forest Products Laboratory, Madison, Wis., has resigned to take charge of organic chemistry with the C. F. Burgess Laboratories at Madison, Wis. The Burgess Laboratories are actively engaged at present upon problems of national preparedness and defense, and are represented on both national and state committees. Dr. Schorger's immediate duties will be in connection with some of these problems, especially those relating to foodstuffs.

Mr. **H. N. Stronck** has been appointed vice-president and managing engineer of the Illinois Engineering, Auditing & Public Relations Company, 122 South Michigan Avenue, Chicago, this firm being successors to Benedict, Boyle & Stronck, Inc., and is engaged in general consulting business on engineering, construction, industrial economics, public relations, accounting and auditing.

Mr. **Maurice R. Thompson** of the Power and Mining Department, General Electric Company, Schenectady, N. Y., spent May and June at the new electrolytic zinc plant of the Judge Mining & Smelting Company at Park City, Utah. He will return to Schenectady via Butte, Great Falls and Trail, B. C.

Mr. **R. E. Vandruff,** president of the New Dominion Copper Company, was recently at Globe, Ariz., inspecting the properties of the company.

Mr. **John B. Wise,** superintendent of the electrolytic and acid plant of the Chile Exploration Company, Chuquicamata, Chile, will be in the United States on his vacation from June 15 to Sept. 15 of this year.

Book Review

The Mining Manual and Mining Year Book, 1917. By **Walter R. Skinner.** 960 pages. Price 15s., net. Post free; outside of England 17s., net. London: Walter R. Skinner.

This is the thirty-first consecutive yearly issue of this valuable handbook of mining companies, engineers and directors. The work includes all mines whose shares are dealt in on the London Stock Exchange and many others, including many of the large American companies. The number of companies listed is 1710 and a supplementary list gives references to former volumes on 2286 additional companies. All the regular features of the work are included. In the preface a review is given of conditions throughout the world during the past year. The previous high standard of this book is maintained in this issue, and it should prove of great value to those who wish to be well informed on foreign mining.

Obituary

Alois von Isakovics, the well known proprietor of the Synfleur Scientific Laboratories, passed away at his home in Monticello, N. Y., on June 4. Mr. von Isakovics was born at Prague, Austria, in 1870, and came to this country when he was about sixteen years old. After he had been here several years he founded the Herbene Chemical Co., in Harlem. In 1895 he married Mary Upschur, whose home was in the Southern States. In 1904 he went to Monticello, N. Y., where he founded the Syn-

THE LATE ALOIS VON ISAKOVICS

fleur Scientific Laboratories. The business flourished and the company became very well known in the manufacture of perfumes, flavoring extracts, essential oils, and other chemicals. Mr. von Isakovics was a prominent member of the Perfumers' Association and was formerly active in the American Electrochemical Society. He delivered many lectures before the chemical and pharmaceutical classes in several of the large universities.

Edward R. Taylor, the distinguished inventor of the continuous electric furnace process for the manufacture of carbon bisulphide and one of the pioneers of electrochemistry in this country, passed away at his home in Penn Yan, N. Y., on May 28. Mr. Taylor was born in

THE LATE EDWARD R. TAYLOR

St. Lawrence County, New York, in 1844, and was educated in England and America. He graduated from the Lawrence Scientific School of Harvard University in 1868. He was a professor of chemistry at the Homeopathic Hospital College in Cleveland from 1869-73, and chemist with the Cleveland Rolling Mill Company from 1869-76. He was president of the Taylor Chemical Company in Penn Yan for many years, relinquishing it a few years ago to his son, Dr. Charles Taylor. The manufacture of carbon bisulphide was commenced about 1899.

Mr. Taylor was a member of the American Electrochemical Society, American Chemical Society, American Institute of Chemical Engineers, Society of Chemical Industry and American Institute of Electrical Engineers.

CURRENT MARKET REPORTS

The Iron and Steel Market

The character of the steel market has changed entirely in the past few weeks, fully attaining the development that was referred to briefly in our last report. The business being done is of considerably smaller volume than even a fortnight ago, and is of much smaller volume than that of a few months ago. The character is altogether altered, as the buying is chiefly for what may be called early deliveries, in that they are earlier than most of the large mills can make as they are already filled with other business. The buying for distant deliveries, what came to be known last year as "delivery at mill convenience" has become inconsequential, and there are no market prices quotable. As a result, the only market that is quotable becomes the market for the earlier deliveries, in from three to six months, roughly speaking. Such prices are higher than would rule for the later deliveries, if there were such prices, and thus by a change in the nomenclature, or in the "argument" as the astronomer would put it, the market appears to have advanced more than it really has.

Prices currently quoted as representing the market are, for instance, 8c. to 9c. for blue annealed and black sheets, 4.25c. or 4.50c. for merchant bars and structural shapes, 8c. to 9c. for tank plate, and so on. These are the prices ruling on such business as is being done, but the business is largely of the emergency character. There is not represented, in the buying, any considerable amount of new construction, of car building, and the like. It is a market that cannot be maintained indefinitely unless an extremely large part of the steel output is diverted to war purposes, and of course at reasonable prices as provided by law for Government purchases. The rank and file of consumers cannot continue to do business if they must eventually pay the prices now quoted as the market.

The steel market, however, can get along for quite a while without a break, because the great bulk of the steel being shipped is invoiced at prices much below the current market. Striking an average of the various finished steel products, steel that was bought on the first of last October, and some undelivered steel was bought before that, was $50 a ton below the present market, while steel bought on Feb. 1, the date of the German submarine announcement, was about $36 below the present market.

The United States Steel Corporation has total tonnage obligations on its books, although variously distributed in the different departments, equal to its total output for about nine and a half months. The independents as a whole are booked to a somewhat smaller proportion of their capacity. As the Government places orders for steel, to be given precedence, and to the extent of 25 per cent, 40 per cent, or possibly even more of the output, the time in which the existing orders can be filled will be greatly lengthened.

Without doubt there is a slowing down in the consumption of steel. Building engagements have almost ceased. Even in May the fabricated steel contracts taken by the Bridge Builders' and Structural Society represented only 56½ per cent of the fabricating capacity. Railroad buying has practically ceased. Some of the automobile makers have materially curtailed their specifications for steel, with prospects of greater curtailment. Ford and a few others are, however, requiring more steel than they expected.

There is a great deal of newspaper talk about prices to be paid by the Government for steel, but the actual negotiations are very quietly conducted and the facts may never be fully known. The subject has been greatly confused by making comparisons of possible prices for the Government with prices now ruling on small lots for early delivery, paid by distressed buyers. It would be no strain whatever to the steel industry for the Government prices to be very much lower than the present quoted which are altogether fictitious as representing a real and broad market.

THE PIG IRON ADVANCE

At the time of last report the pig iron market was advancing wildly. It has since been advancing more conservatively, but still rather steadily, say at the rate of $1 to $2 per ton per week instead of $2 to $5. The $50 mark has been passed in some districts and not in others. The buying has been checked to a considerable extent as buyers realize the great risks incurred in purchasing for the first half of 1918, and there is little business left to be done for the remainder of this year.

The peculiar feature of the situation is that with pig iron at more than double the price it has reached in a third of a century there are some blast furnaces that are losing money, because they are still delivering pig iron sold last August and September at $18 and thereabouts, when costs have mounted very sharply, particularly because furnace coke must frequently be bought for spot shipment, to eke out the insufficient deliveries on contracts. Thus the blast furnaces have their future before them.

Non-Ferrous Metal Market

Monday, June 25.—There is practically no change in the copper market, pending Government developments. Tin has advanced during the last few weeks and lead remains strong. Spelter has been dull and antimony declined slightly. Silver has been strong and has advanced again.

Copper.—There is practically no change in the copper market and prompt electrolytic still rules around 32.50 cents with Lake at 31.00 to 31.50. A member of the Council of National Defense has stated that the Government ought not to pay more than 20 cents for copper but no definite action has been taken on the Government price as yet. It is understood that the Fed-

eral Trade Commission intends to make an investigation of the cost of producing copper.

Tin.—Straits tin has been scarce for prompt delivery and advanced from 60.75 on June 11 to 64.00 cents on June 19. It has since fallen off to 63.50. No special developments have been noted.

Spelter.—The spelter market has been characterized by its usual dulness and prices remain virtually unchanged. Prompt spelter has sold for 9.30 to 9.55 cents and these prices have remained steady during the last two weeks.

Lead.—The trust price of lead remains at 11.00 cents, New York, with the outside market asking 11.75 to 12.00 cents. The Government has purchased 8600 tons for which it is said to have paid 8 cents, St. Louis. The Government is expected to require 100,000 tons per year.

Other Metals.—Aluminium is unchanged at 59.00 to 61.00 cents for No. 1 Virgin. The Aluminium Company of America has offered to supply the Government at 27.50 cents per pound. Antimony has declined from 20.25 to 19.25 cents for spot. Magnesium can be had at 2.00 to 2.50 per pound. Quicksilver is $80 to $82. Platinum is $105, cobalt, $1.70 and silver 78½. Tungsten concentrates are $20.00-$22.00.

Chemical Market

Benzol.—Stocks of prompt benzol have generally been more than sufficient to answer the requirements of the trade but consumers have not been inclined to take hold to any great extent. Prices have held fairly well although they rule lower for the interval. Contracts are now available at attractive prices.

Toluol.—One cheap lot of resale material tended to lower values during the interval but aside from this fact prices have held rather well although the volume of business transacted has not been large. At the moment of writing the market has assumed a somewhat steadier aspect.

Phenol.—A production in excess of the demand continues and the market has eased off somewhat during the interval. The general situation is unsatisfactory from every viewpoint. A small export inquiry has developed but this has not materialized any important transactions.

Naphthaline.—This product has been offered more freely and balls in particular have been in abundant supply after a scarcity of some months. Flakes have also been offered more freely. The production continues on a large scale.

Beta Naphthol.—One manufacturer who discontinued the production of this product offered considerable quantities of surplus material at low prices during interval but these sales were not necessarily a reflection of general conditions. As a matter of fact the undertone is stronger due to the sharp advance in caustic soda.

Benzoic Acid.—A very large production of this material is noted at the present time and there are probably close to twenty firms producing the material either in glass or in a larger way. The season for large buying is now at hand but prices show but little evidence of this. Offers have been made and continue to be made on a very low basis, one, in fact that can allow but little encouragement to substantial producers. Some of the benzoic acid being produced leaves much to be desired. Practically the same conditions prevail in the *benzoate of soda market.* Production is large and prices have consequently dropped sharply.

Salicylates.—A pronounced scarcity is noted for salicylic acid and the *salicylates* and prices have advanced to high levels with supplies very difficult to secure. The tendency is still higher.

Monochlorbenzol.—A larger production has resulted in very free offerings with prices at a comparatively low level. There does not appear to be any immediate indication of an advance.

Dinitrophenol.—Spot supplies have been replenished and prices have receded with trading more restricted.

Caustic soda.—The market has climbed to even a higher level than when we last reported both for spot and contract and the speculative interest has been very active. Ground caustic continues very scarce and high. *Soda ash* has remained firm and active and owing to the fact that steamship companies have been refusing the product packed in ordinary barrels, hard wood casks have been in heavy demand for this style shipping.

Barium products.—There has been important inquiry for practically all barium compounds particularly *carbonate.* A production of *chlorate of barium* is being made here for the navy.

Copper sulphate.—Blue vitriol has been quiet with comparatively unimportant business. The export movement has not been large and has been principally to France and Spain as heretofore.

Cyanides.—With the exception of the potassium salt, all *cyanides* have been weaker and slow in movement. *Potassium,* however, is scarce and high.

Acids.—The situation generally is stronger. There have been no weak sellers. *Nitric* has been particularly strong although business has not been important. *Brimstone sulphuric acid* is revealing much firmness owing to the strong position of brimstone. *Muriatic acid* is also higher and rather more active.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, JUNE 22, 1917

INDUSTRIAL

Financial, Construction and Manufacturers' News

Financial

New Companies

The Alaska-Pacific Construction Company of Portland, Ore., has been incorporated with a capital of $300,000 for the purpose of constructing and operating steam, gas and sailing vessels. The incorporators are Charles A. Burckhardt, John H. Burgard and Lawrence A. McNary.

American Oil Developing and Leasing Corporation of Wilmington, Del., has been incorporated with a capital of $500,000.

American Oil Products Company of Wilmington, Del., has been incorporated with a capital of $500,000 to acquire lands and develop same.

The American Reduction & Chemical Company of Bellair, Ohio, has been incorporated with a capital of $50,000. The incorporators are J. A. Greenfield, A. C. Beetham, James W. Stewart, C. M. Wyrick and C. H. Dankworth.

Atlas Graphite Corporation of Birmingham, Ala., has been incorporated with a capital of $125,000. The incorporators are L. H. Weller, president; C. E. Massey, vice-president; John M. Hughes, secretary-treasurer.

Aurora Foundry Company, Seattle, Wash., has been incorporated with a capital of $10,000. The incorporators are John H. Ironside and Charles Budd.

A. W. Zinc & Lead Corporation has been incorporated in Delaware with a capital of $1,000,000 to conduct a general mining business. The incorporators are Harry McDaniel, Jr., L. B. Phillips, J. B. Bailey, Dover, Del.

The Beaver Chemical Company, Inc., of New York City, N. Y., has been incorporated with a capital of $10,000 to manufacture chemicals, drugs, etc. The incorporators are H. and B. Lichtenberg, S. Fillin, 2013 Bryant Avenue, Bronx, N. Y.

Calumet Iron & Metal Company of Chicago, Ill., has been incorporated with a capital of $25,000. The incorporators are Samuel Goldberg, Henry Goldberg, Benjamin Friedman.

Cherokee Oil & Gas Company of Augusta, Me., has been incorporated with a capital of $1,000,000 to quarry, mine, melt, refine, prepare for market, etc., any metals, mineral substances, oil and gas.

Commonwealth Lead & Zinc Company has been incorporated in Delaware with a capital of $600,000 to acquire mining property and develop same. The incorporators are Arthur W. Britton, Louis H. Gunther, Harry B. Davis, New York City.

Connecticut Steel Corporation of Bridgeport, Conn., has been incorporated with a capital of $20,000 to carry on business of every kind of manufacturing of metal and metal articles. The incorporators are William S. Lane and Arnold W. Knauth of New York, and Cornelius C. Webster of Brooklyn, N. Y.

The Constatin Refining Company of Delaware has been incorporated with a capital of $5,000,000 to refine, store and market crude oil and by-products thereof. The incorporators are Herbert E. Latter, Henry M. Robinson, Wilmington, Del.; Clement M. Egner, Elkton, Md.

C. T. Products Corporation of New York City, N. Y., has been incorporated with a capital of $25,000 to manufacture chemicals and pharmaceutical preparations. The incorporators are J. A. Haggerty, C. C. Cooper, F. C. Peters, 120 Broadway.

Cuprite Sulphur Corporation of Delaware has been incorporated with a capital of $2,000,000 to carry on a general mining business, including that of gold, silver, sulphur, etc. The incorporators are Paul A. Zrezelman and William C. Griffith of New York, and Ernest H. Greenwood of Montclair, N. J.

Diament Oil & Gas Corporation of Buffalo, N. Y., has been incorporated with a capital of $75,000 to manufacture and deal in natural gas and petroleum products. The incorporators are R. E. Diament, J. H. Clark, M. E. Butler, all of Buffalo.

Dickerson Glue Joint Company of Grand Rapids, Mich., has been incorporated with a capital of $30,000. The incorporators are D. F. Hamilton, Glenn Dickerson and William English.

The Economy Fuel Company of Portland, Ore., has been incorporated with a capital of $20,000 to deal in real and personal property in Portland. The incorporators are Elizabeth Tipton, R. J. Streicher and Robert H. Down.

Frederick Iron & Steel Company, Frederick, Md., has been incorporated with a capital of $150,000 to manufacture, purchase, sell and otherwise deal in iron, steel, brass, copper and metals, etc. The incorporators are William A. Riddel, George M. Gittinger and Claude S. Hahn, all of Frederick.

Gilmore Manufacturing Company of New York City, N. Y., has been incorporated with a capital of $10,000 to manufacture shoe black, ink dyes, chemicals, drugs. The incorporators are Benjamin Lifshitz, Robert Scherer, Morris Lippman.

Hightower Peanut Oil Mill of Brundidge, Ala., has been incorporated with a capital of $35,000 to manufacture peanut oil.

Inspiration Zinc & Lead Company of Wilmington, Del., has been incorporated with a capital of $250,000. The incorporators are M. L. Gatchell, L. A. Irwin, Harry W. Davis, of Wilmington.

Kansas-Utah Consolidated Oil Company of Wilmington, Del., has been incorporated with a capital of $3,000,000.

Kentucky Oil & Refining Co. of Wilmington, Del., has been incorporated with a capital of $1,000,000 to acquire oil lands and develop same.

Kinney-Brennan Petroleum Company has been incorporated in Delaware with a capital of $1,000,000 to produce and market petroleum, natural gas, coal and minerals. The incorporators are F. R. Hansell, Philadelphia, Pa.; J. V. Pimm and S. C. Seymour, Camden, N. J.

Lawrence Oil Corporation, New York, N. Y., has been incorporated with a capital of $2,000,000 to acquire oil lands and to develop the same. The incorporators are Arthur W. Britton, Louis H. Gunther, Harry B. Davis, all of New York.

The Linde Air Products Company has been authorized to manufacture oxygen, nitrogen and other gases in Oregon, with a capital of $200,000.

Linden Chemical Company of Linden, N. J., has been incorporated with a capital of $125,000 to manufacture and deal in chemicals. The incorporators are Adam J. Traub, Elizabeth; Norman W. Kempf and Louis A. Kempf, Newark.

Majestic Paint Company of St. Louis, Mo., has been incorporated with a capital of $10,000 to manufacture and deal in paints, oils, etc. The incorporators are S. E. Cowan, E. A. Koenemann and E. C. Breck, George L. Zollman and Chester Chapline.

Marine Steel Company of Wilmington, Del., has been incorporated with a capital of $250,000. The incorporators are M. L. Rogers, L. A. Irwin, Harry W. Davis of Wilmington.

The Metallograph Corp. of New York City, N. Y., has been incorporated with a capital of $540,000 to manufacture and refine brass, copper and other metals. The incorporators are I. M. Berliner, F. Spungin, J. J. Cohen, 135 West 115th St., New York.

Michigan Drop Forge Company of Delaware has been incorporated with a capital of $1,800,000 to manufacture iron and steel products. The incorporators are Herbert E. Latter, Henry M. Robinson, Wilmington, Del.; Clement M. Egner, Elkton, Md.

Milliff Refining Company, of Martinez, Cal., has been incorporated with a capital of $100,000 to operate a refinery.

National Aniline and Chemical Co., Inc., West Nyack, N. Y., has been incorporated with a capital of $17,231,000 to manufacture chemicals, coal tar products. The incorporators are I. F. Stone, W. Beckers, W. N. McIlravy, 17 Battery Place, New York.

Nitro-Phospho Corporation of Richmond, Va., has been incorporated with a capital of $500,000. The incorporators are M. C. Patterson, pres., T. S. Winston, v.-pres., John Landstreet, secretary-treas.

Ohio Mold and Foundry Company of Cincinnati, Ohio, has been incorporated with a capital of $50,000. Mr. C. B. Matthews, incorporator.

The Old Spanish Copper Co. has been incorporated in Delaware with a capital of $1,000,000 to produce oil and gas and acquire land containing the same. The incorporators are G. A. Lemmon, W. C. Darlington, H. Kolb, J. F. Ringle, J. H. Derieux, all of Strang, Okla.; L. Sier, Omaha, Nebr.

The Pacific Potato Starch Company has been organized with a capital stock of $60,000, to manufacture potato starch and by-products. Incorporators of the company are J. F. Griffith, Albert Muesig, and J. A. Turner. A plant will be erected.

Palladium Paint Company of Atlanta, Ga., has been incorporated with a capital of $25,000. The incorporators are N. T. Poole, A. W. Stirling, and F. A. Quillian.

J. F. Patton & Co. of Delaware has been incorporated with a capital of $100,000 to buy and sell pulp, paper, etc. Representative J. F. Patton, 83 West 42nd St.

Republic Graphite Company of Jasper, Ala., has been incorporated with a capital of $100,000. The incorporators are John H. Bankhead, Jr., H. E. McCormack, W. A. Clark and others.

Residuum Oil and Burner Company has been incorporated in Delaware with a capital of $1,000,000 to manufacture and sell devices to facilitate combustion of oils, fuels and particularly residuum oils. The incorporators are Herbert E. Latter, Henry M. Robinson, Wilmington, Del., Clement M. Egner, Elkton, Md.

Sapo Chemical Co. of Toledo, Ohio, has been incorporated with a capital of $50,000.

Shynoff Chemical Co., Inc., of New York City, N. Y., has been incorporated with a capital of $6,000 for chemical business. The incorporators are P. Glass, S. Sussman, M. I. Price, 271 Broadway, N. Y.

Southern Ferro Alloys Co. of Knoxville, Tenn., has been incorporated with a capital of $210,000 to manufacture ferro alloys. The incorporators are J. Harry Price, W. F. Black, Geo. C. Hager and others.

Steel Works Appliance Company of Pittsburgh, Pa., has been incorporated with a capital of $5,000. The incorporators are August Gums, Stephen Buchle, Pittsburgh; J. A. Whitehouse, Carrick, Pa.

The Tool Steel Corporation of Pittsburgh, Pa., has been incorporated with a capital of $600,000. The incorporators are Robert McKnight, F. M. Neeper, A. M. Neeper, Pittsburgh, Pa.

White-Burbank Paper Co., Inc., of New York City, N. Y., has been incorporated with a capital of $50,000 to manufacture paper and wood pulp. The incorporators are L. O. White, 146 Central Park West; C. I. Hamilton, 145 West 138th St., New York City; F. W. Burbank, 1916 Albemarle Road, Brooklyn.

Wonder Paper and Fabric Company, Wilmington, Del., has been incorporated with a capital of $2,100,000. The incorporators are Herbert E. Latter, Henry M. Robinson, Clement M. Enger, Wilmington, Del.

Zobel, Stern & Campbell, Inc., New York City, N. Y., has been incorporated with a capital of $20,000 to manufacture colors and dyestuffs. The incorporators are H. E. Zobel, G. M. Campbell, B. F. Meyer, 253 Ninth St., Brooklyn, N. Y.

Capital Increases

Western Utah Copper Company of Nevada has increased its capital from $50,000 to $2,500,000. The officers are Harold R. Smoot, president, and Edwin T. Jones, secretary.

The American Gas & Incinerator Company of Vancouver, Wash., has filed amended articles of incorporation, increasing its capital stock from $30,000 to $40,000. C. R. Talbot, vice-president.

The National Electrolytic Company, Canal Basin, Niagara Falls, N. Y., manufacturer of chemicals, has increased its capital from $620,000 to $1,150,000.

Construction and Operation

Alabama

BESSEMER.—The American Tar Product Company expects to build an addition to its plant at Woodward for the manufacture of naphthaline for the making of explosives. The plant is at present turning

out creosote and other coal tar products. The new by-product ovens of the Woodward Company will furnish the product for running the naphthaline plant.

Arkansas

CAMDEN.—The Camden Foundry Company has built a new and large fireproof building of concrete and iron to replace the building recently destroyed by fire.

FORT SMITH.—S. P. Hardin and associates of Clarksburg, W. Va., and Pittsburgh, Pa., will erect a glass making plant which will cost $250,000 and employ 250 men. Two cars of window and plate glass will be manufactured per day. They expect the capacity to be doubled in a year.

TEXARKANA. — The Commercial Acid Company has just completed its new plant to replace the one burned a few months ago. The new fireproof building is of brick, concrete and galvanized iron. This building is equipped with new machinery.

Colorado

DENVER.—The Denver Steel & Iron Works will operate the largest structural steel plant in the intermountain region. It was formerly the Lowith Brothers Iron Works Company, located at West Colfax Avenue and Larimer Street, and was purchased by the Monarch Engineering Works. It will be run under the above name. They expect to produce enough structural steel to supply the entire Western territory.

Delaware

WILMINGTON.—The New Castle Leather Company will build six new additions to its plant at Eleventh and Poplar Streets. Erection of two of the structures has been commenced.

WILMINGTON.—The Otto Gas Engine Company of Philadelphia has sold its land in South Wilmington to a syndicate of Philadelphia and New Jersey capitalists. A steel plant will be erected on this property. The property includes several hundred acres along the south side of the Christiana River.

Georgia

MARIETTA.—The Glover Machine Works will have shortly, in connection with their plant, a steel foundry and forge shop. They will install an electric furnace, steam hammers, sand blast machinery, grinders, sand mixing machinery, etc. The Glover Machine Works specializes on industrial locomotives.

Idaho

LEADORE.—The Sunset Mining Company, which has recently developed enormous deposits of ore at its properties, located at Leadore, Idaho, will construct a new mill in the near future. Shipments of ore running 15 to 20 per cent lead and 8 to 12 ounces per ton continue to come in regularly. Much development work is being done and it has now been definitely determined that the 500,000 tons of milling ore which has been blocked out can be mined and put into the mill at the rate of 60 cents per ton.

Illinois

NORTH CHICAGO.—The Sexton Oil Company has opened its new factory at North Chicago, which will have an output of 300,000 gal. of oil a week without double shifts. The company makes a patented motor oil.

Indiana

TERRE HAUTE.—The Grasselli Chemical plant is expected to be in operation July 1. The plant will make spelter exclusively for the manufacture of brass and galvanizing and is claimed to be the largest of its kind in the world.

Kansas

NEODESHA. — Improvements to the amount of $300,000 will be made in the plant of the Standard Oil Company of Kansas this summer to increase the capacity for the manufacture of gasoline. Twenty stills will be added, making a total of 112, which will make it one of the largest plants in the Middle West.

Maryland

BALTIMORE.—The Baltimore Tube Company will erect a new plant, 140 by 600 ft., for the manufacture of sheet brass and copper, which will cost between $500,000 and $600,000.

BALTIMORE. — The Penn-Mary Steel Company will build a new one-story concrete copper shop, about 60 x 120 ft.

Michigan

DETROIT.—Henry Ford intends to proceed with the erection of a large blast furnace plant just outside of Detroit.

Missouri

ST. LOUIS.—The Majestic Paint Company, recently organized with a capital of $10,000 has made extensive alterations on its building at 1103 Locust Street and 402 North Eleventh Street. The company is agent for the Ohio Paint & Varnish Company of Cleveland, Ohio.

Montana

BUTTE.—The Continental Oil Company plans the construction of a plant covering a block in Valley Addition. Work will be completed during the summer.

HAVRE.—Local men who are boosting the flax fiber mill expect to have the plant in operation in the near future. A building, 50 x 50 ft., will be built. Company has been incorporated under the name of The Flax Mills Company, by F. F. Bossout, James Holland, E. C. Sweitzer, W. C. McKelvey, E. C. Carruth and C. F. Morris, with capital stock of $100,000.

New Jersey

NEWARK. — The Harrison Chemical Company has purchased waterfront property; also several buildings which are to be remodeled for its needs. This property comprises six acres at Newark Transfer, with a 300-ft. frontage on the main channel of the Passaic River, extending back 900 ft. to the tracks of the Jersey Central Railroad. This property was held at $75,000 and adjoins the plants of the Sun Oil Company and the Butterworth-Judson Company.

NEWARK.—The Alcohol Products Company will spend $75,000 on a new manufacturing plant which is to be located at the foot of Blanchard Street. It will be composed of a refinery building of brick and reinforced concrete construction, with a boiler room, and an office and laboratory building.

New York

JAMAICA BAY, LONG ISLAND.—The Corrugated Fiber Mills, Inc., purchased 5 acres together with buildings, having 70,000 sq. ft. of space, at the head of Mill Basin, Jamaica Bay, for the manufacture of paper products.

JOHNSON CITY.—Endicott, Johnson & Company have ordered the material for a new fiber board mill. This building will be started about Aug. 1, and it is expected that it will be completed in the late fall. The building will be 370 ft. in length, 250 ft. of which will be one-story and the remaining 120 ft. two stories and basement. The new plant will manufacture fiber board.

LAUREL HILL.—The General Chemical Company filed plans recently with the Building Bureau in Long Island City for a steel laboratory, 48 by 33 ft., to be erected at Washington and Laurel Hill Avenues, Laurel Hill, adjoining the company's present buildings. The laboratory will cost $6,000.

WARREN.—The Warren Oil Company intends to buy 12 acres of land on which to construct a blending plant. Improvements approximating $50,000 will be placed upon the new property.

Ohio

YOUNGSTOWN.—The Youngstown Sheet & Tube Company will erect a new steel plant for the manufacture of 84-in. plates at a cost of $2,000,000.

Oklahoma

ENID.—A contract was signed between the Southwestern Oil Corporation and the Enid Refining Company for the construction of a pipeline from the oil fields east of Enid to Enid, and the building of another refinery.

Oregon

ASTORIA.—The Standard Oil Company here has purchased a block of land on the waterfront and will expend $150,000 in construction of a thoroughly fireproof plant. F. E. Roper, of Seattle, will direct installation of the plant.

MOLLALA.—The Mollala Fire Clay Company has started work on its clay mine near Mollala. A 100 ft. tunnel is being driven, and work on the kilns will begin shortly. The company holds the only clay deposit known on the Pacific coast which will make white stoneware pottery.

Pennsylvania

CARNEGIE.—The Superior Steel Company has purchased extensive property adjoining its works, for the erection of new additions.

CORNWALL.—The Bethlehem Steel Company is reported to be planning to double the capacity of its local iron ore properties, providing a total of 80,000 tons per month.

HARRISBURG.—The Keystone Industrial Corporation, recently incorporated with capital of $1,500,000 to manufacture boilers, engines, etc., is reported to be planning for the erection of its proposed plant at Middletown. George W. McIlhenny, 25 North Thirteenth Street, and D. A. Caley, 23 North Fourth Street, are the principal incorporators of the company.

PHILADELPHIA.—The Kali Manufacturing Company is enlarging its equipment in the plant at 1406 North Front Street by installing larger motors and new machinery. The company expects to increase its manufacture of oils for the textile trade.

PHILADELPHIA.—The Gill Glass Company acquired title to two tracts in the northeast section of Philadelphia on which it will erect a large factory building.

PHILADELPHIA.—The India Refining Company, manufacturer of oils, has filed plans for alterations and improvements in its plant at Swanson and McKeon Streets to cost $2,500.

PHILADELPHIA.—The Powers-Weightman-Rosengarten Company, Ridge Avenue and Calumet Street, is planning for the erection of a one and two-story brick addition to cost about $25,000 to replace the section of its plant recently destroyed by fire.

PHILADELPHIA.—The Nice Ball Bearing Company has awarded a contract for the erection of a one and three-story addition to its plant about 170 x 320 ft., at Twenty-ninth Street and Hunting Park Avenue, to cost $175,000. William Steele & Sons Company, contractors.

PHILADELPHIA.—Fire, June 2, destroyed part of the plant of the Barrett Manufacturing Company, Tucker and Bermuda Streets, with loss estimated at $40,000.

PHILADELPHIA. — The Philadelphia Paper Company is arranging for the immediate erection of its proposed new one-story plant, about 170 x 270 ft., at Manayunk.

PHILADELPHIA. — The Pierce-Arrow Tire & Rubber Manufacturing Company, Germantown, is having plans prepared for the erection of a new plant to cost about $150,000. J. Osborn Hunt, Trenton, N. J., is architect.

PHILADELPHIA. — The Westmoreland Chemical & Color Company has filed plans for the erection of an addition to its plant on Twenty-second Street.

PHILADELPHIA.—The American Pulley Company, 4200 Wisahickon Avenue, manufacturer of pulleys, hangers, etc., will build a one-story addition, about 50 x 70 ft.

READING.—The Reading Knob Works, Oakbrook, will build a new one-story foundry addition, about 50 x 50 ft.

WARREN.—The Warren Oil Company purchased 12 acres of land lying west of Warren upon which will be built a blending plant. Improvements approximating $50,000 will be placed on the property.

Tennessee

MOUNT PLEASANT.—The Hoover & Mason Phosphate Company is building a new plant about one and a half miles from Mount Pleasant on the Mount Pleasant Southern Railroad. It will cover five acres of a 650-acre tract which contains phosphate enough to engage employment for twenty-five years. It is being built entirely of steel construction.

NASHVILLE.—The Nashville Products Co. is a new manufacturing concern located at 912 Church Street, to manufacture floor cleaners and disinfectants. The promoters are I. W. King and Henry Foster of Nashville.

Utah

SALT LAKE CITY.—The Utah Paraffine Oil & Wax Co. will erect an oil shale distillation plant for the manufacture of crude oil, paraffine wax and ammonium sulphate. The company has been experimenting for three years and will use a distillation process similar to those used on oil shales in Scotland. Mr. Lawrence Greene of Salt Lake City is president and general manager of the company and Mr. O. W. Ewing is managing director. Research work has been conducted at the University of Utah and Detroit Testing Laboratories.

Virginia

NEWPORT NEWS.—The Empire Steel Company, recently incorporated, is planning for the purchase of a local site for the installation of a large steel works. The plant is estimated to cost about $900,000, and will include steel furnaces, billet mill and auxiliary structures. The local Chamber of Commerce (J. N. Shannahan, president), is interested in the project. Joel F. Armistead, Atlanta, Ga., is head of the company.

Washington

CHEWELAH.—The Northwest Magnesite Company has completed plans for proposed development of its magnesite claims. A large crushing mill will be installed immediately, an aerial tramway built, and six rotary kilns installed, with capacity of 600 to 1000 tons daily. A big plant, costing $200,000, will be started as plans are completed. R. S. Talbot heads the concern.

IRONDALE.—After an idleness of almost five years, the blast furnace of the defunct Western Steel Corporation at Irondale, Wash., about 50 miles from Seattle, is being placed in working condition by the Pacific Coast Steel Company of Seattle, who has acquired the property. Between $75,000 and $100,000 will be expended before the furnace is ready to blow in, and the work will require sixty days' time. Engines and machinery of the plant, which has been damaged by long idleness, will be overhauled, and new equipment added at many points. Practically the only existing structure will be replaced by new buildings, the big wharf will be rebuilt, and the ore and coke elevators overhauled. Present plant has capacity of 60 tons daily, which will not be increased at present. William Piggott, president of the Steel Company.

NORTHPORT.—The Northport Smelting & Refining Company is building and equipping a plant for the treatment of smelter gas, to cost in the neighborhood of $100,000. Structure will be 75 x 150 ft., and equipped with a series of 900 pipes, to which metallic particles will be attracted electrically while suspended in the fumes. The equipment is known as the Cottrell system, and is expected to save 5 per cent of the values, and pay for itself in six months of use.

SEATTLE.—The Linde Air Products Company, a New York concern, has leased a site at Eighth Avenue South, Seattle, on which a big plant will be erected. The main building will be one-story, 130 x 282 ft., of reinforced concrete and steel, costing $300,000.

SEATTLE.—The General Basic Products Company, located at 2926 Sixteenth Avenue S. W., although organized but two years, has a modern manufacturing plant, and has developed a splendid business, both local and foreign. The plant manufactures stone cement, stucco, fireproofing materials, sanitary wall finishes, calcimine, cold water paints and Puritan Lime. The company does a large export business.

SEATTLE.—The Puget Sound Cement & Lime Company, Seattle, according to V. C. Coxhead, has leased thirty-five acres of State land near Ballard, on which it plans to build a plant for the manufacture of cement and plaster and lime.

SEATTLE.—A series of experiments by the College of Mines, University of Washington, indicates that graphite from the Seward peninsula of Alaska can be refined for commercial use, according to Joseph Daniels, Assistant Professor of Mining. Samples of graphite have been refined by the concentration process.

SEATTLE.—The American Nitrogen Products Company, Securities Building, will start work at once on additions to its nitrogen plant at La Grande, which will make the plant three times its present size. The first unit, now in operation, cost $50,000.

SPOKANE.—Oliver P. Moore, secretary-treasurer of the Washington Steel & Iron Company, has invented and patented a new oil and gas burning smelter furnace. It is a combination, consisting of a pre-heating and reduction chamber and a smelting and refining chamber.

SPOKANE. Day Brothers, owners of the Hercules Mine, are making large additions to the Wallace Mill, including installation of four tube mills, 36 Franz tables and additional jigs. The improvements are to permit of remilling the tailings for the iron, to be used at the Northport smelter.

SPOKANE.—Washington State Pharmaceutical Association will convene in Spokane on June 14, 15, 16. A. W. Linton is secretary of the association.

SPOKANE.—The Spokane-Benton County Natural Gas Company has applied to the city council for a franchise to pipe natural gas into the city, build a distribution plant which will produce 2,000,000 cu. ft. of gas daily.

SPOKANE.—The Spokane Corrugated Culvert & Tank Company, of this city, plans to immediately double the size of its factory, and extend its lines of manufacture. C. A. Mowry is secretary-treasurer and general manager. Approximately $20,000 worth of new machinery will be installed, and an addition, 100 x 100 ft., together with an office building, will be constructed.

TACOMA.—E. D. Gallaher, general manager of the American Minerals Producing Company of Tacoma, is at the head of a syndicate which proposes to develop an extensive deposit of potassium nitrate and sodium nitrate near Vale, Ore. An experimental plant will be installed at the property, which is claimed by chemists to contain nitrate of high value and tremendous quantity.

TACOMA.—Frank S. Baker, local, who is at the head of a project to install a paper mill near Tacoma, states that details for the plant are complete, and construction will begin shortly. Plant, including buildings and machinery, will cost $400,000.

West Virginia

CLARKSBURG.—The Hope Natural Gas Company will erect a gas producer plant at Downs for experimental purposes. The capacity of the plant when completed will be equal to two ordinary gas wells. The product will be used to operate the big gas producing stations and what is not used will be turned into the gas mains to experiment with the natural product. The coal to run the producer will be supplied by the Rachel Coal Company.

KANAWHA CITY.—The Libbey-Owens Sheet Glass Company and the Owens Bottle Machine Company will be in operation shortly, making an investment of $5,000,000 and will be the largest sheet glass and bottle plants in the world. These plants cover a site of 76 acres, and will employ hundreds of men. C. W. McNulty & Company of Charleston and Huntington have the contract for the general construction work at the Libbey-Owens Sheet Glass plant, while the Toledo firm of Devore-McGormley Company, industrial engineers and architects, planned the several buildings which constitute the great plant. W. J. Monaghan of Toledo, is the supervisor of the construction for the architects. The main building is to be 504 ft. in length and 396 ft. in width. In the front portion of the building six tanks have been constructed, each 72 ft. long, 20 ft. wide and 5 ft. deep and each having a capacity of 170 tons where the molten glass is made. Mr. William Jacobs of Toledo will be the manager of the plant and Arthur E. Fowle general manager.

Wisconsin

MILWAUKEE.—The Wisconsin Metal Refining Company, Fratney and Franklin Streets are occupying their new factory which is 80 by 150 ft.

ST. FRANCIS.—The Valley Forge Company of Pittsburgh, is to build a $1,000,000 steel mill at St. Francis, in Milwaukee County. The mill will be about 100 x 300 ft. of light steel frame and wood sheathing.

Wyoming

COWLEY.—The Columbia Carbon Company of New York will erect a large plant for the manufacture of carbon black at Cowley, Wyo. The carbon black will be manufactured from natural gas drawn from the wells of the Wyoming Consolidated Oil Company. The first building of the unit will be 14 ft. by 114 ft. The first unit will have 96 buildings of this dimension, which will cost $600,000.

Manufacturers' Notes

CATALOGUES AND TRADE PAPERS WANTED IN CHILE.—Commercial Attaché William F. Montavon, at Lima, Peru, recently visited the library and reading room of the Sociedad de Fomento Fabril in Santiago, Chile, an organization with headquarters in Santiago, which has for its purpose the promotion of manufacturing in Chile. The Secretary of the Sociedad de Fomento Fabril is desirous of exchanging the bulletin of its association with trade and industrial journals in the United States. The Secretary would also appreciate receiving catalogues of American manufacturers and exporters, which will be placed on file in the library and reading room. The address of the society is: "Sociedad de Fomento Fabril, Casilla 4114, Santiago, Chile."

THE ROSS POWER EQUIPMENT CO. have been appointed Indianapolis representatives for The Lincoln Electric Company of Cleveland, Ohio, and their offices are at 617 Merchants Bank Bldg., Indianapolis, Ind.

RESOURCES OF BOLIVIA ON EXHIBITION.—The Consul General of Bolivia, in the United States, announces that he has now on exhibition, at the Consulate—forty-first floor of the Woolworth Building, New York City—a part of the minerals, rubber, precious woods and other native products of the Republic of Bolivia, that were shown at the late Panama-Pacific Exposition in San Francisco. He would be pleased to receive callers to view the specimens. This exhibit will be maintained at the Consulate as a permanent feature to aid in the dissemination of information regarding opportunities in Bolivia. All inquiries should be addressed to the Secretary.

LARGE HEATING AND VENTILATING INSTALLATION. — The National Acme Company of Cleveland, Ohio, has placed an order with the Buffalo Forge Company, Buffalo, N. Y., for a large heating and ventilating equipment. The equipment consists of four Carrier type "A" air washers with automatic control and fresh and return air dampers; four Niagara Conoidal supply fans, two of which deliver 100,000 cu. ft. of air per minute each, and two 95,000 cu. ft. of air per minute each; four exhaust fans, two of which will handle 70,000 cu. ft. of air each and two 50,000 cu. ft. of air per minute each; ten Baby Conoidal fans for toilets; twenty-seven thousand sq. ft. of Vento and four 12 x 14 steam engines for driving the fans. Geo. S. Rider & Co. are the consulting engineers.

PRODUCTION OF COPPER IN 1916.—An advanced official statement of the production of copper in the United States in 1916 has been issued by the Geological Survey. The author is B. S. Butler. The smelter production of primary copper was 1,928,000,000 pounds, compared with 1,388,000,000 pounds in 1915, an increase of 39 per cent. Arizona was the largest producer again with a record of 694,847,307 pounds. Montana was second with 352,139,768 pounds, and Michigan third with 269,794,531 pounds. Utah, Alaska, New Mexico and California follow in the order named. The total production of new refined copper in 1916 was 2,259,000,000 pounds, an increase of 625,000,000 pounds over 1915. The production of secondary copper was 104,423,807 pounds. In addition to the secondary material treated by the regular refining companies, plants that treated secondary material exclusively, produced a total of about 553,000,000 pounds of copper as copper and in brass and other alloys of copper, making a total production of 662,000,000 pounds from secondary sources. Of this total at least 250,000,000 pounds was produced by remelting clean scrap produced in the manufacture of copper and brass articles.

There was also produced about 56,000,000 pounds of bluestone, averaging 23-25 per cent copper.

THE MANUFACTURE OF PHTHALIC ACID AND PHTHALIC ANHYDRIDE.—The Department of Agriculture announces that the Color Investigation Laboratory of the Bureau of Chemistry, of this Department, has perfected, on a laboratory scale, a new process for the manufacture of phthalic acid and phthalic anhydride. This process, as carried out in the laboratories, appears so promising that it is thought that some manufacture of chemicals and dyestuffs in this country may be able to supply their demands for these compounds by this process, provided the process can be reproduced upon a technical scale so as to obtain results commensurate with the laboratory investigations.

With a view to helping the chemical industry of this country, the Department of Agriculture hereby announces that it is ready to assist manufacturers who wish to produce these compounds. The expenses of the technical installation and of the labor and materials necessary will of necessity be borne by the firm, individual, or corporation who wishes to manufacture the products. The chemists of the Color Investigation Laboratory will assist with expert advice, etc. The Department reserves the right to publish all the data obtained from the technical experiments.

Since it seems very desirable that phthalic acid and phthalic anhydride be made available in large quantity in this country at the earliest possible moment, this offer of assistance will not be held open by the Department for an indefinite period.

Regulation of Iron and Steel Prices

That it would eventually become necessary for the Government to regulate prices in the iron and steel industry has been apparent for some time. There is no reason to suppose that there is any serious opposition, in the minds of the steel producers, to a wise and efficient system of regulation. Certainly no such opposition has been expressed. Some articles have been published, written by novices, suggesting difficulties, and pointing out, for instance, that if the price of this commodity were regulated and the price of that commodity were not, an injustice would be done; suggesting further that the Government needs taxes, but how can there be taxes unless there is something to tax? Purposely or otherwise they overlooked the fact that there is no efficiency in robbing Peter to pay Paul and then taxing Paul. Better tax them both—collect the revenue at the source, so to speak.

It bespeaks a rather profound ignorance of the steel trade to argue that the products are so varied that an equitable schedule could not be drawn up or adhered to. What was the experience of 1908? In time of peace, with no inspiration greater than a desire for the common good; with no obligation more than a half-expressed moral one; in fear that what they did was not approved by the Government, rather than with knowledge that the Government insisted upon their doing it; with buyers only too eager to tempt them to infractions—the steel manufacturers then maintained with considerable success a price structure that was utterly contrary to the law of supply and demand. The real force at work at the time was merely the knowledge that if the market were broken all would suffer in their profits. The price structure was well understood in 1908, and it was adhered to with sufficient faithfulness to maintain the situation for more than a year.

It will be taken for granted that there can be no regulation of the price of one commodity without regulation of the price of another, or of a finished product and not of the raw or intermediate materials. A complete structure must be built up. Fair profits should be allowed, both for the economic benefit accruing and to make certain that production shall be at the maximum, for the reason that a figure which nets a profit to one mill may be ruinous to another, poorly positioned in this or that respect.

As to the relationship in prices, the experience of the past may be taken, checked by an examination into the extent to which costs have changed. The average relationship that has obtained between various commodities,

between bars and structural shapes, for instance, are well known. The differentials for size, shape, etc., in the different lines are well established. A schedule to proportion profits between the coke producer, the blast furnace and the steel maker should not be difficult. No such schedule, certainly, would produce the inequalities, indeed the iniquities, that have obtained in the recent past.

In April, 1916, there were $45 billets with $18.50 pig iron. Afterwards the price of billets doubled while the price of pig iron tripled. One or the other alignment was wrong. In July, 1916, there was $2.65 Connellsville coke and $18 pig iron. On June 30 of the present year there was $16 coke and $54 pig iron; triple-priced pig iron and sextuple-priced coke. Early in 1915 blue annealed sheets sold at $4 a ton more than plates, and 28-gage black sheets at $10 a ton more than blue annealed sheets, all of which was in keeping with the cost of manufacture. In May and June, 1916, plates and black sheets sold at the same price while blue annealed sheets sold at $2 a ton more. Since March, 1916, wire nails have sold at a lower price per pound than the wire rods from which they are made. The keg is thrown in.

The steel industry gracefully and cheerfully, even amusedly, having "put up" with these inequalities, has no great reason to be perturbed by prospects of inequalities growing out of price regulation by the Government.

As to profits in the aggregate, the prices now quoted as representing the market are so much higher than the prices at which material was delivered in the last period for which earnings statements of the steel companies are available, that there can be no comparison. Such market as exists is practically fictitious, but it is the only market that can be quoted, and on an average the prices are fully double those at which material was being shipped in the first quarter of the year. The earnings at that time were of course quite satisfactory, seeing that they were at record rate.

The essence of price regulation, as we understand it, is to see that the ordinary buyer of steel is not penalized because the Government becomes a buyer. There can be no competition between individual and Government, as the Government sets, or will set, its own prices, but the ordinary commercial buyers would bid against each other in the effort to secure steel, and the contest would be won by the man who could boost the price the highest.

This price, in turn, would be limited only by his ability to dispose of the metal, perhaps through a long chain of "intermediates," to the ultimate consumer. The Government would collect perhaps 20 per cent of the excess profits of the steel maker, and not a red cent from the consumer of steel. Doubtless the consumer would be glad to be able to limit his liability to the aforesaid 20 per cent tax. A far better and more patriotic policy is "one price to all," neither ruinous to the individual in the purchase of his necessities, nor exorbitant to the government, that is to say, the American people, in this time of need.

Leather Substitutes

In the present issue is a short note by Andrew H. King on the making of substitutes for leather—especially as regards the manufacture of shoes. His pronouncement that, even at present, rubber soles are better than leather, and that a wholly non-leather shoe of equal utility appears to be not only a possibility, but an actuality, should be very good news to many a suffering pater familias, standing amazed at the combined efforts of his active youngsters and the no-less active shoe market. Mr. King's views in this may be taken as authoritative, inasmuch as readers of Metallurgical and Chemical Engineering will remember his recently published and masterly articles on various other phases of the rubber manufacturing industry.

The Internal Combustion Engine

To the many debts we owe the internal combustion engine—not the "interior combustible" engine, as one of the Washington correspondents recently had it—there is likely to be added, according to the military experts, the debt of its winning the war for us. The science of aviation has kept ahead of the engine that has brought the flying machine to its present stage of usefulness. At the outset, the Wright brothers were able to rise from the ground merely by giving their machine its initial acceleration by means of a weight. Going still farther back, an anecdote, now first appearing in print, may be told.

The laws of the air in relation to flight were investigated exhaustively by the late Dr. Samuel Pierpont Langley, then director of the Allegheny Observatory. The experiments, by the way, were financed largely by the late William Thaw, vice-president of the Pennsylvania Railroad Company. There are few, probably, who know that the laws governing aerial flight were given to the world through the grandfather of the Lieutenant Thaw who has won laurels in France by practising the art of which his forebear had dreamed.

But to the anecdote of the internal combustion engine: Dr. Langley's experiments were conducted chiefly by means of an "aerodrome," a horizontal structure mounted on a vertical axis. At one end of the structure various pieces of apparatus were mounted in turn, to be driven against still air, so as to record the various performances of planes and propellers. To drive the aerodrome or turntable there was provided a 5-hp. gas engine of standard make. One day it became desirable to resume the outdoor experiments, and the mechanician was instructed to start the gas engine. After a time he succeeded, and the turntable was driven at the magnificent speed of six revolutions per minute. That was not enough, and while the authorities consulted, a young assistant, still in his teens and with the surplus energy of the period, seized the handle that was provided for bringing the turntable to any desired position for adjustment purposes, and drove the turntable thirteen revolutions per minute, developing four times the power of the 5-hp. engine, if the resistance

increased as the square of the speed. An expert was then summoned, who spent half a day grinding the valves. Then the engine ran half a day and stalled. The expert wanted to spend another half-day regrinding the valves, but Dr. Langley called them all off and adopted a rusty old harvester engine that happened to be in the neighborhood.

That was the status of the internal combustion engine at the time the laws of flight were being developed. About eighteen years afterwards the Wright brothers flew. They acknowledged their debt to Langley for the laws governing flight, the world had given them the engine and they had invented their stabilizing and other devices which enabled one to fly without coming to grief. Gustav Lilienthal had had many successful "glides" without a motor before he met his death in one sixteen years before the Wright brothers flew.

Fixing Prices

Suppose we were engaged in raising potatoes. We suppose this because we have no desire to represent special interests in the matter, and we have also no intention to go into Potatocal Engineering. Let's imagine, then, that we are potato producers, and that collectively we grow spuds for the whole community. It is not a monopoly, we are rivals in business and yet potatoes are scarce. Labor is hard to obtain and wages are high. The community that supports us numbers, let us say, about fifteen thousand souls—or, rather, to keep the idea of our business in mind, fifteen thousand human stomachs. We are tenant farmers and the land all belongs to Uncle Hiram, who has stipulated in every lease that each tenant shall provide him, pro rata, with potatoes for the needs of his immediate family according to his requirement, and at his own price. We can afford to do that, especially as the old man is a bachelor and lives very simply. It is merely one of his foibles, and we count it as a negligible addition to the annual rent.

Sunday mornings after the long sermon and while the young folks are achieving merit in Sunday school, we walk around the churchyard, chew peppermint leaves and timothy stalks, and discuss potato prices. It is gossipped that one or two of the more speculative storekeepers have been bidding on the crops of certain neighbors before the harvest, and we listen with delight to the observation of some hired man who has heard tell—although he disremembers when or where—that prices for well-grown, mealy potatoes ought to reach four dollars and over a barrel by next fall. We are not accustomed to such figures; and yet, although we are not clear in our minds as to our costs, it sounds agreeable.

Then suppose something extraordinary, something utterly unexpected and undreamed of should happen: Uncle Hiram, if you please, has gone and turned Mormon; he has married a thousand wives, all of them widows, with an average of nine children each. To pile on the agony, the last, lamented husbands of Uncle Hiram's new soul mates were mostly Irish; and while you may be a little uncertain as to what an Irishman will do under given circumstances or what his politics are, there is never any question that he will endow his progeny with an appetite for potatoes. We also learn (as in a footnote) that Uncle Hiram's price for his family requirement of potatoes for 1917 is *fifty cents a barrel.*

Now we have a situation to meet that is new and bewildering to us farmers—although it may be growing familiar to the steel men, the coal producers and some others. Our crop of potatoes was a little short even for the fifteen thousand inhabitants of the community, but Uncle Hiram's addition of ten thousand more to it, and one-half of them Irish, puts us in a quandary. We do not know how many barrels of potatoes he will require, but we can guess and we can fear; and we do know the price. We cannot agree on selling values for the rest of our product because that is against the law; it would be a conspiracy in restraint of trade. Uncle Hiram, on the other hand, does not have to agree with anybody, or conspire, or do anything but make up his mind that he will pay fifty cents a barrel, and that fixes the price for him. His action is legal. So we become worried, sorely worried.

But still worse is the fix of our neighbors who are engaged in other walks of life. We have all the potatoes there are, none may be purchased elsewhere, and there are not enough to go around after Uncle Hiram's generous two-fifths have been extracted. We do not need to do anything to bring about high prices. Our neighbors bid against each other while we hold off to observe the fireworks. In the course of time the soaring prices may assuage our distress, but in that very measure there may arise trouble in the town. The incidence of competition would shift from sellers to buyers and in potatoes there would be at once a famine and a wild market, which is always an unwholesome situation.

We have no comment to make on Uncle Hiram's conversion. We desire to avoid all discussion of religion, and if his marriage to the thousand widows was an act of faith we have neither cause nor right to complain. But his price of fifty cents a barrel for his own many potatoes seems to us to work hardship upon the rest of the community. Not only are they shortened in their supply but they are called upon to pay unheard-of prices. They are crippled in their various walks of life. They are injured in business and in health and in the end they may be unable to pay rent as promptly as they did—if indeed they can pay it at all—and Uncle Hiram, who owns everything, needs rents now more than ever before.

It seems to us that it would have been better if the old gentleman had fixed his price at something nearer the market. Some of his wives might be thrifty, and feed thinner. Others might cook rice. And the community would not have to pay so much to us very much frightened farmers, who, being particularly anxious to cover our expenses lost in the deliveries to Uncle Hiram's step-flock, would err on the side of caution.

Magnetic Separation of Tungsten Ores

To the Editor of Metallurgical & Chemical Engineering

Sir:—In your June 1 issue, page 632, mention is made under "Some Uses of Magnetic Separators," that magnetic separation is not used in the Netherland District of Colorado for the treatment of tungsten ore.

As the undersigned is perfectly familiar with conditions in that locality, he wishes to advise you that this is not literally true, as hundreds of tons of these tungsten concentrates and middlings are annually treated over the Wetherill magnetic separator. In some cases concentrates have been increased from 40 to 65 and 70 per cent tungstic acid, and where pyrite is associated with ferberite, magnetic separation is indispensable.

A large three-magnet separator of the Wetherill type is at present operating in Boulder.

During the last three or four months the writer has tested hundreds of tungsten ores magnetically and success was obtained on practically all of them. It was proven that the magnetic separation was a commercial success and in several instances the only salvation in saving the values.

In the garnetiferous scheelite ores of Nevada and California, difficulty of separating garnets from scheelite was encountered by wet concentrating methods. The trouble is obviated by the use of the Wetherill magnetic separators which have eliminated all of the garnets and raised the grade from 10 to 25 per cent. Considering the present high bonus for purity, magnetic separation speaks for itself.

Guayule Rubber

To the Editor of Metallurgical & Chemical Engineering

Sir:—With reference to the article by Andrew H. King on "Guayule," in your issue of Nov. 15, 1916, and on "Rubber Planting," in your issue of Jan. 15, 1917, the following notes from my experiences may be of interest.

In November, 1904, I operated at Torreon, Mexico, the first plant extracting rubber from guayule by mechanical means, as per my U. S. patent No. 779,696, Jan. 10, 1905, Mexican patent No. 4079, Oct. 22, 1904. This was the birth of the guayule industry. Several smaller concerns, established later, paid royalties, but the more important ones infringed upon my patent rights.

Several years ago I visited the University of Arizona, at Tucson, and there saw an experiment in progress with growing about ½ acre Guayule. These plants were subjected to irrigation. I called their attention to the fact that most of the plants in sight were Mariola instead of Guayule, but I noticed several well and perfectly-formed guayule plants, and therefore came to the conclusion that Guayule can be grown successfully.

Over five years ago I prepared addresses on "Rubber Planting in the United States." I repeat what I then stated, that Guayule and Landolphia, "the creeper," having rubber in threads within the bark, can be grown in many sections of California, on lime formations, close to transportation, and purchasable at $2 to $4 per acre. I am informed that the Intercontinental Rubber Co. are planting an extensive tract with Guayule in Arizona. Excessive heat, drought, or cold is not detrimental to Guayule. It is a winter plant, and the International Rubber Co. is following a sound pursuit. There are ways to plant from the seed at a nominal cost; the advantage of planting shoots is that it results in a year's saving in the time necessary before it becomes of sufficient size for use.

Latex-holding Florubanda, a creeper holding a fair quality of rubber, and Chitte trees, such as are abundant on the west coast of Mexico, producing rubber, can be sown in California. There also exist in Utah or Idaho "Indian Roots," and in California a "Rattlesnake shrub," which grows abundantly, 4 to 10 ft. high, and contains 3 to 4 per cent rubber.

There never need be a scarcity of good quality hard rubber in the United States, as such can be produced to perfection by pulverizing any rubber-containing shrub, adding thereto sulphur (or in some instances litharge) and vulcanizing the mass. I hold patents on this process, but owing to the cheap compounds being used at present the advantages I offer are meager.

Coming Meetings and Events

American Chemical Society, Boston, Sept. 10-15, 1917.

Third National Exposition of Chemical Industries, Grand Central Palace, New York, week of Sept. 24, 1917.

American Institute of Metals and Foundrymen's Association, Boston, week of Sept. 24, 1917.

American Electrochemical Society, autumn meeting, Pittsburgh, Oct. 3-6, 1917.

American Institute of Mining Engineers, annual meeting, St. Louis, Oct. 8-13, 1917.

Western Metallurgical Field

Molybdenum

According to an article by E. P. Grant, in the Bulletin of the Canadian Institute, June, 1917, the International Molybdenite Co. treated 2350 tons of ore containing approximately 60,000 lb. of MoS_2 at their various plants. The ores were shipped from properties in Ontario, Quebec, and British Columbia, about half of the total tonnage treated being custom ores, while the rest came from the company's own properties. The ores from the different localities are dissimilar in character, some containing iron sulphides in large amounts and some being very micaceous. The ores from British Columbia seem to be freer from deleterious substances than those from Ontario and Quebec, although the flakes of molybdenite are very much smaller, and in some instances are nearly amorphous.

The ores are treated at the concentrator at Renfrew, which was completed in September, 1916, by a process developed after eighteen months' experimentation. On entering, the ore goes to a jaw crusher, thence to a

gyratory crusher, and thence either to storage bins or to a rotary drier. The flow up to this point is effected by gravity. The material is then raised to the top of the mill, where it is delivered to a large set of rolls and screens, the undersize dropping on a conveyor belt leading to storage bins in the flotation department. The oversize is raised by a bucket elevator to a second set of rolls and screens, the undersize again being sent to the storage bins in the flotation department. With ores containing large flakes of molybdenite a fairly good concentrate may be obtained by proper screening practice. As a rule, this concentrate is taken to sampling rolls to be cleaned, while the undersize goes to the flotation department. An automatic sampler is placed immediately below the gyratory crusher, and the bulk sample thus produced is reduced to an assay sample in the usual manner.

The flotation department adjoins the mill, and is housed in a building 90 ft. long by 30 ft. wide. It contains nine flotation machines, 6 ft. wide by 18 ft. long. The chutes from the storage bins mentioned above are 12 ft. above the floor level, and discharge into a traveling hopper of 1200 lb. capacity, and which in turn discharges into 2400-lb. hoppers feeding the flotation machines. The material discharges from the feed hoppers through adjustable openings to the feed boards of the flotation machines. The flotation machines have a capacity varying from 500 to 1500 lb. per hour, depending upon the character of the material treated, the finer the material the lower the capacity. The size of material floated also varies with the nature of the ore. Usually, a product through 20 mesh gives satisfactory results, but it has been found necessary at times to crush some ores through a 60-mesh screen. The concentrate is collected at the end of the machine, dried on steam driers, and is then ready for shipment; or, if low grade, is given a special treatment. The tailing is carried to the dump by means of waste water.

It has been demonstrated that it is most economical to produce a product ranging between 60 per cent and 70 per cent MoS_2, and this is therefore the company's aim. The mill was designed to handle 100 tons of ore per day but at present its capacity is from 50 to 60 tons. The following table gives an idea of the percentage extraction. The tonnage put through was small and the extraction a little above normal.

Day	Lb. Floated	Per Cent MoS_2 in Heads	Per Cent MoS_2 in Tails	Per Cent Recovery
Oct. 17	23,400	2.29	0.24	90
	22,200	1.16	0.17	90
Oct. 18	15,000	1.64	0.16	90
	19,800	1.66	0.21	87
Oct. 19	28,800	1.35	0.26	80
	28,800	1.71	0.49	71
Oct. 20	28,200	1.74	0.24	86
	20,400	1.37	0.31	80

The concentrate from the mill is shipped to the company's refinery at Orillia, which produces ferro-molybdenum, molybdic acid, and ammonium molybdate of both commercially and chemically pure quality. The first stage of the process is to convert the concentrate into crude ammonium molybdate. This is then charged into an electric furnace with the requisite amount of iron. The furnace department has a capacity of two tons of ferro-molybdenum per 24 hours. The furnace product contains 70 per cent to 76 per cent metallic molybdenum, less than 0.1 per cent sulphur, no phosphorus, no copper and about 3 per cent carbon. All the ferro-molybdenum produced at present is sold to the Imperial Munitions Board.

The chemical department produces molybdic acid (85 per cent and 99 per cent), and ammonium molybdate. At present only the chemically pure materials are made. Some research work has been done in this department in connection with producing molybdenum dyes and molybdenum wire. The chemically pure molybdic acid and ammonium molybdate are supplied for laboratory purposes to Canada and the United States.

The company produced ferro-molybdenum, molybdic acid and ammonium molybdate valued at $110,000 in the year ending on Dec. 31, 1916. However, these figures are not representative of actual operations as ferro-molybdenum has only been produced since October, 1916. At present the production will amount to $500,000 per annum, and is increasing rapidly. These statements are of interest, as this concern is unique as being one which mines and purchases molybdenum ores, operates its own concentrator, uses its own process of concentration, refines all the products from its concentrator, and at the same time produces chemically pure reagents.

Labor Troubles

The whole Rocky Mountain district seems to be having an epidemic of strikes. None of these concern a very large body of men, but rather are local infections of rather limited extent. The operations of all allied industries, however, may be seriously curtailed by the strike of a few electricians or engineers. On the other hand, internal dissensions among the unionists over jurisdictional or other rights are a prolific cause of trouble. In their entirety it seems probable that a large decrease in metal production will result.

The Colorado Mill Operators' Association

A new society of the above name has been organized, and held its first regular meeting on June 30, at the Brown Palace Hotel, Denver, Col., presided over by the president, Judge E. A. Colburn. The society was organized with the hope that other States might follow the lead, also forming such associations, all of them interested in milling practice, which will then unite, becoming a strong and efficient national organization, which, as a whole, will be capable to consider matters of national import in the field of milling. Mr. G. L. Nye, H. C. Colburn and J. M. McClave presented interesting papers on flotation, while J. M. Hyde discussed informally the recent decision in the suit of the Minerals Separation Limited vs. Hyde. Mr. J. F. Collbreath, secretary of the American Mining Congress, also spoke on the work of his organization.

Recent Development in the Missouri, Kansas and Oklahoma Zinc Fields

The most noteworthy developments are the strikes made in the Miami field. Quite a few mills in the Webb City and Carterville districts are now being dismantled and are being shipped into the Kansas and Oklahoma fields. The price of blende at present being $75.00 for the highest grade, ranging down to $60.00 for second and third grades, makes it rather hard for the producers in the Webb City and Carterville fields to produce blends profitably. This is also true of some of the South Joplin Mines, since the average cost of mining and milling in these dis-

tricts is from $68.00 to $75.00 per ton of blende. However, there are quite a few mills operating in the older fields, some are fairly profitable and some are merely hanging on, but the operations are gradually being reduced to the better producers.

The ores in the Miami district, while very rich, are not quite so freely liberated as the ores in the Joplin fields, requiring a finer grinding.

The adoption of table concentration in preference to the old-fashioned sand jig, is very noticeable in the entire district, while flotation is gradually but surely coming. Several small installations are floating their ores and several larger mills are under construction. The flotation concentrates, however, are causing difficulties, particularly those from the Miami field, where the lead in the original ore is often quite high. As is commonly the case with most complex ores and particularly with ores from the Joplin district, lead is concentrated in the finer sizes. For this reason the flotation concentrate may contain from 10 to 20 per cent lead with a zinc content of 40 to 45 per cent, which naturally requires a subsequent separation of lead and zinc. Of course the smelters do not favor an extremely fine concentrate, and as a whole, this particular type of product will require some new metallurgical treatment.

One concern in Webb City is now conducting extensive research work on the manufacture of zinc dust, and has produced some dust showing a precipitating efficiency of 75 per cent working on silver cyanide solutions. This might open a welcome outlet for some of the flotation concentrate which at present is otherwise not very desirable.

Flotation

Although only a few years old, the flotation process has risen to be the main system for concentrating ores. According to Prof. Francis A. Thomson the flotation plants of America are handling 30,000,000 tons of ore each year, while the world's capacity is 50,000,000 tons. Flotation leads all other methods of treatment in America, as is shown in the following table:

Method	Tons Per Year
Flotation	30,000,000
Copper smelting	26,000,000
Gravity concentration	25,000,000
Gold and silver milling	13,000,000
Lead smelting	5,500,000
Copper leaching	2,000,000
Zinc smelting	1,000,000

Approximately the same ratios apply to the world production, except that the proportion treated by copper smelters will be less and by gold mills greater than here given. It would be easier to enumerate ores which are *not* being floated than to list the other category. Gold, silver, copper, lead, zinc, molybdenum, cinnabar, tungsten and many other ores are being successfully handled, and it is proposed to use the process for the recovery of substances as far apart as flour-gold and anthracite coal. It looks as if there may be keen competition between cyanidation and flotation in the treatment of gold and silver ores during the next few years, with the odds apparently in favor of cyanide for gold and of flotation for silver.

It is only natural that a process which has arisen to such eminence in the short space of six years should excite universal interest among miners, millmen and metallurgists, not to mention the legal profession. The very evident ease and economy with which it makes very difficult separations commends it to the practical mill man, while its unexplained modus operandi irresistably attracts the scientific metallurgist to its mysteries.

Unfortunately, the progress of the flotation process has been marred by unending litigation between the owners of a number of the basic patents and various concentrating mills who have either wittingly or unwittingly committed infringements. It is notorious that a very large percentage of mill operators have assumed an openly hostile attitude toward the Minerals Separation Company which is unfortunate in the extreme, but which they aver is entirely due to "bulldozing" and other "armstrong" methods of the holding company. It is a matter of universal regret that it seems impossible to suppress recrimination leading even to actual war during the development of this process, which has such wonderful potentialities.

Company Reports

1916 Report of Camp Bird Limited.—During the year 26,237 tons (wet weight) of ore were treated at the stamp mill and at the cyaniding plant. This tonnage yielded $791,749.55, an average of $30.92 per ton, as compared with $29.47 for last year. The running-time in both mills was 331 days, 1 hour, 50 minutes, based on a maximum of 25 stamps dropping for 24 hours per day until the 11th of May, and beginning May 12th a maximum of 20 stamps dropping 8 hours per day until the 24th of June, when 20 stamps started dropping 24 hours. There was a saving of 97.13 per cent of the gold in the crude ore, and a saving of 95.19 per cent in the combined value of gold and silver. Of the total value extracted, 63.88 per cent was extracted by amalgamation, 31.63 per cent by concentration and 4.49 per cent by cyanidation.

Annual Report of the Utah Copper Company for 1916.—The total quantity of ore milled at the Magna Plant was 6,143,500 tons, being an increase of 910,200 tons as compared with 1915. At the Arthur Plant 4,850,000 tons of ore were milled.

The average grade of ore treated at both plants was 1.435 per cent copper as compared with 1.434 per cent copper for 1915. The average recovery at both mills was 62.34 per cent, corresponding to 17.90 pounds of copper per ton of ore, as compared with 64.13 per cent, or 18.39 pounds of copper per ton for the previous year. The low extraction is mainly due to the large tonnage of ore treated, and in small part to the presence of unrecoverable carbonates.

The cost of milling at the Magna Plant was 35.35 cents per ton and at the Arthur Plant 40.94 cents per ton as compared with 30.91 cents and 39.02 cents, respectively for the year 1915. The average cost of milling at both plants was 37.82 cents per ton as compared with 34.02 cents for 1915. The increased cost was due to higher costs of labor and supplies. In fact, the cost per ton should have been considerably lower than the cost for the previous year on account of the greater tonnage treated.

The total gross production of copper contained in concentrates was 196,752,631 pounds, and the average grade of concentrates was 18.71 per cent copper. The corresponding figures for 1915 were: Copper in con-

centrates, 156,207,376 pounds; concentrates contained 19.17 per cent copper. The copper contained in direct smelting ores amounted to 664,849 pounds. The value of gold and silver recovered from the copper amounted to 0.653 cents per pound of copper treated.

During the course of the year the feeders and conveyors in the coarse crushing department of the Magna Plant were remodelled. The feeders in the fine crushing department of the same plant were also changed. At the Arthur Plant, the electric sub-station was remodelled, some new equipment for the foundry was purchased and the main tunnel for tailings and concentrate launders was enlarged. Near the end of the second quarter, designs were sufficiently advanced to start construction upon the additional equipment for the purpose of improving recoveries, and increasing the capacity of the mills. Three of the thirteen sections of the Arthur Plant were practically remodeled before the end of the year but were not put in operation, due to unavoidable delays in the receipt of some parts of the equipment. Similar improvements will be continued at this plant and started at the Magna Plant. The improvements consist principally in adding to the fine grinding and concentrating equipment. When completed it is expected that the combined capacity of the plants will be 40,000 tons per day, of which the Arthur Plant will handle 16,000 tons and the Magna Plant 24,000 tons.

Construction work on a new leaching plant was started early in August, 1916. It is contemplated to construct 12 concrete leaching tanks. The twelve tanks will have a capacity of from 3000 to 4000 tons per day. The plant is so situated and planned that its capacity can readily be increased to 10,000 tons daily. The material to be treated at this plant consists of the oxidized and partially oxidized capping overlying the sulphide ore bodies. It is estimated that 40,000,000 tons of this material will be available for treatment. The copper content of this oxidized ore body is estimated at 13 pounds per ton of ore. Experiments indicate that about 10 pounds of the copper content is soluble in dilute sulphuric acid. Results of tests show that approximately 9 pounds of copper can be recovered from one ton of capping. The net cost of treatment will amount to about 9 cents per pound of copper recovered.

The Engineering Council

On June 27 the first meeting of the Engineering Council was held. This body is a department of the United Engineering Society and has recently come into being as a medium of co-operation between four national engineering societies. The function of the Council may perhaps best be described by the following extract from the by-laws of the United Engineering Society: "The Council may speak authoritatively for all member societies on all public questions of a common interest or concern to engineers."

The Council is composed of twenty-four members, five being appointed by each of the four founder societies and four by the United Engineering Society. Its present membership follows:

American Society of Civil Engineers.—J. F. Stevens, (Chas. Warren Hunt), George F. Swain, F. H. Newell, Alex. C. Humphreys, F. D. Galloway.

American Institute of Mining Engineers.—P. N. Moore, S. J. Jennings, B. B. Lawrence, J. Parke Channing, Edwin Ludlow.

American Society of Mechanical Engineers.—I. N. Hollis, Chas. Whiting Baker, John H. Barr, A. M. Greene, Jr., D. S. Jacobus.

American Institute of Electrical Engineers.—H. W. Buck, E. W. Rice, N. A. Carle, P. Junkersfeld, C. E. Skinner.

United Engineering Society.—Clemens Herschel, B. B. Thayer, I. E. Moultrop, Calvert Townley.

At the organization meeting held in the rooms of the American Society of Mechanical Engineers on June 27 the following officers were elected:

President, I. N. Hollis; Vice-Presidents, H. W. Buck, George F. Swain; Secretary, Calvert Townley; Executive Committee, the four officers named with J. Parke Channing and D. S. Jacobus.

The council discussed at length ways and means by which the founder societies through the Council may be of use to the nation. The unanimous desire to help the Government in the prosecution of this war resulted in a resolution instructing the executive committee to co-operate with the government in procuring the services of engineers, also the appointment of a committee of three consisting of Messrs. H. W. Buck, A. M. Greene, Jr., and Edmund B. Kirby, to consider the best means of utilizing the inventive ability of members of the founder societies.

The secretary was instructed to inform all Government Bureaus that might be interested in the organization of the Engineering Council and its desire to be of assistance.

St. Louis Meeting of the American Institute of Mining Engineers

Oklahoma Oil Fields

Those attending the annual meeting of the American Institute of Mining Engineers will be interested in viewing, among other things, the enormous development

VIEW OF GLENN POOL FIELD NEAR NEW TANEKA, SAID TO BE THE WORLD'S LARGEST OIL FIELD

of the oil resources of Oklahoma. The magnitude of the operations springing up almost over night may be realized by the accompanying view in the Glenn Pool Field.

Work of the Council of National Defense

The first official comprehensive statement of the organization and accomplishments of the Council of National Defense and its Advisory Commission was incorporated in a report from the Director of the Council and Advisory Commission, Mr. W. S. Gifford, to the chairman of the Council, Secretary of War Baker. The length of the report (48 typewritten pages) is indicative of the enormous amount of work accomplished. The great value of the accomplishments to date can be gathered from the introductory statement giving a brief summary of the work as follows:

The mobilization of the 262,000 miles of railroads of the country for the Government's defense.

The close-knit organization of the telephone and telegraph companies of America to insure to the Government the most rapid and efficient wire communications.

The settlement of the recent threatened national railroad strikes.

The very general acceptance by labor and capital of the suggestion of the Council that existing labor standards should not be changed until the need for such action had been determined by the Council with the steadying influence on industry growing out of such action.

The procurement of 45,000,000 lb. of copper for the uses of the Army and Navy of the United States at less than one-half of the then current market price—a saving to the Government of approximately $10,000,000.

Similar accomplishments as to steel, zinc and aluminum.

The completion of the inventory, for military purposes, of 27,000 American manufacturing plants.

The money saving to the Government, through appointment over the country of committees of business men to assist the quartermasters' department of the Army in the economical and efficient purchase of supplies.

The saving to the Government of millions of dollars by the proper co-ordination of purchases through the agency of the General Munitions Board of the Council of National Defense.

The creation, under the medical section of the Council, of a General Medical Board, consisting of many of the most highly qualified surgeons and physicians of the country.

The selection by the same section of thousands of doctors specifically qualified for membership in the medical officers reserve corps, and the standardization, far on its way to completion, of surgical instruments and supplies.

The creation by the Council of the Aircraft Production Board, which is setting out to make 3500 airplanes and to train 8000 aviators this year.

The very definite results obtained by the Council's Committee on Coal Production in the procurement and expeditious shipment of coal, both in the civilian and federal interests.

The successful initiation of a movement to co-ordinate activities on the part of the States of the Union for the national defense, brought to a clear and workable focus by the conference of States held recently in Washington at the call and under the auspices of the Council.

The organization of a railroad committee to send to Russia; and

The enlistment of reserve engineer regiments to aid in rehabilitating the railroads of France.

A list of the members of the Council and its Advisory Commission, and of the various sub-committees, was given in our issue of June 1, 1917, page 633.

General Munitions Board.—On April 9, 1917, the General Munitions Board began its work under orders of the Council. The chairman of this board is Frank A. Scott, vice-president of the Warner & Swasey Co. The board has co-ordinated the department buying of the Army and Navy in order to avoid competition in the various departments. It has made investigations and recommendations and drawn up contract forms in the purchase and manufacture of small arms, artillery, gun forgings, gun carriages, shells, cotton duck, raw materials, etc. It has also advised on cantonment work, optical glass for military instruments and gages. It has made adjustments with the British Government and compiled statistics of manufacturers. It has saved the Government considerable money through the co-ordination of purchasing.

Munitions Standards Board.—This board was created on March 20, 1917, by the Council.

Careful investigations have been made and meetings held with manufacturers of shells, machine guns, etc., with resulting introduction of modifications in specifications and design to permit of greater quantity of production. A comprehensive list of manufacturing concerns who had been and were manufacturing munitions for the Allies was compiled for confidential use and the productive capacity of the country along these lines was developed and tabulated.

Aircraft Production Board.—This board was organized to advise on design, specifications, standardization and production of aircraft and to co-operate with the Army and Navy in furthering the science of aviation. The board has worked on training plans, has assisted in starting schools, has adjusted the patent situation, investigated production facilities, developed plans for making training planes and battle planes and considerable other work. It is pushing the production of aeroplanes as fast as possible.

Inventions (Naval Consulting Board of the United States).—The Naval Consulting Board of the United States, headed by Thomas A. Edison and composed of eminent scientists and inventors, acts as a board of inventions for the Council of National Defense. The board is now, and has been for some time, actively engaged in the investigations of plans to counteract the submarine menace.

Commercial Economy Board.—The duties of this board, under the chairmanship of A. W. Shaw, are to ascertain how commercial business may best meet demands made upon it by the war, and how men, supplies and equipments now employed in trade can be made available for the needs of the Government without impairing the essential services of trade and without unnecessary hardships to the public at large.

The board is investigating retail delivery service, economies in trade and manufacturing, such as wrapping, packing, the effect of diversion of certain raw materials to the production of military supplies, etc.

Committee on Coal Production.—This committee, recently formed, has been active in strike difficulties,

transportation problems and Government and domestic supplies.

National Research Council.—At the request of the Council of National Defense the National Research Council is maintaining in Washington an active committee under the direction of Dr. George E. Hale and Dr. R. A. Millikan for the purpose of co-operating with the Council of National Defense in matters pertaining to scientific research for the national defense. The chairman of the Chemistry Committee of the Council is Dr. M. T. Bogert, who also has his office in Washington.

The National Research Council is at present engaged in such investigations as the study of devices for detecting completely submerged submarines and mines; range finders of various types; devices for detecting invisible aircraft and sapping parties; improvements in wireless apparatus and other instruments used with aircraft; military photography, prevention of corrosion and electrolytic action on the hulls of vessels; balloon fabrics; fabrics for army slickers; new explosives; and utilization of wastes and by-products. The committee on nitrate supply appointed at the request of the Secretary of War to consider the process to be used by the Government in its plant for producing nitrates for explosives and fertilizers, has submitted a full report. Through the co-operation of the Bureau of Standards and the geophysical laboratory of the Carnegie Institute with glass manufacturers, the problem of supplying the optical glass for military purposes is well advanced toward solution. Another vital matter which is being fully investigated is the study of noxious gases and methods of protection. Committees of or associated with the Advisory Commission, viz.: Committees on Transportation and Communication, Telephone and Telegraph, Supplies, Raw Materials, Minerals and Metals, Labor, Munitions and Manufacturing, Engineering and Education are all doing noteworthy work. The details of some of this will be given in a later issue. Lack of space prevents its publication here.

American Society for Testing Materials

Annual Meeting at Atlantic City, June 26-30, 1917

Undoubtedly the most important paper presented at the meetings of the American Society for Testing Materials, of which the first day's proceedings were reported in our preceding issue (this volume, page 11)—was that by Dr. **Charles W. Burrows** of the United States Bureau of Standards. He had been working for some time to determine whether there was a relationship between some easily-determined magnetic or electrical property of the metal with its homogeneity or constancy of physical properties. He now says that "the fundamental fact that there is a definite relation between the magnetic and mechanical properties of steel is so well established that the successful application of magnetic analysis to commercial testing is assured." He admits that apparatus for the particular case must be developed and operators trained, but "the difficulties presented are not excessive."

It is planned to publish this paper in a subsequent issue, and further comment is reserved until that time.

A subcommittee prepared tentative specifications which may be regarded as useful suggestions to metallurgists and microscopists in general, on proper **metallographic practice.** Their recommendations for this work are as follows:

The standard magnifications for making micrographs of steel and ferrous materials should be: 50, 100, 250 and 500 times, and for non-ferrous metals should be 25, 75, 150 and 250 times.

For general use in society reports and for showing the grain size of ferrous materials use a magnification of 100 diameters, and of copper and copper alloys, 75 diameters. Reproductions of micrographs in publications should be made of the exact standard magnifications. If micrographs submitted for publication are not, they should be enlarged or reduced to the nearest standard size, and should be printed in the form of squares in order to conserve space. With each micrograph should be printed an explanatory title, together with actual magnification, etching medium, treatment, etc., indicating what the author intends to show, so that it will not be necessary to search the text for general information.

Magnifications	Lens	Ocular
20 to 50	Microplaner or microtessar	None
30 to 70	32 mm.	Huyghenian ocular x5
75 to 150	16 mm.	Huyghenian ocular x5
250 to 500	Apochromatic 4 mm.	Projection ocular

All objectives should be corrected for uncovered objects, and the bellows extension regulated to give the exact magnification desired. It should be borne in mind, however, that increasing the magnification by increasing the length of the camera bellows adds nothing to the detail of the micrograph. This depends entirely upon the resolving power of the objective used.

Important suggestions as to the determination of grain size are as follows:

(*a*) *Alloys consisting of but one type of crystals* (*e. g.*, copper, alpha brass, etc.): In counting individual grains the original crystal, including the twinned layers, should be called one grain.

(*b*) *Alloys consisting of two metallographic components* (*e. g.*, steels, Muntz metal, etc.): The original grain which has given rise to the aggregation of the two components should be taken as the unit when determinable, and the individual component in other cases. When grain size is included in actual specifications, the term should always be defined.

For measuring grain size, two methods are recommended, depending upon the condition of the material:

(*a*) *For material in which the grains are equi-axed* (*e. g.*, most metals in the cast and in the annealed state): The planimetric method as modified by Jeffries is recommended for use as being very accurate and rapid. It is recommended that the circular area used should always include at least 50 grains.

(*b*) *When the grains are not equi-axed* (*e. g.*, in strained materials): Heyn's intercept method should be used, the average grain size being determined by counting the number of grains at a given magnification along a line of known length on two axes at right angles to each other, one axis being parallel to the direction of rolling. In some cases a third count along a line perpendicular to the other two may be desirable. This will necessitate the preparation of another polished surface.

The grain size as determined by the plani metric method should be expressed as the number of grains

per unit area (square inch or square centimeter). This may also, but less preferably, be expressed as the average grain area; or the average linear dimension of the grain may be given. The grain size as determined by the intercept method should be expressed by giving the average number of grains per linear unit in the two directions; or the average number per unit area together with the ratio of length to breadth of grain (L/B) may be given.

If grain size is to be included in specifications, it should be expressed as the maximum or minimum allowable as determined above. It is recommended that only in extreme cases should grain size be made the sole basis of rejection of material.

In the discussion of the report, it was pointed out by **George F. Comstock,** Titanium Alloy Mfg. Co., Niagara Falls, N. Y., that there should be separate standards for ferrous and non-ferrous metals and emphasized that 75 diameters, though possibly applicable to *rolled* nonferrous material, was not satisfactory for *cast* nonferrous material. Objection to the scale of magnifications recommended was made on the basis that the scales obtainable with many commercial pieces of apparatus, modified to suit the proposed standard of 50, 100, 250 or 500, would in some cases result in loss of definition or in others unnecessarily limit the field photographed.

The ever present question of **corrosion** was again up for consideration. During the discussion, Mr. **R. B. Carnahan,** Jr., second vice-president American Rolling Mill Co., Middletown, Ohio, deplored the lack of a real measure of corrosion. A metal roof is removed because of a few leaky holes, though many parts of it show no corrosion at all. To describe corrosion in terms of a loss of weight in an accelerated test is fallacious. The failure of a steel plate in spots may be due, he held, to flaws resulting from steel cast in a dirty or moist mold, from some malpractice in the soaking pit, from seams produced in rolling; and many of these mill influences may be worse than chemical shortcomings.

Mr. **W. R. Webster** submitted a short illustrated paper showing the lack of connection between interior surface defects on brass condenser tubes and corrosion therein. It is the belief of some engineers that defects on the interior surfaces of brass condenser tubes act to accelerate corrosion and that accordingly their presence even to a small degree should not be tolerated. Extended observation on the part of the author has failed to furnish a basis for such a belief. It has been found that tubes containing such interior defects are no more subject to corrosion than those which were free from them.

It has further been observed that there is no tendency whatever for areas of corrosion to localize in the vicinity of such defects. Moreover, many cases have been found in which severe pitting had occurred in the vicinity of such defects, but absolutely no tendency of the corroded areas to follow along the lines of defect has ever been noticed.

A recent case of severe corrosion was observed which furnishes very strong evidence that no such connection exists. The tubes had been in service in the condenser of a large stationary plant for about six months and then removed because of perforations caused by local corrosion on their interior surfaces. Of a lot of eleven tubes, eight were found to be absolutely free from surface defects in the vicinity of the corroded areas.

Particular attention was called to the fact that even where a corroded area crosses a defect, no tendency whatever for the corrosion to follow the defect is observable. In most of the samples the corroded area was confined to a distance not over 4 in. from the inlet end of the tube, the remainder of the tube being as free therefrom as when first made.

H. A. Gardner, assistant director of the Institute of Industrial Research, read a paper describing a series of exposure tests which were made on paints applied to large-size metal plates, 24 by 36 in., with the object of determining what grade of pigment is best suited for use as a priming coat.

After three years' exposure, the panels to which had been applied a single coat of red lead containing a substantial percentage of litharge were in better condition than the panels painted with a single coat of highly oxidized red leads or iron-oxide paints. Those portions of the panels to which had been applied two coats of paint, gave substantially the same relative results.

The paints used were reserved, examined and analyzed after storage for three years. The highly oxidized red leads in general were not in superior condition to the others, except in one instance where a red lead of low specific gravity was used. The other paints were soft and in excellent condition.

Much has been said regarding the hardening of red lead in packages, especially if the red lead should contain any pronounced percentage of litharge. It is interesting to record the condition of the paints used in these tests after standing for three years in half-gallon cans. When the cans were opened, some of the clear oil was removed from each package and ashed to determine the amount of pigment that had gone into solution. The results of the tests indicate that red leads high in lead tetroxide are quite as soluble in linseed oil as red leads high in lead monoxide.

The results obtained in the storage tests indicate that some chemical action takes place other than that to be accounted for by the formation of lead linoleate, since the latter is soft rather than hard. The writer is of the opinion that the chemical reactions which are partly responsible for the hardening of red-lead paints, cause the formation of lead glycerinate, a substance that is recognized as one of the hardest and most durable cementing materials. It is obvious, therefore, that linseed oil having a high acid number and often containing a substantial amount of free glycerin is dangerous to use in making red-lead paints that are to remain in packages for a long period previous to use.

Noteworthy papers which might also be mentioned were "A Method for Studying the Effects of Temperature Upon the Physical Condition of Asphalts, Waxes, Etc.," by **J. A. Capp** and **F. A. Hull;** "Determination of Absolute Viscosity by the Saybolt Universal and Engler Viscosimeters," by **Winslow H. Herschel;** "Light Versus Heavy Reductions in Cold-Working Brass," by **W. Reuben Webster.**

The Committee C-8 on "Refractories" presented a very interesting report on the testing of refractory materials under load at high temperatures, and on testing the slagging action of refractories. **C. E. Nesbitt** and **M. L. Bell** presented a paper on "Some Suggested Improvements in the Manufacture of Silica Brick," all of which we hope to publish in extenso in a following issue.

The Action of Aluminium Chloride on Pure Aromatic Hydrocarbons[1]

By Robert J. Moore and Gustav Egloff

Contributon from the Havemeyer Chemical Laboratory, Columbia University, No. 298.

In a general study of the formation of benzene and toluene resulting from the action of temperature and pressure upon paraffin,[2] naphthene[3] and aromatic[4] base oils, it seemed desirable to work out the action of aluminium chloride upon pure aromatic compounds with a view to determining the yields of benzene and toluene, this information then to be applied to commercial sources which would contain in large quantity the aromatics studied. The aromatics studied for this preliminary information with respect to the course of reaction were benzene, toluene, xylenes, cumene and cymene.

A review of the literature indicated a number of reaction products resulting from the action of aluminium chloride upon pure aromatic hydrocarbons, but there was no report of the percentage yields of benzene and toluene resulting. The following communication covers the percentage yields of benzene and toluene resulting from the action of aluminium chloride upon the aromatics studied, benzene, toluene, xylene, cumene and cymene.

HISTORICAL REVIEW OF THE LITERATURE

It is well known that the action of methylchloride and aluminium chloride upon benzene builds up higher methyl derivatives of benzene. Ador and Rilliet[5] by passing methylchloride in the presence of benzene and aluminium chloride showed that the reaction took place as follows:

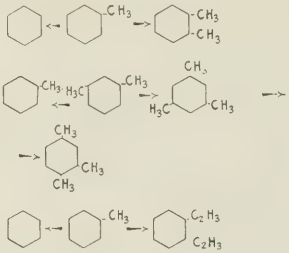
Jacobsen[6] a few years later carried the methylation of benzene much further in the presence of aluminium chloride. He was able to replace each hydrogen atom of the benzene ring by a methyl group clear to hexamethylbenzene. He found the course of reaction to be as follows:

benzene → toluene → xylene (o) (m) (p) { mesitylene / pseudocumene } → { durene / isodurene }

→ pentamethylbenzene → hexamethylbenzene

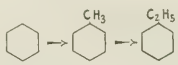
If reversibility of the reaction is assumed, the splitting off of alkyl groups from a benzene nucleus and the building up of higher homologs of benzene should be readily accomplished. But the decomposition products resulting from the action of aluminium chloride upon benzene and its alkyl derivatives are much more complex than such as would result from the simple transposition of alkyl radicals, for polycyclic compounds have been isolated which could have been formed only by the rupture of the benzene ring with the formation of pentacyclic substances of the picene type.

Anschütz and Immerdorff[7] gave in 1884 a note upon the course of reaction when toluene, (m) xylene and ethylbenzene were treated with aluminium chloride as follows:



The mechanism of the reaction is explained by assuming a simple migration of the alkyl radical from one phenyl group to another. Friedel and Crafts[8] upon heating naphthalene and aluminium chloride from 100 deg. C. to 160 deg. C. found that benzene, hydronaphthalenes, and hydrogenated isodinaphthyl were formed in the reaction.

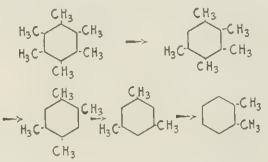
Upon testing further the effect of aluminium chloride on benzene[9] and toluene at a temperature between 180 deg. and 200 deg. C. they concluded that the reaction took place in the direction of:



They noted that ethylbenzene resulted from toluene, which fact was not observed by Anschütz and Immerdorff.

In contradiction to Anschütz and Immerdorff, Friedel and Crafts stated that the reaction is much more complex than a simple migration of alkyl groups.

No theoretical discussion of the course of the reaction was attempted by either group of investigators. In treating hexamethylbenzene with aluminium chloride Friedel and Crafts[10] gave the reaction direction as:



They made the important observation that a gas was given off during the reaction of greater molecular weight than either methane or ethane and which was not absorbable in bromine, indicating paraffin formation. No exhaustive study has as yet been made as to the composition of the gases resulting from the action of aluminium chloride upon aromatic hydrocarbons.

At the boiling point temperature little action took place between the reagent and benzene, but upon increasing the temperature to 180 and 200 deg. C. in a sealed tube the principal resulting products were found to be toluene, ethylbenzene and diphenyl. Toluene

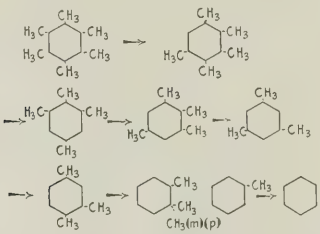
heated under similar conditions gave as products xylene, ethylbenzene and perhaps ditolyl. From the ultimate analysis and the boiling point, ditolyl seemed to have been formed. They were also able to isolate phenols which were probably formed from the oxygen of the air in the system, acting upon the aromatics in the presence of the aluminium chloride.

Jacobsen[11] in 1885 built up durene from mesitylene by the Friedel and Crafts' reaction. He asked the question, "Is it either a splitting off of a methyl group from the hydrocarbon, which unites with the mesitylene and forms (m) xylene, and perhaps first pseudocumene and then durene? Or are penta and hexa methylbenzene first built and then methyl groups splitting off, giving durene?"

The well-known synthetic reaction of benzene and methyl chloride in the presence of aluminium chloride gives:

from which he reasoned that the reverse should be possible:

He treated hexamethylbenzene with one-half its weight of aluminium chloride at a temperature between 190 deg. and 200 deg. C. From analysis of the reaction liquid he recovered in large part:



Likewise carrying the tests with pentamethylbenzene, pseudocumene, mesitylene and (m)xylene the course of the methylation or migration of the methyl radical took place as follows:

hexamethylbenzene ← PENTAMETHYLBENZENE → durene / isodurene

pentamethylbenzene ← durene / isodurene ← PSEUDOCUMENE → xylene → toluene → benzene

durene / isodurene ← pseudocumene ← MESITYLENE → xylene → toluene → benzene

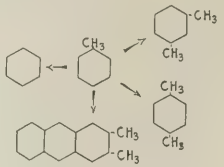
durene ← pseudocumene ← METAXYLENE → toluene → benzene

In all the reactions carried on by Jacobsen methylchloride was formed and he argued that the higher homologs of benzene resulted from the transposition of the methyl group.

A comprehensive investigation was carried out by Anschütz[12] in 1885 as to the action of aluminium chloride upon aromatic hydrocarbons. He selected for his investigation toluene, (m)xylene, pseudocumene, ethylbenzene and cymene. He heated toluene for three hours in a sealed tube with 30 per cent of aluminium chloride. The reaction liquid was fractionated and the distillate boiling between 79 deg. and 85 deg. C. gave a specific gravity of 0.8805 at 20 deg. C.

[11]Berichte 18, 338, 1885.
[12]Annalen 235, 179, 1886.

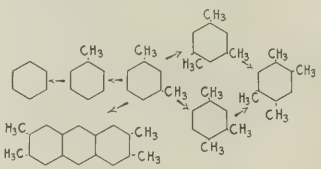
This fraction was nitrated and the benzene identified as dinitrobenzene; (m) and (p) xylene were isolated from the cut 135 to 144 deg. C. *No* (o)xylene was isolated and he concluded that it was not formed. A hydrocarbon solid was isolated which by Jacobsen's[13] method analyzed as dimethylanthracene. The course of the reaction from toluene was as follows:



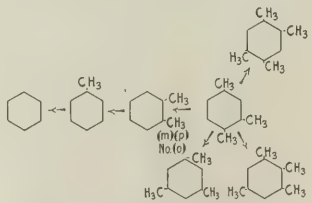
Metaxylene was heated with 25 to 30 per cent of aluminium chloride. The benzene formed was isolated in the cut from 80 deg. to 90 deg. C. and identified as the dinitrobenzene. The toluene was nitrated from the cut of 110 deg. to 114 deg. C. and isolated as trinitrotoluene. The 135 to 144 deg. C. fraction yielded metaxylene as the trinitro product with a melting point of 175 deg. C. and the para as the oxidized paratoluic acid and then to the terephthallic methyl ester. Mesitylene was analyzed by the Fittig and Wackenroder[14] method as the trinitromesitylene with a m.p. of 232 deg. C. The pseudocumene was isolated as the trinitroproduct with a m.p. of 185 deg. C. by a method devised by Jacobsen.[15]

Durene was isolated and identified by a method devised by Ador and Riliet.[16] There was isolated from the residue a hydrocarbon which seemed to be tetramethylanthracene with a m.p. of 290 deg. C.

The products isolated from metaxylene probably took the following course:



Pseudocumene gave the following compounds when treated with aluminium chloride: toluene, meta and paraxylene, mesitylene, durene and isodurene.

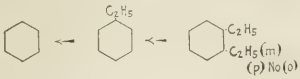


They stated that a syrupy mass of liquid remained in the flask as a residue and probably contained anthracene compounds, but was not investigated further.

Ethylbenzene reacted similarly to metaxylene in forming *no* ortho diethyl compound of benzene. Toluene

[13]Berichte 10. 1009. Ibid 11, 17.
[14]Annalen 151, 93, 295.
[15]Annalen 184, 179.
[16]Berichte 12, 331.

formed *no* ortho product of xylene. This seems to indicate that there may be some protective action of aluminium chloride in shielding the ortho position.



A residue was left in the flask which was a heavy black mass and was not investigated further.

Heating cymene with aluminium chloride gave a violent reaction and upon analysis of the reaction liquid gave mainly toluene. This would indicate that a splitting off of an isopropyl group resulted and not a migration over to another phenyl group, to form di or tri isopropyl derivatives of benzene. It seems likely that the reaction became exothermic and carried the reaction beyond the stability of the isopropyl compounds. Carrying out the reaction at a low temperature would yield entirely different results as to the migration theory of the Friedel and Crafts reaction.

Heise and Töhl[17] by passing hydrogen chloride through a solution of aluminium chloride and isopropylbenzene found that an isopropyl group would migrate to another phenyl radical. They found that the reaction products were propane, benzene, meta and paradiispropylbenzene. It is significant that they report the specific paraffin hydrocarbon PROPANE to be a product of the reaction. The formation of PROPANE reported by Heise and Töhl has led the authors to review the data of Rittman, Byron and Egloff[18] upon the "Thermal Reactions of Aromatic Hydrocarbons in the Vapor Phase." The analytical results are given in distillation cuts and specific gravity of cymene, xylene and toluene fractions which have been subjected to varying temperature and pressure conditions. A scrutiny of the specific gravity of the benzene cut to 100 deg. C. shows a set of values ranging from 0.855 to 0.883 at 15.5 deg. C.

It is well known that the specific gravity of hydrocarbons is an additive property, and hence any value less than the specific gravity of pure benzene at 15.5 deg. of 0.883 must be due to a hydrocarbon or group of hydrocarbons with a specific gravity of less than 0.883 to bring it down to 0.855 at 15.5 deg. C. The lowering cannot be due to toluene, which has a specific gravity of 0.871 at 15.5 deg. C., hence in the *thermolization and pressurizing of aromatic hydrocarbons some paraffins or naphthenes must have been formed.* To what extent paraffins or naphthenes are formed requires further experimentation. In the present investigation of the action of aluminium chloride upon aromatic hydrocarbons the formation of hexahydrotoluene has been noted and will receive attention shortly.

Heise and Töhl treated ethyl, propyl[19] and butyl benzene with hydrogen chloride and aluminium chloride.

The products of the reaction for ethylbenzene were benzene, diethylbenzene (m) (p) and triethylbenzene. Propylbenzene gave as reaction products benzene, (m) (p) diproplybenzene upon six hours' heating with hydrogen chloride and aluminium chloride.

Under similar treatment butylbenzene gave benzene, (m) (p) dibutylbenzene, (O), (m) and (p) xylene, pseudocumene and mesitylene. It is to be noted that they report orthoxylene which Ador and Riliet and also Anschütz failed to isolate in their reactions.

Homer[20] in 1907, upon heating naphthalene in the presence of aluminium chloride for a period of time ranging from thirty minutes to six hours, found a tar formation which upon analysis gave three distinctly new compounds with the empiric formulæ of $C_{14}H_{10}$, $C_{26}H_{22}$ and $C_{40}H_{28}$. She was unable to isolate the reaction products reported by Friedel and Crafts[21] of hydronaphthalene and hydronaphthyl. From a pale yellow oil, the fraction boiling between 215 deg. and 225 deg. C./10mm. gave a substance of the formula $C_{14}H_{16}$, which in all probability was either tetramethylnaphthalene or diethylnaphthalene. From a later absorption spectra[22] study of the compound it was found evidently to check up with 1, 4, 5, 8 tetramethylnaphthalene. From the fraction boiling above 300 deg. C./10mm. a red transparent resinous highly fluorescent solid was isolated having an empiric formula of $C_{26}H_{22}$. It was suggested that it might be a homolog of dinaphthanthracene $C_{22}H_{14}$, with a formula as shown by Russig.[23]

From absorption[24] values $C_{40}H_{28}$ has a constitution similar to ββ dinaphthyl, and therefore is probably tetranaphthyl. The empiric formula of $C_{26}H_{22}$ exhibits an absorption curve similar to picene, and hence is very likely an alkyl derivative of picene.

The course of the reaction as Homer indicates it follows: naphthalene → ββ dinaphthyl → tetramethyl or diethylnaphthalene → $C_{26}H_{22}$ homolog of dinaphthanthracene or alkyl derivative of picene $C_{40}H_{28}$ tetranaphythyl. The probable equation would be:

Heating for "hours" a mixture of benzene, aluminium chloride and hydrogen chloride in a sealed tube Gustavson[25] recovered an oil with boiling point range to 360 deg. C. and a resinous mass. He isolated a compound with a boiling point of from 230 deg. to 232 deg. C. identical in properties with 3-phenyl-1-methyl cyclopentane, as given by Borsche and Menz.[26] Another compound was isolated with properties the same as those given by Kursanoff,[27] which analyzed diphenylcyclohexane. The toluene observed by Friedel and Crafts, according to Gustavson, was formed most likely by the passing of a methyl group upon methylcyclopentane by transposition to cyclohexane and then dehydrogenation of the methylcyclohexane. The compounds isolated by Gustavson from the reaction upon benzene were 3-phenyl-1-methylcyclopentane and diphenylcyclohexane.

Scholl, Seer and Weitzenbock[28] in 1910 isolated the compound perylen from the action of aluminium chloride on naphthalene by refluxing at 180 deg. C. for one

[17]Annalen 270, 155; Berichte 24, 768.

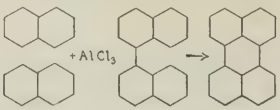
[28]Berichte 43, 2202, 1910.

hour. The course of the reaction as assumed by them, naphthalene to dinaphthyl to perylen as follows:



Homer[29] refluxing benzene ten to fourteen days with aluminium chloride at 100 deg. C. isolated naphthalene as one of the products which had been overlooked by Friedel and Crafts,[30] if it formed at all, under the conditions of their experiment. She isolated similarly to Friedel and Crafts—toluene, xylene, ethylbenzene, diphenyl and phenol.

An assumed explanation of the formation of naphthalene from benzene is given:

Contrary to the findings of Friedel and Crafts, phenol was isolated only in the lower cuts. The following formula weights were determined for the distillation products, and further work is going on to determine their constitution.

Distillation Temperature 10 mm. pressure	Molecular Weight
212 deg. C.	170
240	210
260	240
300	270

Summarizing the products reported by the various investigators upon the action of aluminium chloride and aromatic hydrocarbons, the following schematic outline is given which covers the actual compounds isolated under definite conditions of temperature and concentration. It must be recognized that the concentration of aluminium chloride, the time factor and temperature influence greatly the products resulting, and that no one reaction yielded all the products indicated, but that groups were isolated under definite conditions.

- Benzene
  - Toluene
  - Ethylbenzene
  - Diphenyl
  - Diphenyl-cylcohexane
  - 3-phenyl-1-methylcyclopentane
  - Naphthalene
  - Phenols
- Toluene
  - Benzene
  - Xylene (m) (p) *no* (o)
  - Ethylbenzene
  - Ditolyl (?)
  - Dimethylanthracene
  - Phenols
- Xylene (m)
  - Benzene
  - Toluene
  - Mesitylene
  - Pseudocumene
  - Durene
  - Tetramethylanthracene (?)
  - Phenols
- Mesitylene
  - Benzene
  - Toluene
  - Xylene
  - Pseudocumene
  - Durene
  - Isodurene
- Pseudocumene
  - Benzene
  - Toluene
  - Xylene (o) (m) *no* (p)
  - Mesitylene
  - Durene
  - Isodurene
  - Pentamethylbenzene
- Pentamethylbenzene
  - Durene
  - Isodurene
  - Hexamethylbenzene
- Hexamethylbenzene
  - Benzene
  - Toluene
  - Xylene
  - Mesitylene
  - Pseudocumene
  - Durene
  - Isodurene
  - Pentamethylbenzene
- Ethylbenzene
  - Benzene
  - Diethylbenzene (p) (m) *no* (o)
  - Triethylbenzene
- Propylbenzene
  - Benzene
  - Dipropylbenzene
- Isopropylbenzene
  - Propane
  - Benzene
  - Diisopropylbenzene
- Butylbenzene
  - Benzene
  - Dibutylbenzene (m) (p)
  - Xylene (o) (m) (p)
  - Mesitylene
  - Pseudocumene
- Cymene
  - Benzene
  - Toluene
- Naphthalene
  - Benzene
  - Hydronaphthalenes
  - Hydrogenated isodinaphthyl
  - Perylen
  - Alkyl derivatives of Picene ($C_{26}H_{14}$)
  - Tetranaphthyl ($C_{40}H_{26}$) (?)
  - 1,4,5,8 tetramethylnaphthalene
  - $C_{14}H_{10}$

Experimental

The experimental method consisted of distilling 500 c.c. of the aromatic hydrocarbon to which was added 10 per cent by weight of anhydrous aluminium chloride in a 1000-c.c. flask attached to a Glinsky column and 24-in. Liebeg condenser. The temperature of distillation was maintained over a period of twenty-four hours below the boiling point temperature of the aromatic treated. An evolution was noted of hydrogen chloride in each case of distillation. The distillate was neutralized with a 10 per cent sodium hydroxide solution, washed and dried over calcium chloride. The residue in the flask was filtered free of aluminium chloride, aluminium chloride compounds of the aromatic hydrocarbon used

[29] Proc. Camb. Phil. Soc. 16, 65, 1911.
[30] Loc. cit.

and carbon. The filtered oil was neutralized, washed and dried over calcium chloride, and added to the first distillate. The hydrocarbon liquid was then distilled in a Glinsky column and analyzed for its benzene and toluene content.[21]

The benzene was identified as the dinitrocompound and the toluene as the trinitrotoluene. The phenol present was identified by its boiling point and melting point. No attempt was made to isolate the cresols and higher phenolic compounds. The hexahydrotoluene was isolated by taking 100 c.c. of the fraction from benzene and toluene and by repeated extraction with fuming sulphuric and centrifuging after each treatment, and treating the residue liquid.

As many as twenty extractions with fuming sulphuric and five with fuming nitric acid were necessary to finally obtaining a liquid which resisted the action of both fuming sulphuric and nitric acid at room temperature. This unattacked liquid was then neutralized with sodium hydroxide, washed and dried over fused calcium chloride. The specific gravity, refractive index, boiling point and molecular weight by means of the vapor density method were taken of the residue liquid and clearly indicated hexahydrotoluene.

MATERIALS USED

Benzene.—The benzene used was water-white, thiofen-free and gave a specific gravity of 0.883 at 15.5 deg. C. and colorless upon sulphuric acid treatment. The distillation analysis:

Per Cent by Volume	Temperature Deg. C.
1st drop	79.5
99.5	80.5
Dry point	80.9

Toluene.—The toluene was water-white, clear color in the sulphuric acid layer. The specific gravity at 15.5 deg. C. 0.871. The distillation analysis:

Per Cent by Volume	Temperature Deg. C.
1st drop	109.0
99.0	110.5
Dry point	110.8

Xylenes.—The xylenes were water-white in color and gave a very faint lemon color in the sulphuric acid layer. This was cleared up to an almost imperceptible tint upon repeated acid treatment. The specific gravity of the mixture at 15.5 deg. C. was 0.870. The distillation analysis:

Per Cent by Volume	Temperature Deg. C.
1st drop	137.0
98.0	137 to 142
Dry point	143.2

Cumene.—The cumene used was water-white and slight lemon color on sulphuric acid treatment. The specific gravity of the sample at 15.5 deg. C. was 0.867. The distillation analysis:

Per Cent by Volume	Temperature Deg. C.
1st drop	151.0
94.0	155.0
99.3	160.0
Dry point	161.4

Cymene.—The specific gravity of the cymene used in this experiment at 15.5 deg. C. gave a value of 0.865. The distillation analysis:

Per Cent by Volume	Temperature Deg. C.
1st drop	173.0
98.0	175.2
Dry point	178.6

Experimental Data

A. BENZENE

The benzene after distillation over a period of twenty-four hours in the presence of 10 per cent by weight of aluminium chloride gave after neutralizing, washing and drying a percentage yield of 92 per cent of unchanged benzene, approximately 1 per cent of phenols and 6.8 per cent of tar. This is in accord with the findings of Friedel and Crafts, who found but little change in the benzene at its boiling point; but when they raised the temperature to 180 deg. and 200 deg. C. in a sealed tube considerable decomposition took place with toluene, ethylbenzene and diphenyl formation. Gustavson isolated 3-phenyl-1-methylcyclopentane and diphenylcyclohexane from the action of aluminium chloride upon benzene. Homer upon refluxing benzene from ten to fourteen days at 100 deg. C. found naphthalene resulting from the reaction.

The formation of naphthalene from benzene by the action of aluminium chloride is highly interesting. Zanetti and Egloff,[22] working with catalysts and varying temperatures in the gas phase upon benzene, were *unable* to isolate naphthalene, although every precaution was taken to find it in the reaction. They found the reaction took the following course:

$$\left.\begin{matrix}\text{Carbon}\\ \text{Hydrogen}\end{matrix}\right\} \leftarrow \text{Benzene} \rightharpoonup \text{Diphenyl} \rightarrow \left\{\begin{matrix}\text{Diphenyl benzenes}\\ \text{Condensation products}\\ \text{containing 3 or more benzene rings}\end{matrix}\right.$$

The action of aluminium chloride under the conditions of Friedel and Crafts, Gustavson and Homer's experiments upon benzene seem to be much more vigorous than temperature changes of Zanetti and Egloff's work. The benzene ring is disrupted entirely in forming naphthalene in the presence of aluminium chloride. The substances isolated from the action of aluminium chloride on benzene is tabulated as follows:

Benzene →
- Toluene
- Ethylbenzene
- Diphenyl
- Diphenylcyclohexane
- 3-phenyl-1-methylcyclopentane
- Naphthalene
- Phenols

B. TOLUENE

There resulted from the action of aluminium chloride upon toluene a yield of 15.0 per cent benzene and 3.5 per cent xylenes. Sixty per cent of the original toluene was recovered, and there were formed 1 per cent of phenols and 0.8 per cent of hexahydrotoluene.

The hexahydrotoluene was isolated by repeated treatment with fuming sulphuric and nitric acid upon the benzene fraction. After each treatment the mixture was centrifuged and the residue sulphonated. Toward the end of the sulphonation fuming nitric acid was used. The unsulphonated and unnitrated residue was then neutralized, washed and dried over fused calcium chloride.

The toluene used in the experiment was subjected to

[21] Rittman, Twomey and Egloff, Met. and Chem. Eng., 13, 682, 1915.

[22] Jour. Ind. Eng. Chem. 9, 350, 1917.

similar conditions in order to isolate any hexahydrotoluene which may have been present. The toluene source was a coal-tar oil and resulted from the thermal decomposition of coal, and it was thought that perhaps the hexahydrotoluene isolated from the reaction of aluminium chloride upon the toluene might have been present in the starting material. But not a trace of an unsulphonated or unnitratable residue was obtained. It is quite certain that the toluene used contained no hexahydrotoluene. The refractive index, specific gravity, boiling point and molecular weight of the residue, unsulphonated and unnitrated were taken.

The refractive index was taken by means of a Pulfrich refractometer; the specific gravity by means of a 1c.c. pycnometer; the boiling point by means of the Smith and Menzies[33] method for minute quantities of material and the molecular weight by the Victor Meyer vapor density method. The following table tabulates the data:

	Values for the Physical Constants Found Hexahydrotoluene	Values for the Physical Constants According to Beilstein
Refractive index	1.42775	1.41705 1.42430
Specific gravity	0.7648/15.5 deg. C.	0.778/0 deg. C. 0.7662/18.5 deg. C. 0.7641/20.0 deg. C.
Boiling point	97.2 deg. C.	98.0 deg. to 100 deg. C. 97.2 deg. to 98 deg. C.
Molecular weight Vapor density method	103	98

Gustavson argued that Friedel and Crafts' toluene from benzene formed via a methyl radical migrating from methylcyclopentane to hexahydrobenzene forming hexahydrotoluene and then by dehydrogenation to toluene. The evidence from the present paper indicates clearly the formation of hexahydrotoluene, a step which was pure speculation on the part of Gustavson. His explanation of toluene formation from benzene seems to have experimental verification, due to the actual isolation of hexahydrotoluene in the benzene fraction from the action of aluminium chloride upon toluene.

To the list of compounds isolated from the reaction products of aluminium chloride upon toluene, hexahydrotoluene must now be added:

Toluene:
- Benzene
- Hexahydrotoluene
- Xylene (m) (p) *no* (o)
- Ethylbenzene
- Ditolyl?
- Dimethylanthracene
- Phenols

C. XYLENE

Xylene is an excellent source of benzene and toluene by the action of aluminium chloride. The xylene upon treatment gave 19.0 per cent of toluene and 5.6 per cent of benzene, with a recovery of 30.0 per cent of starting material. Phenols and cresols were formed in appreciable amounts during the reaction. Hexahydrotoluene was isolated from the toluene fraction and gave the following constants, refractive index 1.41637, specific gravity of 0.7640 and a boiling point of 98.0 deg. C. and M. W. of 103. The starting material was subjected to the same treatment in regard to isolating the hexahydrotoluene but no trace was found in the original xylene.

The following list covers the compounds isolated from the action of aluminium chloride upon xylene:

(m) Xylene:
- Benzene
- Toluene
- Hexahydrotoluene
- Mesitylene
- Pseudocumene
- Durene
- Tetramethylanthracene?
- Phenols

D. CUMENE

Under the conditions of the experiment cumene formed 1.5 per cent of benzene; 2.7 of toluene and 26.5 per cent of xylene with 63.6 per cent of recovery for the starting material.

It would appear that there is a gradual splitting off of alkyl radicals, to the next lower homolog of benzene. Cumene does not appear to form benzene and toluene in yields sufficient to make it an important source for these two substances.

E. CYMENE

Cymene upon aluminium chloride treatment gave an excellent yield of toluene. The per cent of toluene upon the basis of cymene used was 14.3, with 0.8 per cent benzene and 7 per cent xylene formation.

The percentage of recovered material was 28.5 with 48.4 going to a jelly-like mass. Work upon this jelly-like mass is proceeding and will be reported upon in a future communication.

Tabulation of the Data

The data are expressed in percents of aromatic hydrocarbons upon the basis of aromatic hydrocarbon used in the reaction.

Hydrocarbon Used in the Reaction	Benzene	Toluene	Xylene	Cumene	Cymene
Per cent recovered of					
Benzene	92.0	15.0	5.6	1.5	0.8
Toluene	...	60.0	19.0	2.7	14.3
Xylene	...	3.5	30.0	26.5	7.0
Cumene	...	...	...	63.6	...
Cymene	...	...	...	...	28.5
Residue	6.8	20.0	43.0	4.4	48.4

Summary

1. A review of the literature dealing with the aluminium chloride reaction on aromatic hydrocarbons has been given together with conclusions as to the tendencies of the individual compounds under treatment.

2. A chart has been given of the specific compounds isolated from individual aromatics upon aluminium chloride treatment.

3. A naphthene overlooked by previous experimenters has been isolated from the reaction of aluminium chloride upon toluene and xylene and identified as hexahydrotoluene.

4. Quantitative recoveries, lacking in the literature for the hydrocarbons, benzene and toluene from the aluminium chloride reaction upon aromatics were determined as follows:

Benzene—slight change.

Toluene—15 per cent benzene, 3.5 per cent xylenes . . . .

Xylenes—5.6 per cent benzene, 19 per cent toluene . . . .

Cumene—1.5 per cent benzene, 2.7 per cent toluene, 26.5 per cent xylenes . . . .

Cymene—0.8 per cent benzene, 14.3 per cent toluene, 7 per cent xylenes . . . .

The Influence of High Temperature Upon the Elastic and Tensile Properties of Wrought Iron

By Frank A. Epps and E. Olney Jones

Owing to the comparatively recent use of iron and steel in a stressed condition at temperatures considerably above the usual range, it was thought by the authors that an investigation in this field might prove of commercial and engineering value. An examination of the engineering texts and literature showed that little had been done along this line, and the values that had been obtained were only for ultimate tensile strength, percentage elongation and percentage reduction of area. At the outset, therefore, it was decided to obtain reliable data on the variation of the elastic limit, and to check, if possible, the results obtained, by our predecessors, on the other properties.

The commercial application of the test is well worth considering. It is now generally admitted that all design work should be based on the elastic property of the metal, rather than on its ultimate strength. For metals at ordinary temperature, the use of a proper factor of safety brings the stress for which the piece is designed well within the elastic limit. As the results following will show, at higher temperatures this design factor of safety will have to be modified greatly, or the work will have to be designed wholly on an elastic limit basis. Up to the present, it is believed that this has been taken care of by greatly increasing the factor of safety when temperature conditions are to be considerably above normal. If the factor of safety has not been increased on the basis of experimental data, it is possible that there are instances now in existence where the metal is under a stress exceeding its elastic powers.

A few specific applications of the subject are given herewith:

Temperatures of superheated steam vary from 450 to 550 deg. Fahr. The strength of tubes, valve stems, etc., as affected by these temperatures, is indeed worthy of serious consideration.

Average boiler temperatures range from 300 to 450 deg. Fahr., and even within this range it is possible that the elastic properties of the metal are changed.

Metal rigging above large crucibles or ladles carrying molten iron is exposed to a heat far more intense than would be supposed. The failure of any part of such a system might result in a great loss to property and life.

Gas engine and gas turbine design is largely complicated by the temperature to which the metals may be safely subjected.

Blacksmiths have learned from the school of experience that iron should not be worked below a red heat. While it is not the purpose of this investigation to reach the temperature of a workable red heat (1500 deg. Fahr.), it will be shown that at least it is very inadvisable to work iron below temperatures of 1000 deg. Fahr.

In outline, the four main features to be considered are:

1. The metal to be tested.
2. The method of heating the specimens.
3. The method of measuring temperature.
4. The method of measuring elongation, particularly with the elastic limit.

It was decided to test a grade of wrought iron made directly from pig. All of the specimens were secured from the same lot, and further uniformity was assured from the fact that the grade was a special one and the iron unusually pure. The specimens were made 1 in. x ¼ in. flats milled down for a length of 5 in. to ½ in. x ¼ in. Flats were chosen because of the ease with which the specimens could be prepared, and because time was an important factor. The overall length of the specimen was determined from the size of the furnace and the necessary additional room required between the heads of the testing machine for the attachment of the extensometer.

An electric furnace was used for heating the specimen. Gas and gasoline heaters were considered, but it was thought that the gases of combustion might have an effect of changing the chemical properties of the iron, particularly in its heated state. The electric furnace was therefore chosen, not only because it eliminated this possibility, but because its construction, operation and control were simple.

In deciding upon the method of measuring temperature, the main considerations were durability, accuracy, simplicity and cost. A copper wire resistance pyrometer was first considered, but the suggestion was abandoned, because of the excessive oxidization of copper when exposed to heat. Platinum resistance was next proposed, but it was discarded in favor of base metal thermocouples which had all of the desired qualifications.

Provision for a satisfactory extensometer was the greatest difficulty encountered in the entire investigation. Strength, rigidity, lightness and accuracy in minute measurement were all essential features. It was necessary to read outside of the furnace, an elongation in five inches of not more than .005 in. A cathetometer was suggested, but the only one available had a least count of .001 in., which was clearly too large for accurate work. A cast-iron rigging was made so that a Berry Strain Gauge might be attached outside of the furnace. This failed to work on account of excessive friction in a sliding arm, and to generally unbalanced forces throughout the mechanism. Finally an instrument was devised that worked well and filled all the requirements. It will be explained later.

The furnace consisted of an inner cylinder of sheet iron 2 in. in diameter and 11 in. long. Around this cylinder is wrapped a layer of asbestos .1 in. thick, on which is wound 18 ft. of nickel-chrome ribbon, the total resistance being about eleven ohms. A sleeve of a special heat-resisting compound surrounds the inner cylinder. A half-inch wrapping of corrugated asbestos sheeting; ends of asbestos board, held together by four rods, and the necessary binding posts, etc., completed the furnace.

The thermocouples were made of iron and constantan wire, twisted together and welded on the ends. The wires were insulated with asbestos. Six of these were made. A Leeds and Northrup Potentiometer, used in connection with a standard cell, storage battery and auxiliary resistances, was used to measure the e.m.f. generated by the thermocouples. The cold end was kept at room temperature and the necessary correction was made. The potentiometer was used in preference to a millivoltmeter on account of the superior accuracy of the former for this class of work.

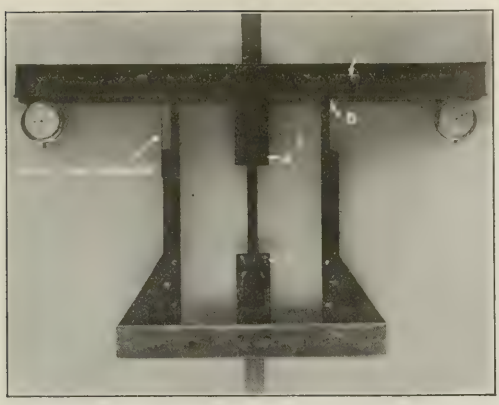

FIG. 1—EXTENSOMETER

The extensometer is shown in Fig. 1. The specimen is gripped by knife edges at *A-A* and the entire extensometer is supported at these two points. The uprights are free to move through the upper beam. A lever, supported by trunnion bearings at *C*, rests with one end on shelf *B* and the other on the movable shaft of a B. L. Ames Dial Gauge. A rubber band keeps this lever bearing continually on shelf *B*. The lever has a five-to-one ratio, the dial has one hundred divisions marked on it, one division being equivalent to the movement of the dial shaft or stem through .001 in. Consequently the least count of the instrument is 1/5 + 1/1000 = .0002 in. Readings of both dials were taken simultaneously and the average of these two readings was taken as the elongation. The grip pieces were made of cast iron; the remainder of the structure was made of No. 26 gage sheet iron, bent into channel forms, to insure rigidity, and riveted together.

CALIBRATION OF THE APPARATUS

Considerable time was spent trying to calibrate the furnace for temperature current relations, and for temperature variation in the inner shell. After such curves had been obtained, the furnace burned out, and it was necessary to rewind it. An attempt was made to secure similar curves for the second oven. The relation of current to temperature is only approximate. There was considerable of what might be called temperature lag; that is, if the oven was brought up to a certain temperature and held at that point, it would require a greater current than if the oven had been previously heated and the current so decreased as to allow the temperature to fall to the same point. Again the temperature lag in certain sections of the oven was different; that is, if the temperature was raised to a certain value, the temperature range in the oven would be quite different than if the temperature were allowed to decrease to the same value. The maximum variation of temperature was never greater than about ten per cent.

Owing to the fact that the temperature had different values in different parts of the furnace, readings of temperature were taken at three points, viz., top, middle and bottom. These were averaged by assuming the

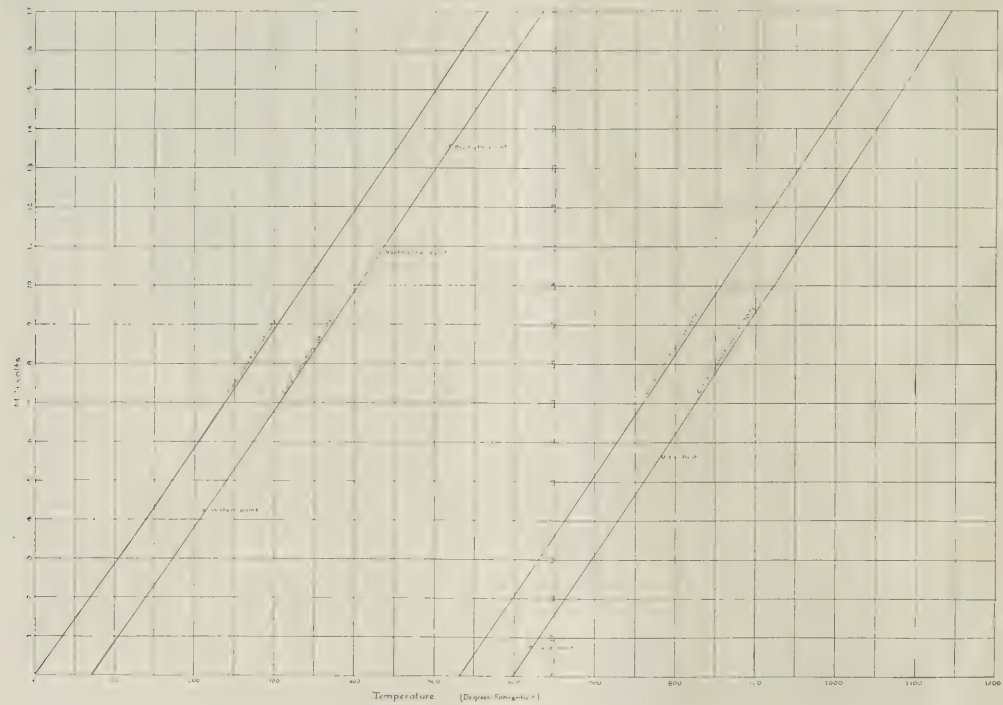

FIG. 2—CALIBRATION CURVE OF IRON-CONSTANTAN THERMOCOUPLE

change to occur along a second degree curve. This average temperature was taken as the temperature at which the elastic limit, modulus of elasticity, and percentage elongation occurred. Since the point in the oven at which the break occurred was readily ascertained, and since the temperature could be obtained at that point by means of a second-degree curve connecting the temperatures of the top, middle and bottom, that particular temperature was considered as the one at which the ultimate strength and percentage reduction of area were valid.

A calibration curve of an iron-constantan thermocouple shown in Fig. 2 was obtained from the Leeds & Northrup Company of Philadelphia. One of the "home-made" thermocouples was compared with this curve at the boiling points of water and naphthaline, and at the melting points of lead, bismuth and zinc. This couple compared very closely with the one for which the curve was drawn, and so it was assumed that for the case at hand the Leeds & Northrup curve was sufficiently accurate.

The other thermocouples, five in number, were tied with the calibrated one so that the junctions of all were as nearly as possible at the same point. They were then inserted in the furnace which was brought up to a fairly high temperature, and the e.m.f.'s generated by each were read almost simultaneously. Each registered the same e.m.f. in recording the same temperature, and so, in connection with the fact that all couples were made from the same pieces of wire, it was considered that this was ample proof that all were alike and answered to the one calibration.

The curve in Fig. 2 shows the Leeds & Northrup curve with the cold junction at zero degree Fahrenheit. A curve is also drawn for the cold end at 70 deg. Fahr. This was obtained by deducting the millivolts corresponding to 70 deg. Fahr., from the millivolts on the zero curve. The various actual points obtained by the calibration are corrected for the difference between room temperature and 70 deg. Fahr., and plotted over the 70 deg. curve. A maximum discrepancy of about 7 deg. Fahr. is observed at the boiling point of naphthaline. The naphthaline used was commercial "camphor," hence impurities present probably altered the boiling point slightly.

The extensometer was checked for accuracy by moving one end of the multiplying lever through a known distance by means of a micrometer screw, and reading the amount of motion on the dial. The error was less than one per cent. Both levers were checked in this manner.

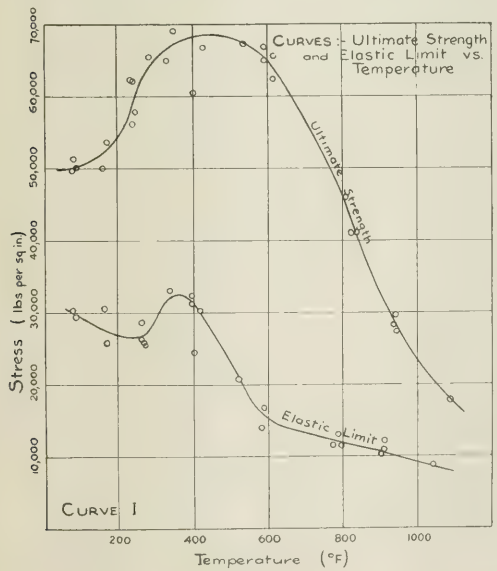
The testing machine was made by Tinius Olsen & Co. It was checked for accuracy by loading the table with known weights and measuring the same on the weighing beam, which had previously been balanced to zero. The error was so slight as to be negligible.

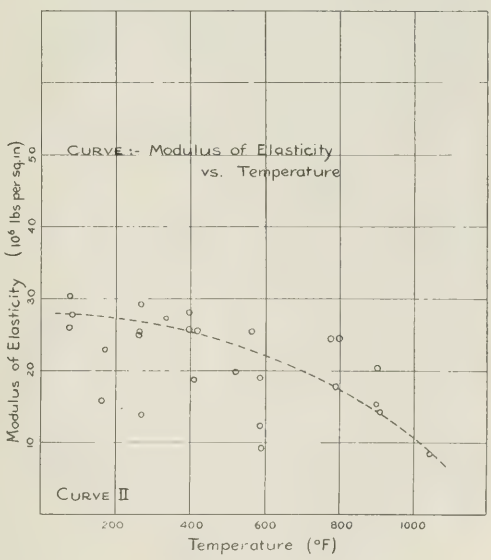
PREPARATION FOR AND CONDUCT OF TEST

Before actually conducting a test there were many preliminaries that had to be repeated for each. The first step was to determine accurately the dimensions of the specimen. The knife-edge extensometer grips were then placed on the specimen 5 in. apart, and made tight by means of bolts. By using knife edges instead of set screws and punch holes, the surface of the specimen was not damaged. In such a small specimen it is probable that a deep punch mark would so reduce the area of cross section as to weaken the specimen considerably at that point and cause the rupture to occur at the grips.

In attaching the thermocouples great care was taken to see that the welded tips were in contact with the specimen, so as to register more nearly the specimen temperature than the oven temperature. Three thermocouples were used in each test, one just below the top knife edge, one in the middle and one just above the bottom knife edge. From the readings of the three, the temperatures throughout the furnace could be closely approximated. These thermocouples were tied securely to the specimen by means of asbestos string.

The specimen and thermocouples were placed prop-





erly inside the furnace, the open ends of which were carefully packed with asbestos to prevent heat leakage. The extensometer was fastened to the projecting lugs of the knife edge grips, and the whole assemblage was finally put in the testing machine. Great care was taken at this point to get the specimen exactly in the middle of the top and bottom grips, so that the pull would be directly along the axis of the specimen.

The balance beam was adjusted to a correct zero reading and the specimen was stressed two hundred pounds for an initial reading.

Each test lasted, roughly, from twenty to thirty minutes. The machine was run at the lowest speed possible, about 1-in. movement of the drawhead per hour. The weighing beam was kept in constant balance, and for every one hundred and twenty-five increment in tension, the dials were read simultaneously. After passing the yield point, the dials would soon reach their limits, and a scale and vernier attached were used for measuring the further elongation to the point of rupture.

SUMMARY AND DISCUSSION OF RESULTS

A complete summary of all tests is given in the accompanying curves.

From these results it appears that the ultimate tensile strength of wrought-iron bars increases as the temperature increases from 70 deg. Fahr., until a maximum is reached between 350 deg. and 550 deg. Fahr.

From the temperature of maximum strength, the tenacity diminishes rapidly until the highest temperatures covered by these tests are reached.

The greatest gain over the strength of the metal at 70 deg. Fahr. was 37.6 per cent. This occurred at 430 deg. Fahr., as judged from curve I, page 69. The loss at 1000 deg. Fahr., over the strength of the metal at 70 deg. Fahr., was 53.5 per cent. A continuation of the curve at 1200 deg. Fahr. indicates a loss in strength of 75 per cent.

The elastic limit appears to decrease from 70 deg. Fahr. to about 270 deg. Fahr., showing a maximum decrease of about 13 per cent. From that temperature the elastic limit appears to suddenly increase to about 350 deg. Fahr., where it reaches its maximum value of about 10 per cent above the stress at 70 deg. Fahr. From here on it gradually drops and at 1000 deg. Fahr. shows a loss of 70 per cent over the elastic limit at 70 deg. Fahr.

Owing to a period of rapid yielding without increase of stress, the yield point is well defined at moderate temperatures. This yield point, however, vanishes at about 500 deg. Fahr., and the stress-deformation curve assumes a gradual slope from the start to finish.

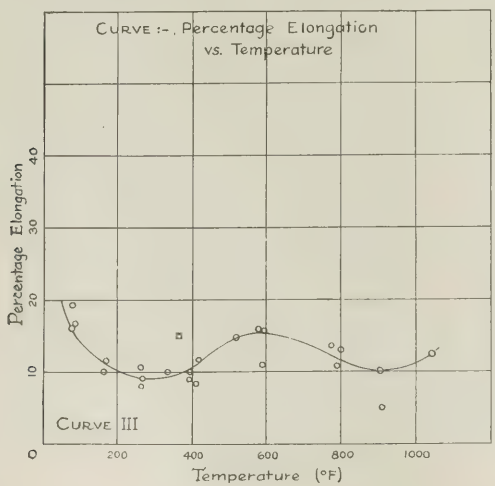
With reference to elongation under stress, this peculiarity is noticed: That greater rigidity exists under certain stresses at intermediate temperatures than at either higher or lower temperatures. Thus it will be noticed in Curve III that at 300 deg. Fahr. and 900 deg. Fahr. the metal shows only about half the elongation that it shows at 70 deg. Fahr. It is surmised that beyond 1000 deg. Fahr. the curve gradually rises and the metal exhibits powers of greater ductility as it approaches a workable heat.

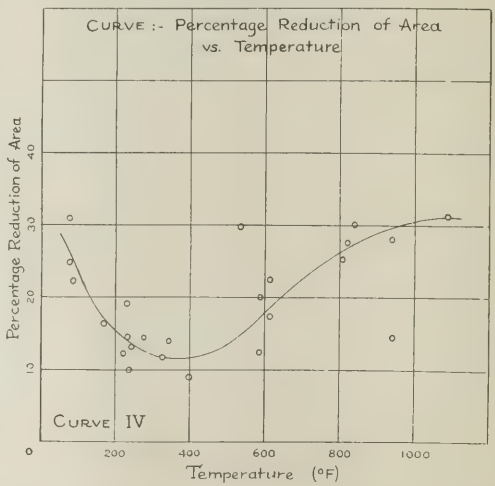
Other remarkable features in the elongations are found in bars tested at temperatures varying from 200 deg. to 400 deg. Fahr., in which there are displayed alternate periods of rigidity and relaxation under increasing stresses, resembling and yielding described as occurring with bars immediately after passing the elastic limit.

It will be readily observed how irregular Curve II is beyond the yield point. Some of the tests taken at this temperature showed even greater irregularity. The repetition of these intervals of rigidity and relaxation is suggestive of some remarkable change taking place within the metal in this zone of temperature, conspicuous in a series of tests possessing many remarkable features.

The contraction of area at the place of rupture varies with the temperature of the bar. It appears that the contraction of area of wrought-iron bars is a great deal less between 200 deg. and 600 deg. Fahr. than at 70 deg. Fahr., and within this range of temperature there is a tendency to fracture obliquely across the bar.

The results obtained for the modulus of elasticity have very little value, except that they indicate a gradual decrease. The length over which the stretch was measured (five inches) was too small to obtain an accurate





value of elongation within the elastic limit. The points obtained by the extensometer up to an elongation of .0008 inches were seldom of value, since it took nearly that long to get the test "under way." In drawing the average straight line through a series of points up to the elastic limit, the least difference in slope would make an appreciable difference in the elongation as measured by the abscissae. In some cases the least count in this elongation amounted to 5 per cent of the total, and in computing the modulus a variation of 5 per cent would mean a variation of perhaps a few millions. Consequently no curve was traced through the points, but instead a dotted curve was drawn showing the variation that might be expected according to the results obtained by other investigators (Curve II).

In all cases the temperatures recorded were those at the surface of the specimen. The accuracy of this method might be questioned, e.g., whether or not the recorded temperature was the actual temperature of the iron. This was investigated by drilling a hole in a specimen, inserting a thermocouple so that the welded tip was in the central part, and then carefully plugging up the hole so that no heat could get in by air conduction. It was demonstrated by taking the inner temperatures and the outer surface temperatures simultaneously that a maximum difference of thirty degrees might be expected at the highest temperatures. At low temperatures the difference was almost negligible. Consequently the authors felt justified in using the surface temperatures throughout, since the maximum error would only be a few per cent and the curves would not be changed appreciably.

It is shown conclusively that should similar iron be used in work where the design factor of safety was five, and where the temperatures were 900 deg. Fahr. or above, the part under consideration would be stressed beyond its elastic limit if the allowable stress was applied. Furthermore, at that temperature the factor of safety on the ultimate strength would be reduced to three. Curve I shows the relation of ultimate strength to elastic limit throughout the complete temperature range.

For tubes, valves, pipe lines, etc., carrying superheated steam, Curve I shows that at 600 deg. Fahr. the elastic limit has fallen 50 per cent of its value at ordinary temperature, hence a design factor of safety in superheater construction should be so modified as to give an ample factor on the elastic limit at this temperature. Assuming that the factor of safety is five on the ultimate strength at 70 deg. Fahr., this would be equivalent to a factor of three on the elastic limit at the same temperature. Therefore, considering that the metal should never be stressed to more than one-third of its elastic power, at 600 deg. Fahr., the factor of safety would have to be ten on the ultimate strength of the metal at 70 deg. Fahr.

Boiler temperatures do not come so high that it would be necessary to change the factor of safety in their design.

With reference to the metal rigging above large crucibles and ladles as previously mentioned, it is not known just what temperatures are reached, but they are probably as high at 600 deg. or 800 deg. Fahr., in which case it is clear that some allowance must be made for the temperature service alone.

Reference to Curve III indicates that the metal is very brittle between 150 deg. Fahr. and about 1100 deg. Fahr. Where this state exists it is, of course, impractical to work the metal. In other words, it would be better to work the metal cold than at 200 deg. Fahr., at which temperature it might fracture without warning. Nine hundred degrees Fahrenheit is even a more critical point, for here the ultimate strength and the elastic limit have dropped to less than half their original values.

The conclusions attained are rather startling. The wide fluctuations in the physical properties are not generally realized, and it seems that the field for further research is a wide one. An exhaustive series of experiments along the general lines of this investigation, on different grades of iron, steel, brasses, etc., and the publication thereof, ought to benefit the world of commercial design to a great extent. A microscopical analysis of the structure of the metals after having been broken at different temperatures, would very likely show interesting results, judging from the superficial examination of the breaks in this experiment. Tests conducted while the iron was in its recalescent stage would prove likewise an exceedingly interesting field for investigation.

Reference No. 1 deals with several metals including mild steel. The authors apparently have very good results for the modulus of elasticity, and they obtained values for ultimate strength and reduction of area very similar to those obtained in this investigation. It is possible, perhaps, that with the grade of metal used a definite yield point was obtained at as high a temperature as 550 deg. C. However, for most wrought iron and mild steel, it is impossible to obtain a definite yield point as indicated by the drop of the beam, after 500 deg. Fahr. or 260 deg. C. has been reached. This statement is confirmed by the experiments at the Watertown Arsenal in 1888, and by the investigations of Prof. C. Bach in 1904.

Reference No. 2 is merely a digest and translation of No. 3 by Prof. C. Bach, who reports very similar behavior to that observed in this investigation.

Reference No. 4 is the most complete treatise on record, and while the investigations herein disagree on minor points, still in main the phenomena observed are identical. This reference is the only one that contains any information concerning the elastic limit of the metal. Several grades of iron and steel were investigated, and it is noteworthy that they all showed similar characteristics.

Rubber Soles

By Andrew H. King

For quite a number of years we have been familiar with the type of rubber soled shoe known in the trade as "tennis." These slippers are made in many grades and styles. The most general characteristic has been cheapness. In fact, many of them are so cheap as to be next to worthless. Do not misunderstand me—there are good makes of tennis shoes, but to get them one must pay money. Because of this general cheapness both in price and in quality the public has come to look on a rubber-soled shoe as not exactly high class. That this is a mistake is now being forced home by extensive educational advertising.

Within the past two years the price of leather has advanced something like 120 per cent, and in fact genuine oak tanned leather is to-day extremely hard to get at any figure. People must have shoes, and since leather is beyond their reach a substitute must be found. Many times in the past the substitute has proved far superior to the original article. This case has been no exception, for with comparatively little effort rubber manufacturers have been able to turn out soles in every way equal, and in many ways superior, to any leather sole ever made.

The next step is education. Shoe manufacturers have had to learn the difference between rubber and leather. These differences while not great are nevertheless important, and the ways of building shoes have had to be altered a little to suit the new conditions. Shoemakers have done this because they were convinced of the virtue of rubber soles. The general public has been a bit skeptical, mainly because of the subconscious memory of the old tennis shoe. The best argument, perhaps, is in the appearance of high-priced $8, $10, and $12 rubber soled shoes bearing the name of reputable manufacturers. Last year rubber soles were a fad. To-day they are a necessity.

There is quite a little psychology in it. For a thing to be appreciated by the people at large there must be a perfect whirlwind of enthusiasm, a craze, a sort of mono-mania. In time this subsides and the great outstanding utilitarian virtues of the thing are generally accepted. It is not long ago that bicycles were the fad. Then the bubble burst, people's attention was directed elsewhere. Sales fell off and prices with them. But the bicycle was not done for. It has a place in the world because it is of use. To-day we have the three-speed bicycle and the motor wheel attachment. It is here to stay.

Tango dancers long ago discovered the usefulness of the rubber sole. In fact, the modern dances almost without exception, would be impossible without them. Then the thing became a fad. We are still in this stage, and of course are paying fad prices. It might be possible that a good all-leather dress shoe cannot be retailed for less than $8 a pair, but certainly this is a high figure when the soles are of rubber. Necessity for the craze has now passed. People know that a first quality sole can be made of rubber, and the next thing is to bring it down within range of their buying power.

The chief advantages of the rubber sole over the leather one are:

(1) Greater wearing power; *i.e.*, longer life.

(2) Being by nature absolutely waterproof.

The rubber sole properly made will last anywhere from two to three times as long as the leather one. This consideration is by far the most important. Theoretically, for good shoes the uppers and the soles should wear out at about the same time. Ordinarily a shoe will stand at least two more sets of leather half soles and heels. Consequently with a good rubber sole this theoretical condition is more nearly approached.

Leather is a porous, fibrous substance and to be made waterproof requires the use of large quantities of various waxes and greases. Rubber is non-porous and watertight by nature. This fact constitutes the main objection to the rubber sole, for not only is it watertight, but airtight as well. It is claimed that leather allows the feet to breathe and in this way prevents burning. However, this is really only a minor point and can be remedied by using canvas uppers or by some form of a ventilator.

Another objection is that a rubber sole tends to slip on a wet pavement. With the first ones it was hardly possible to walk with them on rainy days. This trouble has now been almost entirely done away with by incorporating into the rubber cotton fiber or ground leather, or both. Consequently as the sole wears away a surface is produced which will absorb a little water and thus prevent slipping.

The first rubber soles were quite heavy. It did not seem possible to prepare a stock with the desired stiffness, strength, and quality without having it also of high specific gravity. This was not to be thought of, for the addition of even half a pound to the weight of one's shoes has an effect quite noticeable at the end of a day's work. The introduction of ground cotton waste and leather dust as compounding ingredients made it possible to bring the gravity down to 1.25-1.35.

The manufacture of soles is quite simple. It may be outlined as follows:

(1) *Preparation of the cotton fiber:* Various kinds of rags and trimmings, depending mostly on the color and quality of the sole, are put through a shredding, grinding, and fluffing process. In the end the fibers are reduced to not much more than 1/32 in. in length.

(2) *Preparation of leather dust:* Trimmings from the shoe factories and repair shops are ground very fine, and usually are air separated. It is customary also to make up a master rubber by milling in a considerable percentage of the dust and refining it a number of times to remove the lumps. This master rubber is weighed up and mixed as usual in the main batch.

(3) *Rubbers:* Depending on the quality of the sole more or less rubber and shoddy are used. These are of the common grades. The shoddies must, however, be of low gravity. The backbone of the sole business is reclaimed auto-friction. This is the rubber-coated duck used in the building of the carcass of auto tires. Whether this building is done by hand or by machine there is an enormous amount of trimmings to dispose of. These trimmings carry quite a lot of unvulcanized rubber, which is of better quality and higher purity; *i.e.*, with less compounding material, than that of any other place in the tire. The rubber is either reclaimed by a modified acid process or extracted with solvents. In the latter case both the rubber and the fabric is usable, whereas in the former the cotton is destroyed. However, the extraction process requires very careful supervision to be profitable, and it is a question as to which

method is the more economical. The reclaimed rubber is of high quality and low gravity, and makes a highly satisfactory sole. As would be expected, by far the largest portion of rubber soles and heels are made by the large tire companies.

(4) *Milling:* The actual preparation of the batch is not difficult and is carried out on ordinary rolls in the usual manner.

(5) *Calendering:* The stock is plied up very carefully to the desired thickness and sent in rolls to the cutting room.

(6) *Cutting:* The soles are stamped out by means of dies in a cutting machine. The dies are carefully adjusted so that there shall be but very little overflow during the cure.

(7) *Muring:* This is accomplished in molds in the usual way. The trademark, name of maker, and any special marks are put on in the mold. The cure is usually short but with a high steam pressure. 25 minutes to 60 lb. is not uncommon.

(8) *Trimming:* Usually done by girls, on regular trimming machines.

(9) *Varnishing:* Accomplished ordinarily by dipping. Either a spirit or water varnish may be used. It gives the sole a nicer appearance and prevents blooming.

Following drying, the soles are ready to be packed and shipped to the shoe makers.

A good sole will have a tensile strength slightly in excess of 1000 lb. per square inch, but will have a very low stretch. It must not be brittle nor break across when given a surface cut and then bent double.

For very rough, heavy shoes, such as are worn by teamsters, iron workers, and railroad section men a new sole is coming into favor. It consists of a number of plies of heavy duck built like a belt, and stamped out to size with a die. Rubber or balata is used to cement the plies together. Such soles have rather unsightly edges but from the standpoint of service they are very satisfactory.

To the keen observer it must be apparent that leather shoes are going, in fact have gone, beyond the means not only of the poorer classes but that of the better middle classes as well. War conditions and speculation are largely to blame. It is the American way to beat such a condition not entirely by legislation but by invention—invention of a substitute.

A number of rubber soled shoes with canvas uppers are now being placed on the market. Canvas uppers can be waterproofed if desired in a number of ways. For instance, they can be waxed, rubber coated, or built of three plies, the inside one of fabric which has been frictioned and skim coated on both sides. The present offerings are but feelers which will, no doubt, be followed up with a good, all-around canvas-rubber shoe. Such a shoe must be neat appearing, serviceable, and have a long life. There is certainly no reason why it cannot be made.

Steam Packing.—French chemists have found a specimen of klingerite (a German steam pipe joint packing) about a sixth of an inch thick to consist of 15 thicknesses of thin asbestos. Analysis showed 80.5 per cent of asbestos, 2.2 of cellulose (flax), and 17 of rubber and balata, with a small proportion of sulphur.

Modern Concentration of Colorado Tungsten Ores—II

By S. Fischer, Jr., Ph.D.

(*Concluded from Vol. XVI, p. 565*)

The Black Prince Tungsten Mill

This mill is situated at Ferberite in Boulder Canyon about seven miles from Boulder, Col. The plant handles its own ores from the group of the Black Prince mines, many of which are operated by leasers. The ore runs from 1.5 to 60 per cent tungstic acid, the high-grade material being shipped directly without passing through the mill. The capacity of the mill is 25 tons per day. It is at present contemplated to increase the capacity of the mill to 75 tons per day. The concentrator is operated by electricity, the power coming from the Colorado Power Co. The mill uses three Westinghouse motors of 15, 7.5 and 10 hp.

The general flow sheet of this concentrator is similar to those shown with the exception, that a Denver quartz mill is used for fine grinding instead of a ball mill. This mill is of the Chilean type and it is claimed gives very satisfactory results in this instance, producing a very uniform product of the desired mesh. Fig. 1 shows the flow sheet of this mill.

The ore from the mine run passes to an 8 in. x 12 in. Denver steel crusher, the oversize passing to a set of 12 in. x 20 in. McFarlane-Eggers rolls from where it is elevated to the fine ore bin together with the undersize from the crusher. The material from this bin is fed to a No. 2 Denver ore feeder and goes to a 12 in. x 12 in. Richards jig. The jig concentrates are collected, dried and sacked for shipment. The tailings from the jig go to a No. 1 Denver quartz mill where a 30 mesh product is obtained. This product then passes to a Loves classifier and dewatering device. The overflow and slimes from this last combination are fed to a Callow cone, from which the overflow is conducted to the canvass plant and the thickened slime to a Monell slimer.

From the first dewaterer the coarse pulp is conveyed to one side of an Isbell concentrator, the high-grade concentrates are collected, the middlings pumped back

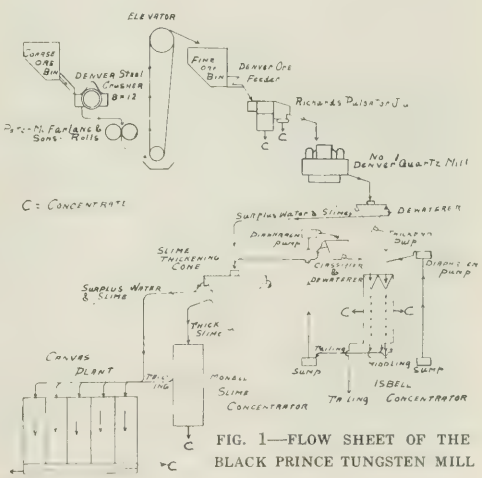

FIG. 1—FLOW SHEET OF THE BLACK PRINCE TUNGSTEN MILL

to the head of the table and the tailings are pumped to a classifier. The overflow from this classifier goes to the Callow tank and the sands to the opposite side of the Isbell concentrator.

The low-grade concentrates from this side of the Isbell are collected. The middlings are returned and the tailings go to waste.

Of particular interest are the following items, which the writer in this instance is at liberty to mention: from the assays shown the mill is making a saving of 84.3 per cent. The heads run 1.3 per cent tungstic acid and the tailings 0.22 per cent.

Fig. 2 shows the mill as it looks at present. The mines and mill are owned by John T. Duncan, of Boulder, Col.

The Tungsten Mines Co

The Tungsten Mines Co.'s mill and mines lie about two miles north of Rollinsville. The mill was built in 1910 and is owned by a few individuals. The ore from the mine runs to a Denver crusher, the oversize passing to 12 in. by 20 in. McFarlane-Eggers rolls, thence to two No. 1 Denver Quartz mills and from here to a classifier. Wilfley tables and Monell slimers are used at the plant. It might be stated here that as a general rule Wilfley tables are preferred to Isbell concentrators throughout the district. No data as to the percentage extraction could be obtained, but the mill was operating successfully even at the time when tungsten was selling at $7 per unit.

The Intermountain Tungsten Mill

This company owns the Black Swan mill at Salina, Col. The concentrator handles partly its own ores and partly the custom ores from neighboring mines.

The flow sheet of this as well as the mill of the Tungsten Mines Co. is in general similar to the one of the Black Prince mill, only that in both of the last two mills Wilfley tables replace the Isbell concentrators. The Black Swan mill has one more distinctive feature in that it uses stamps. The ore is crushed by an 8 in. x 12 in. Denver crusher. From this crusher the material passes to ten stamps, is then classified, and the oversize reground in a No. 2 Denver quartz mill. From here the product goes to Wilfley tables and Akins and Evans slimers. Finally the fines pass to a stationery canvass plant.

The Luckie 2 Mill

The flow sheet of the Luckie 2 mill is given in Fig. 3. The plant handles 25 tons of ore per day which comes from the company's own mines. The mine ore comes to eight bins of 8 tons capacity each. From these bins it passes to an 8 in. x 12 in. crusher and then to 12 in. x 20 in. McFarlane rolls where it is crushed to 1-in. size. This material then is passed over a trommel screen with ¼-in. openings. The undersize is sampled by a Vezin sampler, the reject going to the bin containing as a maximum ¼-in. size. The oversize is sent through a second set of McFarlane rolls in closed circuit with the trommel screen until all is reduced to at least ¼-in. size, when it also passes into the bin mentioned.

The material from the ¼-in. bin, as well as any custom ore which is kept on the floor enters a vibrating screen. This screen has 12 mesh openings. The plus 12 mesh product passes directly to a Richards pulsating jig, which yields concentrates which are collected from the top of the screen, dried and sacked. The material passing through the screen goes to a Denver quartz mill and then to a hydraulic classifier. The

FIG. 2—BLACK PRINCE TUNGSTEN MILL

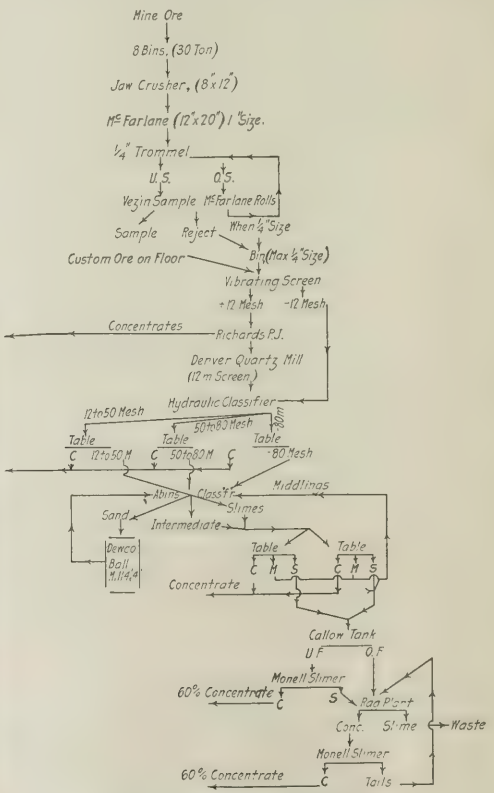

FIG. 3—FLOW SHEET OF LUCKIE 2 MILL

minus 12 mesh product from the vibrating screen passes directly to the classifier.

The hydraulic classifier yields three products: the first ranges from 12 to 50 mesh, the second from 50 to 80 mesh and the third is minus 80 mesh. All these products go to three Wilfley tables where only the concentrates are collected, the rest of the material passing to an Akins classifier. This latter gives sand, an intermediate product, and slimes. The sand circulates between a ball mill and the classifier until slimed, when it is distributed to two Wilfleys. The slimes and the intermediate product go to the same tables without any further treatment. The concenrates from these tables are collected for shipment. The middlings return to the classifier and the slimes go to a Callow tank. The over-flow from the Callow enters the "rag plant," while the underflow is passed over a Monell slimer, the slimes from this then going to the "rag plant."

The "rag plant" consists of two tiers of six tables each. The lower tables are 6 ft. x 36 ft. while the upper ones are 6 ft. x 26 ft., thus giving a total canvass area of 2232 sq. ft. The slimes from the "rag plant" go to waste, while the low-grade concentrates pass over a Monell slimer giving a 60 per cent concentrate and tails which are returned to the "rag plant." The mill endeavors to produce 60 per cent concentrates throughout the operation, which are sold to the Tungsten Products Co. of Boulder. The ore treated at this plant averages about 7 per cent tungstic acid. Fig. 4 gives a general view of the mill.

Some features at this mill are worthy of notice. The Denver quartz mills used are employed as intermediate grinders only, the Dewco ball mill doing the final fine grinding. It is claimed that with this arrangement the large bulk of material handled per day is crushed to the fine state in a shorter time than if the quartz mills were used alone. The rag plant circulating system is the other item worthy of notice. Finally it should be stated that the flow-sheet presented in this article is not the one embodying the mode of operation at the time of the author's visit, but is that of the final mill, including new features and machines.

The Mill of the Rare Metals Ore Co.

Both from an engineering and an efficiency standpoint this mill undoubtedly is one of the finest examples of the district. The mill treats custom ores and is able to handle 50 tons of 1.5 per cent material or 25 tons of 4 to 5 per cent ore. The practice at the mill is to state the number of units of tungstic acid handled per 24 hours rather than the tonnage of ore treated in the same length of time. In other words the plant handles 100 to 150 units of tungstic acid per day. The average mill ore runs 4 per cent tungstic acid.

FIG. 4—LUCKIE 2 MILL

Due to the fact that this mill is a typical example of efficient engineering its flow sheet was given at the beginning of this paper (see this journal, May 15, 1917, Fig. 1, p. 560). The flow sheet may be divided into two concrete parts, the sampler flow sheet and the mill flow sheet. On entering the mill, the ore is weighed and transferred to receiving bins. From these bins the product is passed through a 10 in. x 16 in. Blake crusher where the ore is reduced to 1.5-in. size. No. 1 elevator raises the crushed material to a set of rolls (14-in. x 27 in.) reducing the product to ½ in. This ½-in. material is sampled by a 36-in. Vezin sampler, which takes a 1/5th cut. The reject goes to the No. 2 elevator from where it is passed into the mill bin, containing as a maximum size ½-in. ore. The sample from the Vezin passes through a set of 12 in. x 20 in. rolls where a reduction to ⅛ in. size takes place. This material is again sampled by a 20-in. Vezin taking a 1/5th cut. The reject passes to the No. 2 elevator and from there to the mill bin. The second sample is coned and quartered to a 20 lb. sample, dried, ground and rifled to assay pulp.

From the mill bin the ore passes into the mill proper through a plunger feeder which feeds to the No. 3 elevator. From here the product goes to an impact screen with ⅛-in. openings. The oversize from the screen is passed through the No. 1 set of 14 in. x 27 in. rolls from where it goes back to the No. 3 elevator. The undersize from the impact screen is fed to the No. 2 impact screen having 1/16-in. openings. The oversize from this screen passes to a two-compartment Hartz jig, which gives concentrates, a hutch product and a third product which latter passes over a dewatering screen and from here goes to the No. 2 5.5 in. x 20 in. high-speed rolls which reduce the product to 1/16-in. size. This then enters elevator No. 3 to continue its passage through the mill.

The underflow from the No. 2 impact screen goes to a two-compartment hydraulic classifier the overflow of which is conducted to a 36-in. Akins classifier. The underflow of the one compartment of the classifier unites with the hutch product from the Hartz jig and goes to the No. 1 Wilfley table. The underflow from the other compartment of the classifier goes directly to a No. 2 Wilfley. The Hartz concentrates are collected, dried and sacked. The same holds true for the concentrates from the first two Wilfley tables. The middlings from No. 1 and No. 2 tables pass through a hydraulic pipe classifier, giving a spigot concentrate running between 55 and 60 per cent tungstic acid. The second product of this classifier goes back to elevator No. 3.

The Akins classifier receives material from the dewatering screen from elevator No. 4 and from the ball mill. It yields three products, the slimes of which go to the Callow tanks, the intermediate product which are classified and the sands which are slimed in the ball mill. The ball mill, which is of the Colorado Iron

Works type, is 4 ft. x 3 ft. and is in closed circuit with the Akins classifier and elevator No. 4.

The slimes after treatment in the Callow tanks yield two spigot products, each of which goes to a separate Deister slimer, the concentrates of which are collected, the middlings going to elevator No. 4, while the tailings go to the "rag plant." The overflow from the Callows unite and enter the "rag plant." The intermediate product from the Akins is classified in a hydraulic classifier, the spigot product of which goes to Wilfley table No. 3 while the overflow goes to Wilfley No. 4. The distribution of the table products is identical with those obtained on the Deister slimers. The overflow from the sand classifier goes to seven canvas tables each being 6 ft. x 24 ft. and set at a drop of $\frac{3}{4}$ in. per foot. The spigot product from the sand classifier goes to the tails ponds. The concentrates from the canvas tables are pumped back to elevator No. 4 by means of centrifugal pumps.

This mill produces concentrates of at least 60 per cent tungstic acid content. The extraction is remarkably high, but the writer is not at liberty to give the exact figures. To attain this high mark of efficiency various novel features are connected with the construction of this mill. As is seen from the flow sheet, the sampling of all the ores is accomplished with the greatest of care. The only mechanism which did not come up to the expected standards of efficiency is the distributing elevator No. 2, the moving shute of which is rather a detriment than an asset, due to the wear and the labor involved in its manipulation.

In the choice of the machinery for the mill proper the greatest care has been exercised. While the flow sheet may seem complicated, one is struck with the compactness and neatness of the plant on visiting the same. The whole scheme then seems simple and is readily understood. Attention should be drawn to the arrangement of the No. 1 and No. 2 rolls and of the use of high-speed rolls on the dewatered Hartz jig product. The handling of the middlings from the Wilfley tables No. 1 and No. 2 is novel and affords a considerable saving. This product passes through a hydraulic classifier, designed by the staff of the mill, which is locally known as the "hickey." The spigot product is of commercial grade and saves this material from again passing through the mill.

The treatment of the intermediate product from the Akins classifier is also worthy of notice, as most of the local plants handle only two products from this classifier, the slimes and the sands.

The water supply to the canvass tables at this plant are also distinctive. Instead of having the regular Wilfley type of feed, these tables taper toward the upper end, the water entering at the apex and being distributed at will by movable guides as shown in Fig. 5.

Provisions for cleaning up the mill floor have also been made, the floors being inclined toward elevator No. 4. From time to time the floors are washed with a hose, the material gathered in the elevator and sent through the mill. Even the workmen undergo a daily washing, provisions being made for shower baths. The "efficiency" of this latter process has however not been calculated.

It is really astonishing to see how much one may save by supervising the small losses. For instance, at this plant the ashes from the drying furnaces are saved every day and when a sufficient amount has been collected it is again passed through the mill. This amount figures approximately 6 lb. of tungstic acid saved per day.

As this plant represents the successful practice in the ore dressing of the Nederland tungsten district, the complete plans of this mill are given in Fig. 6.

The Tungsten Losses

As has been stated in the earlier part of this paper, as much of the values as possible should be eliminated from the ore before fine grinding. Before the installation of the "rag plant" at the mills the tailings went to waste. These tailings carried values which in the modern practice are to a large extent recovered. Some very careful tests were run on the various tailings according to the various meshes, for the tungstic acid content, just before entering the "rag plant." The results are taken from the tails of the Rare Metals Ore Co.'s mill and are given in the following table:

Mesh	WO_3 Content	Percentage Loss
20-40	0.63	2.0
40-60	0.57	6.9
60-80	0.375	7.0
80-100	0.365	2.0
100-200	0.275	10.1
-200	1.41	66.0
		100.0

These data indicate, that by far the largest percentage of the losses are found in the -200 mesh material. At present, with the use of the "rag plant," the tailings as they leave the mill and enter the settling ponds carry approximately 0.75 per cent tungstic acid as losses. Of these losses 66 per cent are contained in the -200 mesh material. It has been experimentally ascertained, that only 31 per cent of the 66 per cent losses could be recovered in these ponds. This demonstrates the great difficulty encountered in endeavoring to recover any large amount of values from the losses in the finest tailings leaving the mill. It is claimed that the installation of the "rag plant" in a mill saves

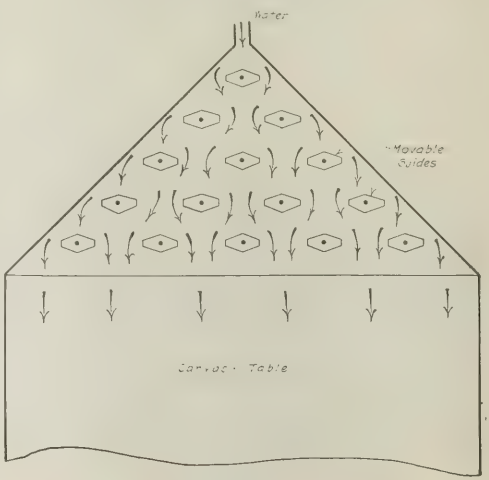

FIG. 5—WATER FEED TO CANVAS TABLE

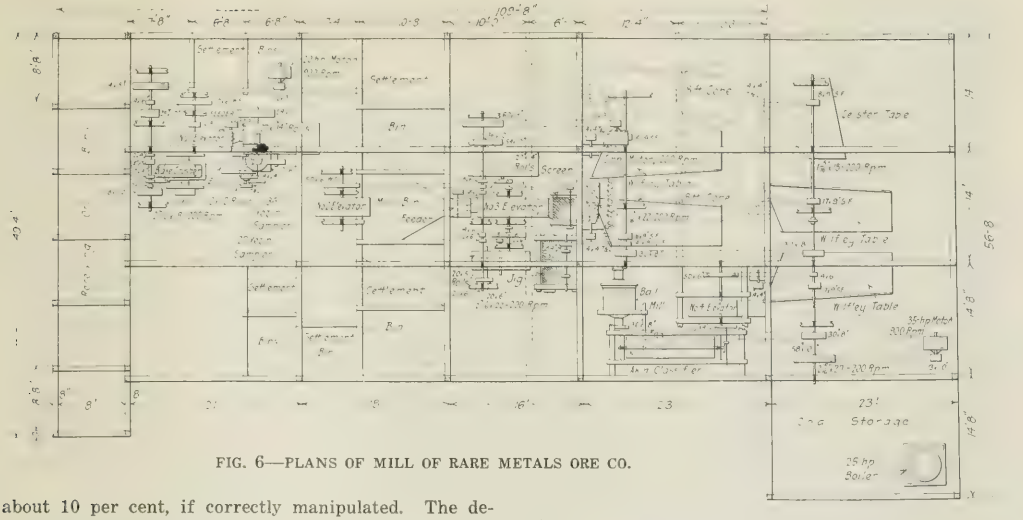

FIG. 6—PLANS OF MILL OF RARE METALS ORE CO.

about 10 per cent, if correctly manipulated. The dewatering of the pulp before sending it onto tables in connection with the installation of a "rag plant" at a concentrator will procure a saving of approximately 15 per cent.

Future Improvements in the Ore Dressing Methods of the District

As the ore dressing methods for ferberite ores have reached a high state of refinement, it is hardly possible that there will be any further striking features along the lines of improvements. The main trend will be to increase the percentage of extraction. Endeavors will be made to eliminate more of the values before fine crushing, to dewater the pulp before going over the tables and to cut down the square feet of the canvass in the "rag plant" to a minimum. These little phases will in all probability be kept secret by all the companies, so that new material will be rather difficult to obtain, until that time when such features as flotation and magnetic separation have been more thoroughly investigated.

Attempts to use both flotation and magnetic separation have been made at various mills in the district, but the results obtained seem to discourage either practice. It is, however, unfair to say that both these methods are of no value in the practice of the district. The work done along these lines seems, as far as the writer could discover, insufficient to justify giving a final verdict upon the subject. The ores of the district are rich enough to guarantee enough concentrates for the present. In time, however, the recovery of the values in the very low-grade materials will have to be taken into consideration and then either one or the other or in all probability both of the methods mentioned combined with a previous roast may prove of value.

It might be stated here that the practice in the dressing of tungsten ores as developed in Boulder County is of the highest standard and there is no reason why the same methods of concentration might not be used on any of the commercial tungsten ores, such as scheelite, wolframite and huebnerite. The specific gravity of scheelite varies from 5.9 to 6.1 and that of both wolframite and huebnerite is 7.2, being practically the same as that of ferberite. The latter mineral is a modification of wolframite with little or no manganese.

The Future of the Metallurgy of Tungsten

The main use of tungsten is in the manufacture of tungsten steels for various uses, such as for high-speed tools and as used in the manufacture of ammunition. Furthermore, tungsten has an industrially very important field in the manufacture of filaments for incandescent lamps, though the quantity of tungsten consumed for this purpose, as compared with the consumption for tungsten steel, is insignificant. While the demand for the metal, due to the present war is considerable, the feeling among the miners of tungsten ores is that after peace has been declared, the tungsten market will suffer, due to the lack of demand for the metal or tungsten alloys in the arts. The feeling is prevalent in the district, that more work should be done respecting the use of tungsten in the arts so as to insure the future of the industry. There can be no doubt, however, that tungsten steel will play a very important part in the reconstruction period after the war.

Some think that the greatest danger confronting the tungsten metallurgy would be the discovery of large molybdenum deposits. The one great drawback in the use of tungsten for steel is the large amounts required to produce the desired effects in the steel, and it is claimed that molybdenum on the other hand produces the same qualities in steel using one-third the amount of this metal as compared with tungsten.

Small deposits of molybdenum have been located not only in Colorado but also in other parts of the United States, but from a commercial point of view, their working has received little consideration, due to the small amount of material available. Then, too, the dressing methods for molybdenum ores have not been developed sufficiently to guarantee their economic working. The largest molybdenite deposits so far known are in the Province of Ontario, Canada. These deposits have been studied by the Canadian Bureau of Mines as to their nature and extent. Metallurgical methods best suited for their concentration have been investi-

gated. In tests run at the laboratories of said bureau, and extending over a period of approximately two years, it was found, that the most suitable procedure would be to coarse grind the ore, separate the flaky concentrates as far as possible during this stage, then fine grind the rest of the material and subject it to flotation by water. Extractions as high as 84 per cent were obtained and it is claimed that in practice the percentage extraction would, in all probability, be considerably higher. While the prices of molybdenum, molybdic acid and ferro-molybdenum are higher than the prices for the corresponding tungsten products, the smaller amounts of molybdenum required to produce the desired effects in steel would by far offset the lower prices of the tungsten products. This undoubtedly would mean that molybdenum would be preferred in the steel industry for the manufacture of tool steels and ammunition.

Conclusion

In conclusion the writer wishes to express his sincerest gratitude to the following gentlemen for their kind assistance and their valuable information: Mr. W. F. Bleecker of the Tungsten Products Co., Mr. C. A. De Witt of the Wolftongue Mining Co.; Mr. J. G. Clark of the Tungsten Production Co.; Mr. G. B. Tyler of the Rare Metals Ore Co.; Messrs. John Connors and T. McGrath of the Vasco Mining Co.; Mr. H. B. Holmes of the Luckie 2; Mr. J. S. Bartley of the Denver Quartz Mill & Crusher Co.; Messrs. H. B. Lowden and R. P. Akins of the Colorado Iron Works and Mr. J. H. Flood of the Hendrie & Bolthoff Mfg. & Supply Co.

British Standard Nomenclature of Bituminous Material

FIRST GROUP—TAR PRODUCTS (PRINCIPALLY COAL TAR AND PITCH)

1. *Tar.*—Tar is the matter (freed from water) condensed from the volatile products of the destructive distillation of hydrocarbon matter, whether this be contained in coal, wood, peat, oil, etc. A prefix such as coal, gas-works, blast-furnace, etc., must be added to the word "tar" to indicate the source of origin.

2. *Pitch.*—Pitch is the solid or semi-solid residue from the partial evaporation or distillation of tar.

SECOND GROUP—BITUMENS AND ASPHALTS

3. *Bitumen.*—Bitumen is a generic term for a group of hydrocarbon products soluble in carbon disulfide, which either occur in nature or are obtained by the evaporation of asphaltic oils. The term shall not include residues from paraffin oils or coal tar products.

4. *Native Bitumen.*—Native bitumen is bitumen found in nature, carrying in suspension a variable proportion of mineral matter. This term shall not be applied to the residuals from the distillation of asphaltic oils.

5. *Asphalt.*—Asphalt is a road material consisting of a mixture of bitumen and finely graded mineral matter, ranging to such a size as will pass through a sieve having square holes of ¼-in. side.

6. *Native or Rock Asphalt.*—Native or rock asphalt is a rock which has been impregnated by nature with bitume.

The committee recommends that prefixes denoting the source of origin should be attached.

The Possibilities of Developing an American Potash Industry[1]

By Richard K. Meade

About a month ago this paper was started by quoting Professor Ostwald's well known remarks concerning Germany's ability, through her control of the only known large deposit of potash salts, to say which of us "uncultured" nations could eat and which would do without our meals. Since making this beginning, however, we have read about a dozen papers on potash and several prospectuses of proposed potash producers, all of which have taken great pains to quote the professor and generally to show him the error of his ways; hence I have recast my introduction and will only refer to Ostwald's remarks by saying this: I know of some millions of dollars which would be invested in establishing a potash industry in this country if we could be sure Germany would be inclined to exact stiff terms from the United States, or dictate that she should go hungry. The thing which keeps this money out of such an investment is the fear, not that we won't have potash from Stassfurt as heretofore, but that we will have too much and that the German producers will be so glad to get Yankee dollars to pay their war debts that they will offer us potash on the same old $40 basis.

If the American investor after the war can be insured against the dumping of German potash salts into this country at prices too low for us to reach, I know that we can develop a potash industry in this country and in Canada which can more than take care of our needs for both agricultural and chemical purposes, and which can sell potash at a price which will work no hardship on any users. It is my purpose in this paper to outline the sources from which it seems most promising to produce American potash.

The present methods employed for obtaining potash in this country may be grouped under four general heads.

1. By the evaporation of the brines from various lakes and marshes.

2. From kelp and the ashes of various plants.

3. As a by-product of various industries, chief of which are the cement, iron, beet sugar, and molasses industries.

4. By the decomposition of silicate rocks, chief of which are alunite, glauconite and feldspar. Numerous other silicates are also available, among which are leucite and sericite.

BRINES AND LAKES

It is natural that the first attempts to obtain potash in this country were connected with the evaporation of brines from various lakes in the western part of the country. Geological Survey reports, even before the war, had called attention to the large amount of potash contained in the waters of some of these lakes, notably Searles Lake, in Southeastern California, which has been made the subject of extensive investigations on the part of the United States Geological Survey. The American Trona Corporation was organized in 1913 to exploit this lake, and had planned to spend something like $3,000,000 to build a railroad and to install the

[1]A paper read at the Buffalo Meeting of the American Institute of Chemical Engineers, June 22, 1917.

necessary machinery to recover borax and potash from this water. At that time, particular stress was laid on the borax rather than on the potash.

Searles Lake is located in the extreme northwestern part of San Bernardino County in southeastern California about thirty miles from the Southern Pacific Railway, at Searles. It consists of a dry bed of crystalline salts, hard enough to support a wagon and team. It occupies an area of from eleven to twelve square miles and has a depth of approximately 70 ft. The deposit contains a saturated brine in the interstices between the crystals, estimated to be 25 per cent of the volume of the bed, and carrying approximately 2.1 per cent potash (equivalent to 4 per cent potassium chloride) and about 1.3 per cent borax. An analysis (W. Van Winkle) of the solid matter from the water is given below:

	Per cent
K	6.34
Na	33.80
Cl	37.04
SO_4	13.00
CO_2	7.24
B_4O_7	2.50
Other constituents	0.08

By reference to the analysis above, it will be seen that the principal products obtained are potassium chloride, borax, soda ash, salt, and sodium sulphate. Of these products the salt will be largely in excess of all others.

I understand that the American Trona Corporation has expended $2,500,000 to date in developing this property, of which $600,000 has been spent for the construction of a 30-mile railroad connecting the lake with Searles, on the Southern Pacific Railroad. The company has built two plants, one at Trona, where the brine is evaporated, and the other at San Pedro, Cal., where the solid salts obtained from the evaporation are separated.

The American Trona Corporation has shipped quite a large quantity of potash in the past year. I understand that from the chemical standpoint, an objection is raised to their product owing to the sulphates and borax which it contains, and I am also informed that the fertilizer people have objected to the product on account of the borax.

There are numerous small lakes in the region of the Sand Hills of Nebraska, the waters of which are more or less alkaline and also contain potash. This potash is believed to have resulted from the leaching of the ashes from numerous forest fires which have occurred in that section. The larger and deeper of these lakes are only slightly alkaline and the only ones which are at all rich in alkali are the small lakes.

The Potash Products Company, of Omaha, Neb., has been for some time a producer of potash which they obtain by evaporating the water from Jesse Lake, situated in this section. This lake covers 240 acres and is located 300 miles west of Omaha, and 3 miles from Hoffland. The lake is underlaid with a dark greenish-colored mud, beneath which is a sand bed 20 ft. thick, strongly impregnated with brine of greater concentration than the surface waters. This brine contains about 13 per cent solid matter, of which from 25 to 30 per cent is soluble K_2O. The Potash Products Company has a capacity of about 75 tons of dry salts daily, their product will probably average 28 per cent K_2O, so their total output is approximately 21 tons of K_2O per day. No attempt is made to separate potash from the other salts, and the material is shipped as evaporated. The potash is in the form of carbonate, and the product also contains a large quantity of the carbonate of soda.

Other small lakes are being developed by the Hord Alkali Products Company of Lakeside, Neb.

The officials of this company inform me that it owns about 50,000 acres of land in which these alkali lakes are located, but that their development work has been carried only a year in advance of their requirements. This company began construction of an evaporation plant about a year ago, and started operation Jan. 1, 1917. Their plant has a capacity of from 40 to 50 tons of product per day, working on brine of about 1.075 sp. gr. This brine is pumped from wells located in lakes, the surface water of which is comparatively fresh (containing less than 1 per cent of solids). The plant itself is located on the main line of the C. B. & Q. R. R. at Lakeside. It is equipped with triple effect evaporators for preliminary concentration, and single effect for the salting out. The concentrated salts are fused to a clinker in a small rotary kiln, ground in a Stedman disintegrator, and packed in sacks of approximately 200 lb. each. The product has the following general composition:

	Per Cent
Na_2O	33.30
K_2O	21.82
SO_3	16.98
Cl	4.22
CO_2	21.87
Loss on ignition	1.50
Insoluble in water	1.25
	100.94

This region is entered by the Chicago & Northwestern R. R. and by the Chicago, Burlington & Quincy R. R., so that the transportation facilities are excellent. Unfortunately the supply of brine in these lakes is very limited. It is estimated that Jesse Lake, the largest of them, contains approximately 28,000 tons of K_2O.

There are a number of other companies throughout the west who are experimenting on the production of potash from brines. One of these companies is the Inyo Development Company, who has a small experimental plant and are planning to develop the potash resources of Owens Lake.

Owens Lake is situated south of Mt. Whitney and northeast of Death Valley, Cal. The lake is 27 miles long and 23 miles wide, and is estimated (H. S. Gale) to contain 3,000,000 tons of potash. An analysis of this water is given below:

	Per Cent
NaCl	39.51
Na_2CO_3	41.34
$NaHCO_3$	4.41
K_2CO_3	2.21
Na_2SO_4	12.06
Other constituents	0.16

Several thousand tons of soda ash have been made at Owens Lake, and it is proposed to recover the potash

from the spent waters from the soda ash manufacture. These waters were formerly wasted and contained about 4.25 per cent K_2O in the form of carbonate.

Another lake which it is proposed to develop but towards which I believe no material steps have been taken at the present time—is Summer Lake, in Oregon. This is about 30 miles from Pleasant View, Ore. The water is very similar to that of Owens Lake as will be seen from the analysis below:

	Per Cent
NaCl	27.10
Na_2CO_3	43.91
$NaHCO_3$	21.41
KCO_3	3.63
Na_2SO_4	2.21
Other constituents	0.87

There has been some attempt to develop a potash industry in connection with the Great Salt Lake, in Utah. The Utah Chemical Company is reported to be erecting a plant to make potash from the bitterns obtained as a by-product from the manufacture of solar salts from the waters of the Great Salt Lake. This plant is largely an experimental one.

By referring to the above it will be seen that practically all of the above developments during normal times would be limited largely by the capacity of the plant to get rid of other products than potash. There is also the objection that none of these waters will yield potassium chloride without treatment with reagents. The Nebraska Lake propositions, which would promise most under normal conditions and which are reported at the present time to be making a large amount of money, are quite limited as to brine supply and unquestionably they could only furnish a very small part of the potash which has been shipped to us from Germany.

The developments at Searles, Owens and Summer Lakes will depend almost entirely on the Pacific Coast market for soda ash and salt cake, and it is hardly probable that under normal conditions the market in that section will be sufficient to dispose of any very considerable quantity of these products. In the case of both Owens Lake and Summer Lake, the quantity of soda to be disposed of is so very much larger than that of potash, that they probably would never amount to anything more than very small potash producers. Against Summer Lake is also the difficulty of transportation and of obtaining labor, and the high cost of fuel.

The nearest soda ash plant is at Hutchison, Kan., but it is probable that this latter plant would cut them off from any trade East of the Pacific states, so that their market for soda ash would be almost entirely confined by adverse freight rates to the Pacific Coast. Even when it came to shipping potash to the East, they would have a very considerable freight rate (about $6.00) to overcome.

KELP

The fact that the giant kelps of the Pacific Coast are rich in potash has long been known. As early as 1911, kelp was gathered and dried by the Pacific Mulch Company, Terminal Island, Cal., but no effort was made by this company to do anything more than harvest the kelp, partially dry it, and chop it into pieces from 6 in. to 8 in. long. In the 1913 *Mineral Resources* the United States Geological Survey reported that a number of companies had been formed to engage in the kelp industry. At that time, however, no effort was being made to extract potash salts from kelp, and attention was entirely devoted to the harvesting, drying and grinding of the kelp.

I believe that the American Potash Company was formed prior to the war and was the first company actively to attempt the production of potash from kelp. This concern had a plant at Long Beach, Cal., where they harvested and dried kelp, using an oil-heated rotary dryer for the latter purpose. Some dried kelp was sold as such, while the rest was burned in a reverberatory furnace, the potassium chloride and sodium chloride leached out of the ash, and separated from each other by fractional crystallization. The American Products Company, Pasadena, Cal., later bought the effects of the American Potash Company, and moved to the property of the latter. This new concern was said to be financed by Mr. George Simmons, of the Simmons Hardware Company, St. Louis, and it was reported that their main idea was to carry out a process worked out by Mr. Isaac Naylor, in which the kelp was to be so treated that a celluloid composition for knife handles, etc., would be the main product, and potash would be obtained as a by-product. Little information is available as to the operations of this company.

Swift & Company, of Chicago, leased a small plant at San Diego and are harvesting and drying kelp. They make no effort to extract the potash, but are simply drying the kelp and shipping it to their fertilizer factories in the East, where it is used in the manufacture of mixed fertilizers. This plant is interesting as it is said to represent the best methods yet tried for drying kelp mechanically. The old plant consisted of two rotary dryers, one 54 in. in diameter by 35 ft. long, and the other 60 in. in diameter by 40 ft. long. The wet material was fed into the cold end of the larger dryer, dropping out from the hot end, and was thence conducted by a belt conveyor into the hot end of the small dryer, leaving the latter at the cold end. The product, which contains 10 per cent water, is ground in a swing hammer mill, and sacked. The dry product contains the whole body of the kelp (including the nitrogen) and averages 15 per cent water-soluble K_2O. Swift & Company have now built a large plant containing ten direct heat dryers, 60 in. in diameter by 40 ft. long, employing crude oil for fuel. The buildings are of steel; electric drives and modern equipment are employed throughout. The plant is designed to treat 200 tons of wet or 20 tons of dry kelp per day.

The Hercules Powder Company have the only large plant on the Pacific Coast at the present time for actually obtaining potash salts from kelp. Their plant is located at Chula Vista, Cal., and represents a splendid example of chemical engineering ingenuity, although it is probably only a war-time proposition. The products obtained are potassium sulphate and acetone. The kelp is harvested by machinery and is ground by the harvesters to a thick, viscous mass. This latter is pumped into digestion tanks and fermented, whereby the slime and other organic matter form into acetic acid. This acetic acid is neutralized with calcium carbonate and converted into sodium acetate by sodium sulphate. This latter is a waste product from the ace-

tone plant. The liquid is then evaporated and the sodium acetate crystallized out. The potash is obtained 80 per cent pure, while the sodium acetate is recrystallized and then used in the manufacture of acetone. This plant is handling about 1500 tons of wet kelp per day, obtaining from this about 18 tons of potash and 24 tons of acetic acid. The process of clarification, sedimentation, etc., is very similar to that used in sugar manufacture.

The U. S. Department of Agriculture is now investigating with a full-sized plant the possibility of the destructive distillation of kelp. The products obtained are gas, tar, ammonia, iodine, charcoal and potash. The gas will be used to heat the retort, and the potash will be leached from the charcoal.

The possibilities of the production of potash salts from kelp on a large scale do not seem to be particularly bright as a post-wartime proposition. The artificial drying of the kelp represents a large undertaking, since 20 tons of potash require handling something like 1500 tons of wet kelp, containing 1350 tons of water. The plant required to conduct such a large drying operation is considerable, and the type of rotary dryers employed seldom show an efficiency of more than 70 lb. of water per gallon of oil burned, or about 38,000 gal. of oil for 1500 tons of kelp. The cost of this amount of fuel alone under ordinary conditions would eat up most of the price obtained for the product. With destructive distillation and the employment of the gas to help heat the retort some saving in fuel could be effected, but we doubt if this saving would prove very considerable. We also doubt the value of the charcoal. After the potash had been leached from it, this charcoal would unquestionably contain considerable water, and if it is anything like the similar residue obtained in the paper industry, no use could be found for any considerable quantity.

The manufacture of acetone from kelp is manifestly a war time industry, so that potash as a by-product from this industry is not likely to survive the need of acetone for making smokeless powder.

BY-PRODUCTS OF OTHER INDUSTRIES

It has long been known that potash was among the volatile products passing off in the waste gases from a number of furnaces, notably from the rotary cement kiln and from the blast furnace. The writer made some experiments as far back as 1903 at the plant of the Dexter Portland Cement Company, to determine the effect which the ash of the fuel had on the cement, and particularly the percentage of ash which entered the cement during burning. Among other things which were disclosed by this investigation, was the fact that there was a considerable proportion of both potash and soda volatilized in the rotary kiln. My investigations at that time were made on a 6-ft. x 60-ft. rotary, and I found that approximately 50 per cent of the potash and about 25 per cent of the soda was volatilized. The results of the writer's experiments were given in a paper read at a meeting of the American Association of Portland Cement Manufacturers, at Atlantic City, in the summer of 1904, and also in his work "Portland Cement."

About this time Professor Hillebrand, then of the U. S. Geological Survey, found that the raw material contained relatively much more potash than the cement, and he therefore assumed there must be some loss of potash in the burning of cement.

Mr. Clifford Richardson read a paper at the 1904 meeting of the American Society for Testing Materials, in which he proposed to the cement industry that they collect the potash lost by means of a water spray, and stated that Dr. Hillebrand had applied for a patent upon such a process. We believe, however, that no patent was ever granted. The matter was discussed informally, but it was generally conceded at that time that the cost of collecting this dust with the apparatus then known, namely, water sprays, would far exceed its value, if indeed it could be collected at all.

In southern California there had been considerable opposition from the orange growers to the cement plants owing to the dust which settled on the orange groves. It was claimed that this reduced the value of the fruit. Numerous suits were started, and in order to appease the orange growers the two plants near Riverside undertook to eliminate the dust. The California Portland Cement Company in 1911 installed a system of dry settling chambers followed by water scrubbers at their plant at Colton, and the Riverside Portland Cement Company in their plant near Riverside installed even prior to this a Cottrell electrical precipitation treater, which latter was then largely in the experimental stage. The Riverside people persisted, however, in the use of this treater, and gradually developed it into a very efficient method of catching the dust. By this means they were able to recover 95 per cent of the dust formerly lost from the kilns. It was found that in this dust was from 80 to 90 per cent of the potash volatilized in the kiln. Unfortunately, however, the raw materials at that time in use at Riverside were quite low in potash and the dust obtained from the last part of the treaters averaged only about 4 to 5 per cent potash and that from the first part materially less than this, practically all of which was soluble in water.

In order to obtain a material richer in potash all of this dust was fed to a supplementary kiln and was burned to cement in that kiln. From this kiln, dust was obtained running in excess of 30 per cent K_2O, but it was found that most of the potash in the dust fed into the kilns did not volatilize but remained with the clinker, due no doubt to the fact that the potash was present in the dust as sulphate.

When fertilizer companies began to purchase low-grade material for potash, one of the first substances which attracted their attention was the crust which collects on the side of the stacks of the rotary kiln, and which falls down at intervals into the dust chamber, its high potash content having been pointed out by the writer in the paper mentioned above and also in his work on Portland cement. They persuaded a number of the cement manufacturers to save this crust, which they purchased at prices ranging from $1.50 per unit in the early days of the war to $3 per unit later on. This dust averaged 6 to 8 per cent of water-soluble potash.

The Security Cement & Lime Company are among the cement companies who sold their flue dust. They were located near the heart of the fertilizer manufacturing district. Their manager, Mr. J. J. Porter, after seeing the installation of the Cottrell system at the first chemical show, was very much impressed with the possibility of catching all of the dust from the stacks. He re-

turned home and made investigations which demonstrated that they could expect to obtain quite a high percentage of potash in this dust. He then visited Riverside and investigated the process there, and as the result of his investigation persuaded his company to install the Cottrell process, not with a view of eliminating the dust—as they were meeting no trouble from this source—but with a view to catching the wasted potash. Their plant was put in operation in the summer of 1916. Numerous difficulties were encountered at the beginning, most of which have been satisfactorily eliminated.

One very peculiar situation presented itself which had not been foreseen. At the plant of the Riverside Portland Cement Company at Riverside, practically all of the potash in the dust was in the water-soluble condition. When the treaters were put in operation at Security, it was found that only a little more than half of the total potash in the dust was water-soluble, and that while the dust contained from 12 to 15 per cent total potash it contained only about 6 to 7½ per cent of water-soluble potash. The only explanation which could be offered to account for the difference in the state of the potash at the two plants is that at Security the cement is burned with pulverized coal and at Riverside with oil. It appears, therefore, that chemical combination takes place between the products of combustion and the potash.

It is found, however, that all of the potash in the dust may be dissolved by prolonging the digestion with the hot water and by digestion under high pressure. It is also readily soluble in acid. In making mixed fertilizers with this dust, it was found that a considerable portion of this potash was rendered soluble when the dust was mixed with acid phosphate.

It has, of course, been known that chlorides will increase the volatilization of potash. Numerous experiments were made at Security to increase the liberation of potash from the raw material and also to prevent its production in an insoluble form. One scheme was to inject sulphur dioxide into the kiln. The plan, however, which has proved most successful, is to introduce a small amount of salt with the raw material and also with pulverized coal. When the treater was first placed in operation the average water-soluble potash in the dust was about 6 per cent, but since the introduction of the salt the quantity has been increased to 8½ per cent. Patents have recently been granted to Huber and Reath (Nos. 1,194,344 and 1,219,315), who propose to use calcium fluoride in place of salt. They claim that the latter is entirely recovered by the treaters so that only a very small quantity of this mineral is needed, the original charge passing around in a cycle as it were. This process is in use at the Riverside plant, and it is claimed 90 per cent of the potash is volatilized where it is used.*

The installation at Security was followed by one at the Duluth plant of the Universal Portland Cement Company with a view of eliminating dust only. At this plant very little potash is obtained, and I believe no effort is made to market the dust. This is due to the fact that slag (which here takes the place of the clay element of the cement mixture) contains practically no potash.

*This process has been fully discussed in this journal, Vol. XVI, June 15, 1917, page 701.

At the Alpha Portland Cement Company the waste gases from the kilns are first led through water-tube boilers and thence into Cottrell treaters. At this plant the percentage of potash in the dust is very low, containing about 8 per cent total potash, while only about 2½ per cent of this is water-soluble. It was found that the percentage of water-soluble potash was increased very largely by the use of salt, but, unfortunately, this salt collected on the tubes of the boilers and interfered with the steaming properties of the latter, so that this addition is no longer made at this plant.

The Santa Cruz Portland Cement Company, Santa Cruz, Cal., have been experimenting for the past ten months with one of their kilns, and have been making nearly 700 lb. per day of potassium sulphate, 80 to 90 per cent K_2SO_4. The details of their process are not now for publication, but they do not employ the Cottrell dust precipitation system. They state that they consider their process a success and propose shortly to install their system on all their kilns.

At the present time installations of the Cottrell system are being made at quite a number of plants with a view of obtaining a dust high in potash which can be sold to the fertilizer trade.

The soda as well as the potash is volatilized to some extent, so that the dust will contain some water-soluble soda. Usually the proportions are about 1 to 4 or 1 to 3. When salt is used in the raw materials the proportions are much smaller.

As we said in the earlier part of this paper that practically all the potash in this dust could be slowly extracted with water, it is highly probably that *all* of the potash in this material is available for plant food. In addition to the potash this material is rich in lime, therefore we have in this one material two very valuable fertilizer ingredients—lime and potash.

At the present time the fertilizer men are perfectly willing to take this dust carrying as low as 4 per cent K_2O, but it is extremely doubtful if they will accept it after the war is over and they can get German potash. The objections to the dust are twofold: First, it is of course highly alkaline, containing both calcium carbonate and oxide. When used in mixed fertilizers in large quantity the lime reverts the phosphoric acid to the insoluble form. Second, the dust is too low in potash to permit using it in fertilizers to contain more than 2 per cent K_2O. Two alternatives suggest themselves—one to educate the farmer to the use of this material *as such*, and the other to extract the potash by leaching and evaporation and market the salt as chloride or sulphate. The latter method has been worked out by Messrs. Huber and Reath at the Riverside Portland cement plant, and is described in the reference given above.

In addition to the experiments mentioned above, the writer has been able to examine samples of raw materials and clinker from some half dozen different plants since the European war. All of these samples show a loss of potash ranging from 1¾ lb. to 2½ lb. per barrel of cement burned, an average of about 2 lb. per barrel. It should be remembered that not all the potash so obtained, however, is water-soluble, but it is all available for plant food, and undoubtedly methods of leaching out the same can be easily worked out if found necessary. The efficiency of a Cottrell treater will range between 95 and 98 per cent of the dust and 80 to 90 per

cent of the potash. When no treaters are installed the dust losses range from 3 to 5 per cent of the raw material introduced into the kiln.

At the present time the loss of dust at the average cement plant is probably in the neighborhood of 3 per cent, or 18 lb. of dust per barrel of cement. If 95 per cent of this dust and 80 per cent of the potash were recovered, dust would be obtained having approximately 9 per cent potash. Assuming that there could be recovered 1.6 lb. of potash per barrel of cement there would be produced from the cement industry alone 72,000 tons of potash (figured as K_2O) per year, or nearly one-third of the before-the-war importations from Germany.

The Bureau of Soils, Department of Agriculture, is at the present time preparing a very extensive report on the potash possibilities of the cement industry, and this report covers the subject of the losses of potash at various plants very completely.

About the time of the beginning of the European war, I made a number of experiments in a small kiln, 2 ft. in diameter x 20 ft. long, to ascertain the possibilities of obtaining potash as a by-product from the cement industry, using feldspar, limestone and iron ore as the raw materials. If iron ore is not used, white cement would be obtained, but it was our idea to come as near as possible to producing the product of most of the cement mills.

These experiments followed two general lines. At first we furnaced at about 800 deg. C. a mixture containing salt or calcium chloride and lower in lime than would be used for cement, leached the resulting soft brown clinker with hot water to extract the potash, mixed sufficient limestone with the residue to make a proper cement, ground, and burned the mixture to cement. The second line of experiments consisted in making up a proper mixture for cement and burning it directly to cement, volatilizing the potash in so doing. We met with a fair degree of success along the second line. With the first process a number of difficulties were encountered. One was that with the best treatment we could give we could not render soluble more than about 60 per cent of the total potash in the feldspar, and that we lost some by volatilization. We found on analyzing the commercial side of the case that it seemed to be a much better proposition to attempt to volatilize all of the potash and make a cement clinker at one operation, particularly as we were able to volatilize about 70 per cent of the total potash, whereas we were never able to render more than 60 per cent of it soluble in the two-stage process. Furthermore, it required very little additional fuel to produce a cement than it did to produce the lighter burned material, and with the latter there was of course the extra fuel needed to burn it to cement. Owing to the large amount of water in the leached material this latter operation required more fuel than would be required to manufacture cement in the first place. To render the potash soluble we also had to use a considerable portion of either salt or calcium chloride, whereas if volatilized we used only a very small quantity. As an example of what we did along the line of volatilizing the potash take the following example: A mixture was made up of three raw materials, limestone, feldspar, and iron ore of the following composition:

	Limestone Per Cent	Feldspar Per Cent	Iron Ore Per Cent	Mix Per Cent	Cement Per Cent
SiO_2 ...	1.02	68.12	16.20	13.40	20.80
Al_2O_3 ...	0.40	19.05	1.88	3.78	5.86
Fe_2O_3 ...	0.42	1.15	71.98	1.98	3.07
CaO ...	52.20	0.51	0.25	41.77	64.60
MgO ...	1.51	0.47	1.65	1.25	1.94
K_2O	0.21	8.52	0.25	1.69	0.80
SO_3	...	...	...	...	1.65

These three materials were mixed in the following proportions:

Limestone	800 lb.
Feldspar	180 lb.
Iron ore	20 lb.

These gave a mixture of the analysis shown in the fourth column, and the final cement had the analysis shown in the fifth column.

This cement was found to have excellent physical properties and to compare favorably with any cement at the present time on the market. It was normal in every respect and would have been accepted by any engineer as first-class material.

By referring to the analysis it will be seen that the raw mixture contained 1.69 per cent of potash. As it takes 600 lb. of raw material to make a barrel (400 lb.) of cement, there were charged into the kiln 10.14 lb. of potash for each barrel of cement produced. As the clinker contained 0.80 per cent potash, there was in each barrel of cement 3.20 lb. of potash, making a loss by volatilization of 6.94 lb. per barrel. Assuming a dust loss of 3 per cent or 18 lb. per barrel, this dust should contain 38.56 per cent K_2O.

The potash volatilized at various plants, as I have said, varies quite widely, ranging from 1.5 to 2.5 lb. At plants where the former amount is lost, recovery would probably give a dust too low in potash for sale in this form. At such plants recovery would have to be followed by leaching. Experiments which we have made convince us that this can be successfully done if proper means are installed. This would give a dust which could be used in the kilns and the potash would be in the form of a salt running 60 per cent to 80 per cent K_2SO_4.

It should also be borne in mind that there is always the possibility of increasing the liberation of potash by selecting raw materials high in potash. No doubt in many localities a change of clays from one low in potash to one higher would bring about the desired result. In many localities feldspar and sericite are available and might be mixed with the clay without detriment to the cement. Indeed, as I have indicated above, feldspar and iron ore might take the place of clay, or, if a white cement is desired, feldspar alone might be used. At the Riverside plant, feldspar is mixed with the shale to increase the potash in the raw material burned.

The possibilities of developing a paying potash industry in connection with the manufacture of cement are excellent. Unfortunately for the speedy establishment of such an industry, the very high cost of steel plate and structural steel at the present time will undoubtedly keep many manufacturers from installing plants who would otherwise do so. The question, too, is not alone one of price, but also of deliveries. No

manufacturer would care to pay the present high price of steel without assurance that he would also enjoy the present high price for potash. Under normal conditions a treater plant for precipitating the dust from a 3000-bbl.-per-day cement mill will cost about $190,000 complete, or 10 cents per barrel of annual output, but at the present time the cost will be fully twice this amount.

The dust question has always been one of more or less annoyance. The chance to settle this thing once for all and at the same time obtain a valuable product will certainly appeal to the cement industry. In addition to the Cottrell treaters, I believe that most manufacturers will also install boilers after their kilns to save the waste heat from the latter, which is normally more valuable than the potash. The two installations work very nicely together, as the flues, dampers, fans, etc., of one installation will serve for the other, and the boilers will cool the gases enough to permit the use of very much smaller treaters, since the size of the treaters required is proportional to the volume of gases to be cleaned. The normal cost of boilers and treaters will be about 15 to 18 cents per barrel of annual output, but from 30 to 35 cents per barrel at present prices.

If many cement manufacturers would install boilers and treaters now, even with the present high cost of materials, and could sell their potash for $3 per unit for one year, they could pay for their plants.

I estimate that it would cost at present prices approximately $30,000,000 to equip all the cement plants in this country (where such installations would pay) with boilers and treaters, and that for this outlay we would save annually, even in normal times:

72,000 tons of K_2O at $80 per ton.....	$5,760,000.00
2,400,000 tons of coal at $3 per ton.....	7,200,000.00
Total saving.....	$12,860,000.00

Even after deducting the cost of operation, upkeep, etc., this would pay a very handsome interest on the investment.

The loss of alkalies in the blast furnace has been known for many years, but no efforts had been made to recover potash up to the outbreak of the war. Mr. R. J. Wysor, then chief chemist but now superintendent of blast furnaces of the Bethlehem Steel Company, had analyzed the dust from the bottom of the stove checkerwork and found it to contain 15 per cent of water-soluble K_2O. Attempts to sell this material prior to the war failed, but with the demand induced by the war it was found readily salable and has been collected and sold ever since.

Mr. Wysor has since that time made a very extensive study of the possibilities of potash recovery from the blast furnace gases at Bethlehem. The result of his investigation is given in a paper read at the February meeting of the American Institute of Mining Engineers in New York, abstracted in our issue of Feb. 15, 1917, Vol. XVI, page 205, and most of the information given below is taken from his paper.

The ores used by the majority of iron manufacturers range from 0.21 to 0.33 per cent K_2O. Some of the Southern iron ores contain much more, but generally speaking these are high in clay and hence would naturally contain feldspar. Coke generally contains about 0.25 per cent K_2O, and limestone varies from 0.1 to nearly 1.0 per cent K_2O. The impure limestones high in clayey matter usually contain most K_2O, and dolomites, generally speaking, are higher in K_2O than are calcites.

Wysor found in the Bethlehem charge 32 lb. of potash per ton of pig iron produced, of which about half came from the ore and a quarter each from the limestone and coke. He found that 20 per cent of the potash remained in the slag, and hence 80 per cent was volatilized, of which the wet scrubbers remove 58 per cent, it going into solution in the water used to wash the gases. The solution is too dilute, however, to permit of the recovery of the potash by evaporation. Wysor estimates that it is possible to recover about half of the total vaporized potash by dry cleaning the gases, using a Cottrell treater instead of the wet washers. Up to the present time only about 4 per cent of the total potash has been recovered and sold, yet the amount of dust so recovered in fifteen months has amounted to 106.3 net tons of K_2O. It represents only the dust most easily collected at the stoves, boiler flues, and dust catcher. This dust averages about 9.9 per cent water-soluble potash. The dust, unlike that from the cement industry, is not highly alkaline. It is probable that after the war leaching would have to be resorted to.

As in the cement industry, certain advantages other than the recovery and sale of the product are connected with the removal of the dust from the gases, notably the better cleaning of the gases. It seems very probable that the dry method of cleaning will replace the wet method at many furnaces. This would result in the saving of much potash. Assuming a recovery of 10 lb. of potash per ton of pig iron, and an annual production of 25,000,000 tons of pig iron, the annual potash resources of the iron industry would be 125,000 tons of potash, figured as K_2O.

Our former imports from Germany averaged about 250,000 tons of K_2O annually, so it will be seen that the cement industry and the iron industry alone might be developed to produce nearly 200,000 tons annually.

The cost of operation of the dry treaters would probably prove less than that of the wet washers now used for cleaning blast-furnace gases, so that the only added cost of potash recovery would be the labor of collecting the dust, leaching, etc., and the fuel for evaporation of the liquid and for drying the salt, which items would be about the same as for cement-kiln dust.

The production of potash from the waste liquor of beet sugar manufacture, molasses, etc., has been treated of in a paper which has been read at the Buffalo meeting of the American Institute of Chemical Engineers, June 22, 1917, and published in Metallurgical and Chemical Engineering, Vol XVII, July 1, 1917, page 17, so that it is hardly necessary for me to go into this subject at this time. It is estimated that about 2000 tons of potash (figured at K_2O) are now being produced annually from this source, one of the largest producers being the Western Alcohol Products Company of Agnew, Cal., and it is said that their output is larger than that of any of the kelp plants on the Pacific Coast.

POTASH FROM SILICATE ROCKS

The production of potash from silicate rocks has been the subject of much chemical investigation, and the patent offices of England, Germany and the United States have granted many patents on processes looking

toward this end. One of the oldest of these was granted to F. O. Ward and F. Wynants (English patent No. 3185) in 1857. This process is said to have been tested at that time on a large scale and to have given satisfactory results. It consisted in finely grinding and mixing feldspar, flourspar, and chalk, and after molding the mixture into balls or cakes, heating them to a yellowish red heat. A porous clinker was obtained which on leaching with hot water gave up its alkali. It is interesting to note that Ward, even at that time, proposed to use the residue from which he had leached the potash for the manufacture of hydraulic cement.

It is quite natural that the chemical principles made use of by Prof. Lawrence Smith to attack silicates in his method for determining the alkalies, should have been the subject of much investigation looking toward their application to the liberation of potash from feldspar and other silicates on a large scale; and many patents have been granted making use of the essentials of his methods, but varying the reagents and procedure so as to apply more directly to practical work.

One of the earliest of these patents was that granted to Rodin (U. S. No. 641,406). He used a mixture of powdered feldspar, salt, and lime. This patent has been followed by a large number of others granted for various modifications of the same general scheme in which gypsum, calcium chloride, and other haloid compounds took the place of the salt. Nearly all of these processes make use of lime in connection with the above reagents.

Along a somewhat different line we have another series of patents, the first of which was issued to A. J. Swayze in 1905 (No. 862,676). He proposed to fuse feldspar, gypsum, coal, or coke, in a blast furnace, whereby potassium sulphates would be volatilized. Other patents along this line are those issued to H. E. Brown (U. S. Nos. 1,123,841, 1,123,864 and 1,124,238). Just recently there are a whole series of patents issued to A. C. Spencer and to Spencer and E. C. Eckel, covering the volatilization of potash and the production of hydraulic cements (U. S. Nos. 1,209,220, 1,209,219 and 1,209,135).

In addition to the above general line of patents we have many in which novel methods of attack have been proposed, and in which various valuable by-products would be obtained which would assist in paying for the process.

It has generally been conceded that to make potash from feldspar alone was an almost impossible undertaking under normal conditions and pre-wartime prices for potash. The reason for this may be readily understood when we take into consideration that feldspar as ordinarily mined, without careful sorting and selection, very seldom runs over 10 per cent potash and frequently as low as 8 per cent. At a price of 80 cents a unit, this would allow only $6.40 to $8 for the mining or quarrying of the feldspar, its crushing and grinding, the reagents which are to be used with it and the fuel and labor necessary to liberate the potash. In view of the fact that it is generally conceded that feldpsar mining will cost approximately $2 per ton, we have only $4.40 to $6 left to carry on the rest of the process and to furnish overhead and profits.

A very much cheaper source of potash than feldspar is the green sand or glauconite of the Atlantic Coastal Plain. The deposits of this mineral are very extensive and the quantity obtainable is probably greater than that of any potash mineral. My own observations of the New Jersey field has convinced me that green sand can be found in many localities in New Jersey containing as much as 6 per cent potash. These beds range from a few feet to 20 ft. in thickness. They are covered with very little overburden and the material can be dug with a steam shovel just as cheaply as sand can be obtained. I estimate that 10 cents per ton will cover both the stripping and the digging of the green sand. In addition to this, there are extensive deposits of lime-sand or marl adjacent to the green sand beds. These latter contain about 75 to 85 per cent carbonate of lime, and about 0.5 potash. In many instances the lime-sand overlies the green sand. These deposits are also located in a region where fuel is fairly cheap, where transportation facilities are of the very best, and where labor and living conditions are good. In view of these facts, it seems to be much more probable that potash can be produced directly from green sand at a profit rather than from feldspar.

Alunite has been largely exploited as a source of potash and is being used for that purpose now. It is, however, found as yet only in Utah. This deposit is comparatively small and is largely under control of a few people. It seems hardly probable, in view of the slow progress which has been made to date, that this will ever be the source of anything more than a local potash industry.

This applies to most of the other silicates, such as leucite and cerisite, all of which can be treated along the lines of attack proposed for feldspar and glauconite.

Considerable experimental work, some of it on a large scale, has been done on those processes in which lime and a chloride are mixed with feldspar or green sand and the mixture ground, furnaced, leached, and the resulting liquor evaporated. Mr. W. H. Ross of the Bureau of Soils published a very interesting paper along this line in 1912, giving the results which he was able to obtain by heating together a mixture of feldspar, limestone and either calcium chloride or salt. He found that unless he used quite a large proportion of lime and chloride that his yields were low. His best results being obtained on a mixture of one part feldspar, three parts limestone and one-half part calcium chloride, under which condition he obtained a yield of almost 95 per cent. But with a mixture of one part feldspar, one part lime and one-quarter part calcium chloride, he obtained a yield of only 60 per cent. Substituting salt for calcium chloride in the latter mixture, however, he obtained a yield of 68½ per cent.

Following along practically the same lines, and using a mixture of one part feldspar, one part calcium carbonate, and one-quarter part calcium chloride, and heating this mixture in a rotary kiln 2 ft. in diameter and 20 ft. long, I obtained a yield of 55 per cent potash. By substituting salt in place of the calcium chloride a slightly better yield was obtained. As the amount of lime was decreased from the above formula less potash was obtained. The more finely the mixture was ground the better results were obtained, but the best yield I could get with feldspar, lime and salt in the proportions given above was 73 per cent when the mixture was ground to a fineness of 98 per cent passing the 100-mesh sieve and 86 per cent passing the 200-mesh sieve. This was considered about the limit of economical grinding.

Substituting sericite for feldspar I obtained practically the same yield, but with glauconite I was able to obtain a much higher yield—in fact, all investigations which I have made lead me to believe that this mineral is very much more easily attacked than feldspar. With the glauconite-lime-salt mixture referred to above we have obtained yields as high as 85 per cent of the potash theoretically possible.

This is a very easy process to carry out. The operation of crushing and grinding the material have been well developed, and the furnacing can, of course, be done in a rotary kiln. No complications are experienced in this latter operation. The required temperature is low, and either producer gas, pulverized coal or fuel oil could be used. In my experiments I used the latter fuel for convenience. I do not believe any complication would arise from the use, however, of pulverized coal, and certainly not from producer gas. The material furnaces easily at temperatures varying from 800 to 1000 deg. C., depending on the composition of the mixture. No fusion takes place, the effort being made to produce a soft, porous clinker. This leaches easily without grinding, and 95 per cent of the soluble potash in it can be extracted with water. The amount of fuel required in the kiln is much lower than that required for the manufacture of cement, and certainly should not exceed for the dry process 250 lb. to the ton, and for the wet process 350 lb. to the ton. Any loss by volatilization can be taken care of by Cottrell treaters.

By leaching in series very strong solutions can be obtained so that the amount of water to be evaporated is cut down to a minimum. Potassium chloride can be easily separated from either calcium chloride or sodium chloride, and the latter can be returned to the kilns with the next charge.

On the other hand, if the sulphates are used, a difficult separation nearly always results. While there is probably less volatilization with the sulphates, there is much more difficulty experienced in obtaining a pure potash salt and, as it is well known, the chloride is the most acceptable salt for fertilizer manufacture.

Strange to say, very few attempts have been made to produce potash commercially by this process—possibly because it has not promised anything like the returns offered by some of those other processes in which by-products are obtained.

The Atlantic Potash Company recently bought out the plant of the old Northampton Cement Company at Stockertown, Pa., which had been standing idle for some time. They are operating under the patents granted to George F. von Kolintz (No. 1,201,396). This process consists in oxidizing the green sand and heating the same with calcium chloride without the use of lime. This plant is now in operation, and we understand that some potash has been produced.

Another method of liberating potash is covered by patents to S. Peacock, and consists in heating the finely ground mineral with lime under pressure in an autoclave, whereby the potash is made soluble and is leached out. The Waverly Chemical Company, Camden, N. J., has operated under Dr. Peacock's supervision, using green sand. They made some potassium carbonate which was sold to glass makers, but their operations have now been discontinued, presumably because they could not be conducted at a profit.

The Kaolin Products Company, Jones Point, N. Y., is using this same process in a small way, employing feldspar. They make a species of sand-lime brick from the residue. This brick, I am informed, is a very superior article.

Furman Thompson proposed to employ acid sulphate of soda and salt to attack feldspar (U. S. patent No. 995,105, and also No. 1,091,034, to H. P. Basset). Muriatic acid and salt cake are obtained as by-products. The Spar Chemical Company, Baltimore, Md., built a plant at Curtis Bay, Md., prior to the war, to produce potash by this method, but their efforts here failed, due largely to the difficulty of separating the sulphate of soda and potash.

Along the second line of patents referred to above (in which the potash is volatilized), we have the three granted to H. G. Brown, and covering the manufacture of potash and slag cement from feldspar. Brown proposes to fuse together limestone, feldspar and calcium chloride in a metallurgical furnace heated with coke. The potassium chloride is given off as a fume, which is to be collected by a Cottrell treater. The slag, which is tapped off, is to be mixed with slaked lime and ground into slag cement. The Buffalo Potash & Cement Corporation will operate this process. They have purchased the plant of the Niagara Cement Company in Buffalo, and expect soon to be ready to operate.

We also note in recent literature the organization of the Canadian Potash Corporation, which proposes to manufacture potash and cement along somewhat similar lines. They have purchased a crushing plant at Gravenhurst, Ont., where there is said to be a large feldspar deposit, and also a cement plant at Durham, Ont.

While we are disposed to criticise the cement end of these propositions so far as they anticipate making slag cement, the potash end looks entirely feasible, and if it can be operated independently of the slag cement production, it may be developed to any extent desired. Slag cement at the present time is not a very salable product, and we believe that practically all of those who first undertook its manufacture in this country have now abandoned it.

We now come to a series of patents most of which are dependent on some valuable by-product for their success with normal markets. For instance, we have the patent of Hart, in which barium carbonate, carbon and feldspar are heated together, and barium sulphate or other barium salts are obtained as by-products. The application of this patent is, of course, limited to the market for barium compounds. There are also a large number of patents in which aluminum salts are obtained as by-products. As there is about twice as much alumina as potash in feldspar, as ordinarily mixed, there would, of course, be a very large tonnage of alum or alumina to get rid of.

For instance, feldspar may average 20 per cent alumina and 10 per cent potash; therefore, for every ton of potassium chloride produced there would be possible 4¼ tons of dried aluminum sulphate, or 8¼ tons of dried alum. The amount of potash used in this country far exceeds the alum. If we consider the aluminum in feldspar on the basis of bauxite—the raw material for aluminum as well as alum, and of which the domestic production is about 225,000 tons annually—we can arrive at a better estimate as to the limitations of this field. Bauxite averages about 57 per cent

alumina, then the above amount is equivalent to 128,250 tons of alumina, which would take care of about 102,000 tons of potassium chloride or approximately 64,000 tons of potash.

I am informed that one experimenter is making brick of the residue from his leachings. This, of course, like the cement field, opens up a large market for the so-called by-product, especially since the brick is said to be of the highest quality.

In many of the processes proposed the quantity of potash is very negligible compared with that of the by-product, and under normal conditions its value is generally much less, so that with most of them potash is really the by-product and the other constituent the main one.

Summing up the situation, I believe that the largest future source of cheap potash available in this country is in the iron industry and the cement industry. Germany is reported to have $150 invested in her potash mines and equipment for every ton of potash produced annually. On this basis $37,000,000 would be needed to produce the 250,000 tons of potash imported into this country.

I believe that the expenditure of this amount of money in this country in these two industries alone would result in the recovery of potash now lost amounting to nearly 200,000 tons.

The balance could easily be obtained from the evaporation of lakes and brines, from beet sugar waste and from some of the processes now proposed for the manufacture of potash direct from feldspar or glauconite.

What is needed in this country to develop a potash industry is not research alone, but the feeling that when this industry is built up proper legislation will be enacted to prevent its being tumbled down by cut-throat methods from the foreign producer. While this might result in slightly higher-priced potash to the farmer, I fully believe that he will be justified in paying the higher price in order to be free from foreign dictation.

Baltimore, Maryland.

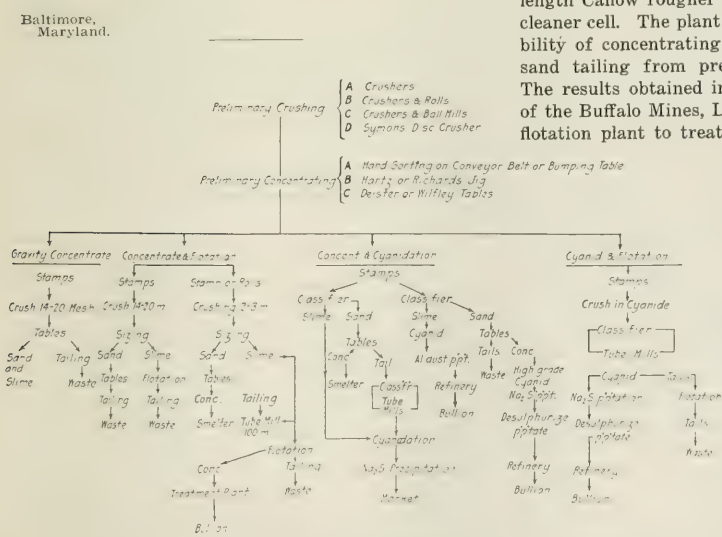

FIG. 1—MILLING PRACTICE COMPARISON IN COBALT DISTRICT.

Synopsis of Recent Metallurgical and Chemical Literature

Flotation

Present Flotation Practice on Cobalt Ores.—In the June, 1917, bulletin of the Canadian Mining Institute, pp. 544 to 553, is an article of considerable interest by J. M. CALLOW and E. B. THORNHILL on flotation as practised on cobalt ores. Flotation on a comparative commercial scale was first tried out by an experimental

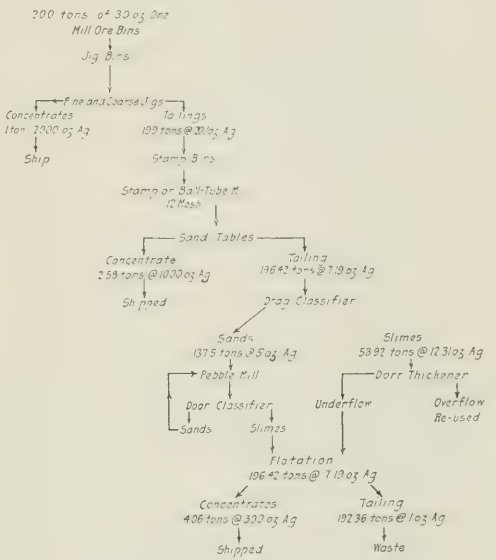

FIG. 2—COMPLETE MILL FLOW SHEET.

plant built and operated by the Buffalo Mines, Limited. This plant consisted of a two-compartment standard length Callow rougher cell and one one-half size Callow cleaner cell. The plant was built to determine the feasibility of concentrating the silver values in the stacked sand tailing from previous concentrating operations. The results obtained in this plant led the management of the Buffalo Mines, Limited, to erect a 600-ton Callow flotation plant to treat these tailings. This plant was put in operation in September, 1916. The McKinley-Darragh-Savage Mines soon followed with a second plant, of 200 tons daily capacity, and at the present time the Nipissing Mines, the Coniagas Mines, the Dominion Reduction Co., the Northern Customs Concentrators, and the National Mine, use the Callow pneumatic system of flotation.

Fig. 1 shows the milling practice at the different mills in Cobalt district at the present time. The flotation process has not replaced the standard method of gravity concentration, but its particular function is to save

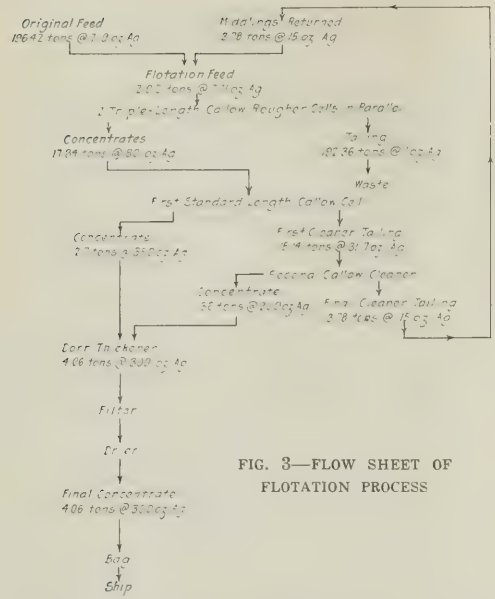

FIG. 3—FLOW SHEET OF FLOTATION PROCESS

the more friable silver minerals and fine leaf silver escaping from the gravity concentration. Fig. 2 shows the disposition of the flotation plant, and Fig. 3 indicates the treatment of the ore in the flotation plant proper.

The ore must be comparatively fine ground to liberate the contained values. The economic limit of grinding appears to be reached when not more than 1 per cent to 2 per cent is retained on a 100-mesh screen. Practically all the plants use mixtures of pine oil, coal-tar creosote, and coal tar; 15 per cent pine oil, 75 per cent coal-tar creosote, and 10 per cent coal tar gives an efficient mixture. At times, a mixture of 10 per cent pine oil and 90 per cent sulphur fuel oils gives satisfactory results.

The recovery of values by means of flotation varies over a wide range depending mainly on the product going to flotation, the grade of concentrate required and the experience of the operator. The most important item is the last one mentioned as it requires considerable time to produce an efficient operator. The average efficiency in flotation at the McKinley-Darragh-Savage Mines, Limited, is 82 per cent. The average headings at this mill runs 6.37 oz. and the tailing 1.14 oz. of silver.

With the exception of the Buffalo Mines, Limited, the companies producing flotation concentrates depend on the smelters in the United States for the disposal of their products and the schedules offered are not especially attractive. A representative schedule stipulates a $12 to $14 treatment charge per ton and payment on New York quotation of 95 per cent of the silver content. With silver selling at 70 cents an ounce the marketing cost per ton on a 300-ounce concentrate would be as follows:

Silver loss 5 per cent (15 ounces at $0.70)	$10.50
Treatment	14.00
Freight	11.32
Representation at the smelter	.50
Bagging and miscellaneous	2.00
Total marketing value for one ton of concentrates	$38.32

This high marketing charge has led to much investigation on part of the companies to devise suitable means for treating their concentrates locally. Cyanidation, desulphurization followed by cyanidation and oxidizing roasting followed by cyanidation of the roasted product gave no promises of economical results. A chloridizing roast followed by leaching, either with cyanide or an acid-brine solution has given the most satisfactory results. The Buffalo Mines is now treating 5 to 6 tons of flotation concentrates daily by this method, and claim a 95 per cent to 98 per cent extraction of the silver values. At this mill the chloridized product is first leached with an acid-leach to extract the base metals and then by a cyanide leach to recover the silver chloride.

Flotation has been adopted very rapidly throughout the district and to date only 790 tons per day of current tailings are not being treated by flotation. There are approximately 2,500,000 tons of impounded tailing in the district averaging 4 to 6 ounces of silver per ton that can be recovered by flotation at a substantial profit. As the ores of the district become lower in value flotation will of necessity become increasingly more important due to the cheapness of the process.

Gold and Silver

Flotation Tests on a Transvaal Gold Ore. F. Wartenweiler, in the Journal of the Chemical, Metallurgical and Mining Society of South Africa, November, 1916, pp. 87 to 90, gives a very interesting comparison of different treatments of a gold ore from the Transvaal. The best extraction was obtained by flotation.

The ore treated was an arsenopyritic gold ore. Grinding this ore to 150 mesh and cyaniding gave a maximum extraction of 45 per cent. By preliminary treatment of the ore with sodium carbonate or sodium hydrate, this recovery may be increased from 3 to 5 per cent. Recovery by amalgamation was so low as to be negligible. Sweet roasting followed by cyaniding gave the following results: The ore was crushed through 20 mesh, and contained 14 dwt. of gold. After roasting, the ore contained 95 per cent of the original gold, the loss being due to volatilization. The gold content of the ore ready for cyanidation was 13.75 dwt., of which 11.95 dwt. were extracted. The balance of gold was in the residue left after treatment with cyanide. The extraction amounted to 86.9 per cent. The net extraction, therefore, amounted to 86.9 per cent of 95 per cent, or 82.5 per cent. The low extraction, combined with high operating costs due to local conditions, would make the roasting operation prohibitive. Trials with gravity concentration and cyanidation gave a total extraction of 70 per cent.

Flotation tests with various oils, and in neutral, alkaline and acid circuits, were carried on, using 500-gm. samples. The coarse sulphide, which was only a small amount of the total, was recovered by panning, and added to the flotation concentrates.

The ore was ground in water to 90 mesh. It was kept submerged so as to prevent serious oxidation. It was pulped in water in a ratio of 5 to 1 with wood creosote and paraffine oil. Lime in solution was added until the alkalinity was 0.005 per cent CaO. The froth produced during the operation was withdrawn continually. After 15 minutes the dark, persistent froth of fine mineral floccules gradually changed to a froth of lighter

color, showing that gangue was being floated. At this stage the machine was stopped and the tailings discharged, in order to study the products. In general, the skimming of the froth was continued until no more mineral matter could be observed. This procedure naturally contaminated the concentrates, necessitating a further cleaning of the product, which was done by passing the initial concentrates through the machine a second time. The products of the second treatment were concentrates and middlings; in practice, the latter would usually be returned to the head of the roughing machine.

The following table will prove of interest, and needs no further explanation:

Product	Per Cent Weight	Assay, Dwt. per Ton	Value per Ton Original Ore, Dwt.	Per Cent of Total Gold Value
Concentrate..	14.7	67.0	9 85	71.1
Middling	12.5	8.7	1 09	7 9
Tail	72.8	4.0	2 91	21 0
	100 0		13 85	100 0

The middlings and tailings were treated by direct cyanidation with air agitation. The concentrate was roasted, then amalgamated and cyanided, the results obtained being illustrated in the following table:

Product and Assay	Treatment	Assay of Residue, Dwt	Extraction, Per Cent	Extraction of Total Value of Ore
Roasted concentrate 30.2 dwt.	Amalgamation and Cyaniding	6 9	94 3	65 0
Middling, 8.7 dwt...	Cyaniding	1.7	80 4	6 1
Tail, 4.0 dwt.....	Cyaniding	1.0	75.0	15.7
Total				87.1

The calculated value of the total residue was 1.78 dwt.

As earlier results with raw sulphide ore gave negative results with cyanidation, the concentrated material was not treated in the raw state. There was practically no premature precipitation of gold by residual carbon from flotation oil ignited during roasting. This matter was determined by treatment of the cyanide residue with sodium sulphide.

The most striking feature of the tests made is the comparative ease with which the gold is dissolved from the middlings and tailings. This emphasizes the extent to which the refractory material is transferred to the concentrates. In practice, it is advisable to assume a 5 per cent loss of gold, due to volatilization during roasting. This loss is 5 per cent of 71.1 per cent, or 3.55 per cent of the original ore. The total extraction is, therefore, 87.1 per cent of 96.45 per cent, or 84.05 per cent.

Copper, Lead and Zinc

Ore Treatment at the Falcon Mine, Rhodesia, South Africa. An article in the *South African Mining Journal*, Dec. 30, 1916, p. 421, by H. R. ADAM, gives a lengthy description of the metallurgical practice at this mine, which is situated at Umvuma, about 160 miles from Bulawayo. The most convenient method of illustrating the practice is by means of flow sheets, but before passing to these it may prove of interest to know that this mine has operated for the past two years, the monthly output being approximately 600,000 lb. of copper, 3000 oz. of gold, and 6000 oz. of silver; 18,000 to 20,000 tons of ore are treated per month, of which 14,000 to 15,000 tons are sulphides and the rest oxides. The sulphide ores contain 2.5 per cent copper as chalcopyrite and 5

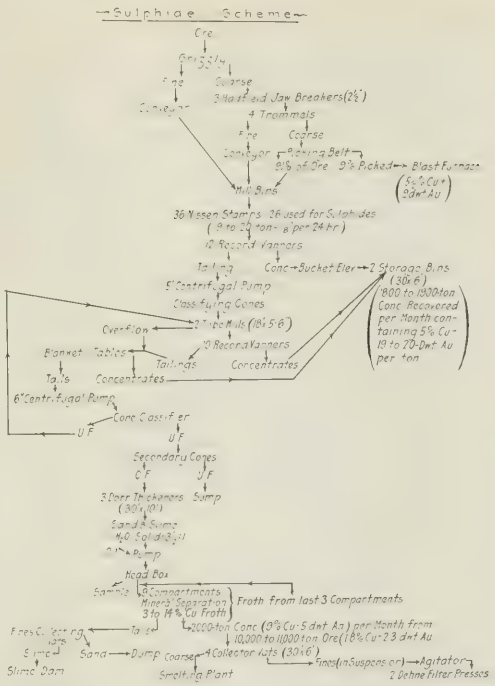

FIG. 4—FLOW SHEET OF MILL OPERATING ON SULPHIDES, FALCON MINE, RHODESIA, SOUTH AFRICA

to 6 dwt. of gold per ton. The chalcopyrite is associated with iron pyrite and pyrrhotite. The oxidized ore runs 0.3 per cent copper and 4 dwt. gold per ton.

Figs. 4, 5 and 6 illustrate the various operations at the mill and at the smelter, and require no further explanation:

It is of further interest to know that the mill concentration plant recovers 60 per cent of the gold and 20 per cent of the copper, while the flotation plant recovers 20 per cent of the gold and 70 per cent of the

copper. This gives a total extraction of 80 per cent of the gold and 90 per cent of the copper. Also it might be especially noted that little or no flotation concentrates are sintered, but are directly delivered to the blast furnaces.

Recent Metallurgical and Chemical Patents

Caustic Soda

Purification of Caustic Soda.—A process for the electrolytic purification of caustic soda is patented by HERMAN B. KIPPER of Solvay, N. Y. The process is applicable to the different processes for the manufacture of caustic soda, such as the lime-soda and the electrolytic process. In these processes the dilute caustic first produced is evaporated in vacuum pans and later in open evaporating vessels. During the process of causticization and of evaporation in the vacuum pans and in the open or cast-iron pots, small amounts of metals are dissolved, which must subsequently be gotten rid of as far as possible. These have usually been removed by settling, the soda being heated up to 500 deg. C. in the cast-iron pots and allowed to cool gradually. According to the present patent, the caustic liquor from the vacuum pans is electrolyzed with nickel anodes with low voltages and a current density of 50 to 150 milliamperes per square inch. One form of apparatus which can be used is shown in Fig. 1, in which 10 designates the purification vessel for the fused caustic soda, it being shown in the form of an open-topped pot which may be composed of iron, the pot being set in a firebox, 11, whereby heat may be applied to raise the temperature of the caustic liquor to the appropriate point. In order to prevent metal from the sides of the pot from entering the caustic liquor, a diaphragm or lining, 12, of fine wire gauze or semi-permeable structure is arranged within the pot and is supported from the inner

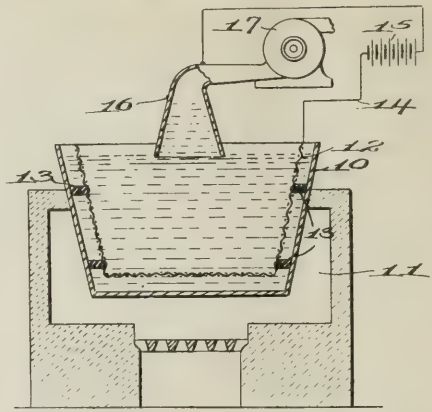

FIG. 1—CAUSTIC SODA PURIFICATION APPARATUS

wall by insulators, 13, the space between the semi-permeable diaphragm or lining and the wall of the pot being filled with powdered limestone. The semi-permeable diaphragm or lining is preferably composed of nickel gauze, and it is insulated from the pot, 10, and is connected by the wire, 14, to one pole of the battery or source of electric current supply, 15. The anode in this construction is in the form of a cone, 16, composed preferably of sheet nickel, the bottom or larger end of the cone being immersed slightly below the level of the caustic liquor in the pot, and the upper end of the conical anode is connected to a vacuum or exhaust pump, 17, which in the operation of the apparatus serves to maintain a slight vacuum within the anode. In this way the caustic liquor is forced up into the anode, the greater portion of the electrical action takes place within the hollow or conical anode, and all oxygen given off in consequence thereof rises through the liquor contained in the cone and is carried off by the vacuum or exhaust pump. (1,227,453, May 22, 1917.)

Waterproofing

Electrolytic Waterproofing.—Three patents have been issued to ALFRED O. TATE of Montreal, Canada, on methods and apparatus for waterproofing fibrous materials. The first patent (1,228,986) relates to a machine for waterproofing, consisting of one or more pairs of stationary electrodes of relatively great contacting surface area, located face to face with their entire surfaces in electrical contact. The positive electrode of each pair is fixed between the ends of a frame, and the negative electrode is adjustable in a parallel plane. The material may be subjected to different electrolytes by spraying on each side as it passes through the electrodes. The second patent (1,228,987) relates to a method of waterproofing consisting in treating fibrous materials with a saponaceous liquid and aluminium acetate simultaneous with the subjection of the material to the action of an electric current between electrodes, one of which is soluble. The third patent (1,228,988) relates to a machine for carrying out the above mentioned process.

The patents are assigned to the Tate Electrolytic Waterproofing Co., Inc., of New York.

Annealing and Heat Treating of Steel and Melting of Non-Ferrous Metals in the Electric Furnace*

By T. F. Baily

The development of electric furnaces for the heating operations subsequent to the melting and refining of steel has been attended by the usual slow process of any radically new development; and the types now in operation are the result of the gradual elimination of weak and faulty features rather than from skill in original design.

In the early development much higher prices were charged for electric current than is now the common rate, and this, in addition to the fact that central stations themselves did not consider electric furnaces commercially feasible, contributed to their slow introduction commercially. The uncertainty of fuel supply and its greatly increased cost within the last year have materially aided the introduction of electric furnaces, and the central stations have of late also taken an active interest in their introduction.

The incidental advantages of the modern electric furnace are so apparent that even at an equal operating cost for fuel electricity now has the preference, while in some cases, where the net cost of operation with electricity is less than with gas or other fuel, complete installations of magnitude are being made.

While it is not the intention to discuss in detail all of the purposes for which furnaces of the type considered in this paper are adapted, the following are some of the uses to which they have been put:

Annealing steel castings and car axles.

Heat treating steel castings.

Heat treating shells.

Carbonizing.

Annealing aluminium, copper, or brass.

Melting copper, brass, aluminium, or silver.

To these lines will shortly be added:

Soaking pits for steel mills.

Rivet furnaces for structural and bridge shops. Later, when there is a serious demand for them, furnaces for heating drop forgings.

It is the purpose of this paper to deal only with furnaces actually in commercial operation.

*A paper read before the Cleveland Engineering Society.

GENERAL DESCRIPTION

All of the furnaces to be described later are of the so-called resistance type, and have, in the case of rectangular furnaces, two troughs made of carborundum fire sand located one on each side of the furnace, with carbon or graphite electrodes located at each end of each trough. The troughs are filled with a broken carbonaceous material called "resistor material," establishing a connection between the electrodes and completing the electric circuit. The general plan of these furnaces is similar to a closed box of fire brick in the walls of which are two glowers, which may be likened to huge incandescent-lamp filaments. The control of the current, and hence the heat, is effected by varying the voltage impressed at the electrodes, this variation being obtained by means of numerous taps on the secondary of a special transformer supplied with each furnace.

CAR-TYPE ANNEALING FURNACES

The furnace shown in Fig. 1 is a car-type 150-kw. annealing furnace, with the capacity of heating 1000 lb. of steel to a temperature of 1650 deg. F. in one hour, and a current consumption of 300 kw. hours per ton of material heated to that temperature. The door of the furnace is a heavy casting faced with fire brick and backed by a filling of loose kieselguhr held in place by a steel plate.

The car-type furnace shown in Fig. 2 is the same in type, but of 300 kw. capacity, and is located in the same plant as the previously described furnace, and is used for annealing steel castings. The charging door is raised, showing how the fire brick car-platform forms the floor of the furnace. Furnaces of this type are well adapted for handling steel castings, and equally well for heating large or irregularly shaped forgings, or for the annealing of copper and aluminium, to which latter use they have already been put.

CONTINUOUS PUSHER-TYPE FURNACES

When materials are of uniform size, or of such shape and nature that they can be pushed along mechanically, or placed in containers of uniform size, the continuous furnace (shown in Fig. 3) is sometimes preferable to the car-type annealing furnace (shown in Figs. 1 and 2).

Fig. 3 shows a 120-kw. furnace carbonizing rifle receivers in one of the large rifle-making plants in the East. The parts to be carbonized are placed in the

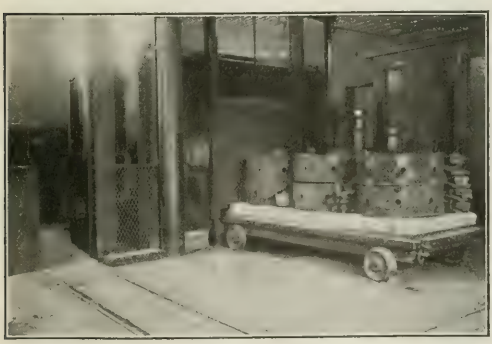

FIG. 1—150 KW. CAR-TYPE ANNEALING FURNACE

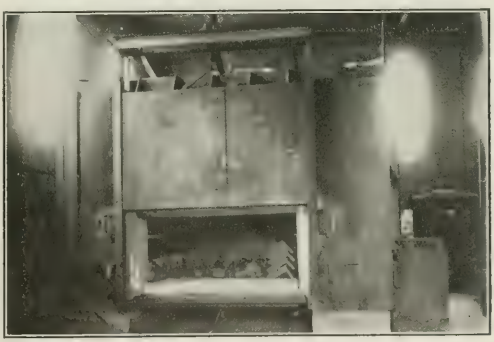

FIG. 2—300 KW. CAR-TYPE ANNEALING FURNACE

usual pots and are pushed through the furnace by means of the pushers, as shown.

Other furnaces of the same general type, but with a different type of pusher, are used for annealing brass and German silver flatware blanks in one of the oldest and best known plants making plated tableware. Two of these 200-kw. units in operation at this plant have an hourly capacity of 1 ton of brass each.

AUTOMATIC HEAT TREATING FURNACES

The heat treatment of steel, as distinguished from the simple annealing operation, consists of heating the metal to above a critical point, quenching at that temperature in some cooling medium, such as water or oil, and subsequently reheating to a temperature under the critical point mentioned.

As materials with specified heat treatment are usually placed in locations where they are to be subjected to considerable strain, more attention has been given to so-called heat-treating operation than to the usual annealing, although both annealing and heat treating are equally important, if dependence is to be placed on the effect that is expected.

For the highest quality of work in heat treating, two furnaces are recommended, each one running with the ruling temperature desired in the material at that particular stage of its treatment, and a quenching bath (or spray, as the case may be) located between the discharge end of the first or heating furnace and the charging end of the second or drawing furnace.

The material is gradually moved forward by a pusher (such as is shown in Fig. 3), removed by manipulators, and quenched in a tank. It is later removed and placed in front of the drawing furnace (as shown in Fig. 3), and later, after having passed through the drawing furnace, discharged and cooled in a specified manner. These particular furnaces, of which there are two sets of two furnaces each already installed in one of our progressive manufacturing plants, are used in the heat treatment of cast-steel drawbar knuckles. Each set has a capacity of 72 tons of steel per day and consumes 900 kw. per set.

These particular furnaces, and a similar set of 600-kw. furnaces for heat treating large high-explosive shells, are automatically controlled by special pyrometers, so that the only hand work required is the placing of material on the charging platform of the first furnace of the set.

Equipment of this type, while expensive in first cost, approaches very closely the highest point of commercial efficiency, as they not only leave no operation to chance but reduce the labor items to a minimum. I believe that it may be said of one of these units that hundreds of thousands of pieces have passed through it without a greater variation in temperature than 10 deg. from the stipulated point.

This type of equipment is adaptable where the material to be heated is of uniform section, or can be placed in suitable metal containers, and where extreme accuracy and minimum labor cost are desired. With such an installation it is possible to produce a uniformity in the product in the plant in line with the tests of the laboratory.

MELTING FURNACES FOR BRASS

The reliability of the type of furnaces described above for annealing and heat-treating work seemed to justify the assumption that with the necessary modifications as to hearth and shape of furnaces they would work equally well on non-ferrous metals. The first furnace for this purpose was installed three years ago for melting silver in one of the plants mentioned previously, where continuous annealing furnaces are used for annealing brass flatware blanks. This furnace was rectangular in shape and provided with a hole in the top and the necessary cover. The metal is melted in crucibles, the furnace being adapted to hold two crucibles of size No. 40. Not only is silver melted, but

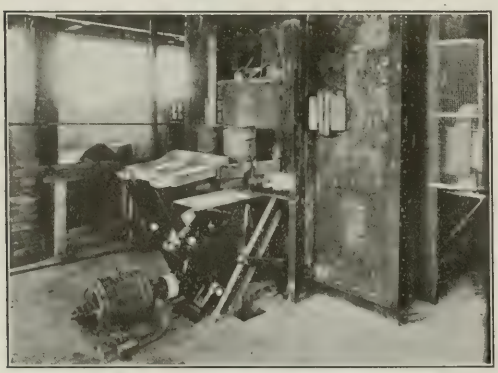

FIG. 3—120KW. CONTINUOUS PUSHER TYPE HEAT TREATING OR CARBONIZING FURNACE

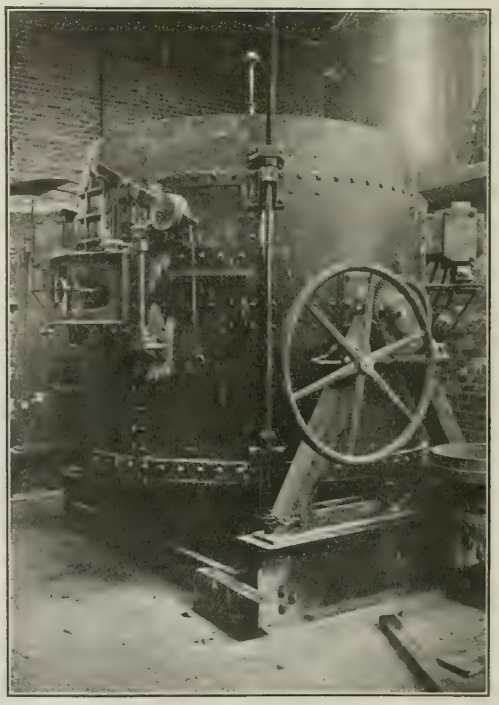

FIG. 4—105 KW. TILTING-HEARTH MELTING FURNACE

scrap copper as well. The ruling temperature of the furnace is 2500 deg. F., very hot metal being required, as the castings are small and the molds are heavy iron chills.

There seems to be no real necessity for the use of a crucible excepting in the melting of precious metals. Their high cost, rapid destruction, and the necessity of handling small quantities of metal when they are used, with attending high labor charge, has led to the adoption of the tilting-hearth furnace shown in Fig. 4. This type of furnace was first used for aluminium and aluminium alloys, and later the same type, with slight modifications in the details, has been used to melt brass.

This furnace, with a normal rating of 105 kw., and a melting capacity of 600 lb. per hour, has melted, and superheated to a suitable pouring temperature, the following materials, with an average current consumption as noted below:

New Red Brass—400-lb. heats in 1 hr. with 90 kwh. or 450 kwh. per ton.
Scrap Yellow Brass—(72 per cent Cu. 28 per cent zinc) 750-lb. heats in 1 hr. 10 min. with 120 kwh. or 320 kwh. per ton.
Scrap Yellow Brass—(70 per cent Cu. 30 per cent zinc) 800-lb. heats in 1 hr. 18 min. with 110 kwh. or 275 kwh. per ton.
Brass Chips and Borings—(70 per cent Cu. 30 per cent zinc) 700-lb. heats in 2 hr. 30 min. with 220 kwh. or 720 kwh. per ton.

Much lower current consumptions have been made on individual heats, but the above are the averages of several heats of each metal.

Of all the electric furnaces of the type described now developed, the tilting-type furnace is the one offering the greatest saving in cost over fuel-fired furnaces of any type, whether oil, gas, or coke fired, since the metal loss is lower, the crucible cost is eliminated entirely, while the labor item is less on account of size and convenience of operation.

The following figures may be safely taken as operating conditions with yellow brass in a shop operating 24 hours per day:

Electricity, 400 kw.-hr. per ton at 1 c	$4.00 per ton
Metal loss, 1 per cent zinc at 10c. per lb.	2.00 per ton
Labor, 1 man per hour per 600 lb., at 40c. per hour	1.20 per ton
Renewals and repairs	1.00 per ton
Total per ton of melt	$8.20

It is believed that the performance of these brass-melting furnaces is such, and the saving over other methods so great, that their introduction will be rapid, even much more so than the annealing and heat-treating furnaces described, which are now accepted without question.

Electric furnaces are not a cure-all for the troubles in the metal industry. They are, however, a much more accurate and precise tool than fuel-fired furnaces, and are the means of eliminating many of the troubles in metal production and manipulation, and will, in the lines for which they are adapted soon come into as general use for heating as electric motors have for power.

The Electric Furnace Co. of America,
Alliance, Ohio.

Porcelain Pyrometer Tubes

For the purpose of protecting thermo-couples at furnace temperatures the tubes made of Marquardt refractory porcelain by the Royal Berlin Porcelain Manufactory have proven very successful, as is shown by the experience of many years. These protection tubes, owing to war conditions, are now not obtainable.

The need of effective protection for the costly platinum and its alloys so extensively used in pyrometry prompted investigation and manufacture in this country. The Ceramic Section of the National Bureau of Standards carried on experiments for the purpose of reproducing, and if possible of improving upon the Marquardt porcelain. The result was a highly refractory product which, though made entirely from American raw materials, was found to be of most excellent quality. The manufacture of this porcelain was taken up by the Stupakoff Laboratories of Pittsburgh, Pa., who successfully overcame the unavoidably attending difficulties, and brought on the market a protection tube under the name "Usalite."

It is claimed by the manufacturers that tubes of this material will readily withstand exposure to temperatures exceeding 1650 deg. C. A highly refractory glaze covers the surface of the outer pyrometer tubes in order to make them impervious to gases of combustion. In strength tests, 5/16 inch unglazed inner tubes; on supports placed 5 inches apart, broke under a centrally applied load of 20 pounds. Outer tubes of standard size 11/16 inch diameter, submitted to the same test broke at 212 pounds.

An 18-in. outer tube, freely suspended at its upper end, broke under impact test by applying a 50 pound weight to its lower end when swinging from an angle of 90 deg. Exposed to a temperature of 1370 deg. C., standard outer Usalite tubes in a horizontal position and unsupported for 6 inches did not bend during six weeks' continuous service.

Usalite tubes, when withdrawn from white hot furnaces and brought into the open air neither broke nor cracked. The smaller diameter unglazed tubes effectively withstood sudden exposure to the highest temperature. A glazed outer tube heated to 1100 deg. C. readily withstood the introduction of cold steel rod of nearly the same diameter as that of the bore of the tube.

Rare metal thermo-couples and resistance thermometers, which are made of platinum and platinum alloys, require considerable protection. These metals, when heated, absorb large quantities of gases and metallic vapors, and when in this state they also readily combine with phosphates and silicates, all of which contribute to causing physical changes and making them unfit for their intended use. For these reasons the insulating tubes, containing the active portions of the pyrometers, are slipped into other (outer) protection tubes with closed ends. These tubes, besides possessing all the properties required of the inner tubes, must remain impermeable to gases at high temperatures.

Impermeability is imparted to porcelains by glazing their surface. The best of such glazes begin to soften at about 1400 deg. C. (about 2550 deg. Fahr), whereafter imperviousness rapidly diminishes. Pure silica and the silica glazes of porcelain tubes at high temperatures devitrify in a reducing atmosphere and combine with alkaline substances. It is therefore recommended to enclose, whenever possible, the outer pyrometer tubes in others which combine mechanical strength with refractoriness and density of structure. These shields, which are commonly known as pyrometer tips, serve as an effective protection for the fragile pyrometer tubes against breakage through mechanical injury and sudden changes of temperatures, beside, serving as effective filters of furnace gases and vapors.

Fundamental Hue Scale for Scientific Color Designation

Dye manufacturers and those who deal in or have much to do with various kinds of dyes will without doubt gladly welcome anything that will tend to increase the accuracy of color designation and nomenclature. They will, therefore, be interested in an extensive series of experiments recently carried on in the Research Laboratory of the Eastman Kodak Company for the purpose of obtaining a fundamental color scale.

There are two ways of analyzing and specifying color, one being the trichromatic method of analysis in terms of the three primary component colors, red, green and blue, and the other the monochromatic method of analysis in terms of the wavelength of the dominant hue or its complementary hue and the per cent white (purity or saturation). The fundamental color scale as determined in the Kodak Research Laboratory is based on the monochromatic method of analysis, and it is the purpose of this article to show how important this method is to any one interested in reliable color nomenclature and describe the method of determining the unit for the color scale.

When light rays from the sun or other luminous object or substance impinge upon the retina of a normal eye, sensations of light are produced, and in such sensations two factors may be distinguished, one being a factor of brightness and the other of color. The sensation of brightness is dependent upon the intensity of the light and that of color upon what may be termed the "quality" of light radiation. Light energy is transmitted in the form of waves of varying wavelength, and the quality of the light radiation, which the eye perceives as color, is dependent upon the length of the waves.

Pure color is produced by homogeneous light—that is, light of equal wavelengths. Usually, however, colored light is made up of a number of different kinds of wavelengths, and the eye cannot recognize the individual component wavelengths, but averages the mixed radiation as a single stimulus which produces a single color sensation. When a color is produced by light of one wavelength which exactly matches the single-color sensation of mixed radiation, the color is called the dominant hue of the mixture. Moreover, the extent to which the light consists of wavelengths of different color varying about that of the dominant hue as an average is called the "saturation" or "purity" of the color, a pure hue being produced by waves of only one length, while less saturated colors consist of waves of varying length. Light such as that coming from the sun, for instance, consists of a variety of wavelengths, the combination of which causes a sensation of white light to be produced. Sunlight can be broken up into its various components by means of a glass prism or diffraction grating, thus providing the various colors of the spectrum.

The sun, of course, is our greatest source of light, and spectral colors obtained from noonday sunlight are accordingly by far the best colors to take as standards in the preparation of a fundamental color scale. The number of gradations of color, or hues as it is more proper to call them, perceptible to the eye in the spectrum depends upon the experience of the observer and the apparatus used, varying from the six so-called dominant hues (red, orange, yellow, green, blue and violet) to 128 distinct hues distinguished by careful observation with the special apparatus used for this purpose.

It can be demonstrated experimentally that with the exception of the purples, any color can be matched by adding white light in the proper proportions to spectral light of some definite hue (monochromatic or pure single-color light), and the saturation or purity of the color is indicated by the extent to which the color departs from the condition of monochromatism. In this way a direct measurement of fundamental properties of a color can be made, the hue being specified by the wavelengths of the monochromatic light used (wavelengths of the dominant hue) and the purity or saturation by the ratio of the intensity of the white light to that of the monochromatic light (per cent white).

In the case of the purples for which there are no spectral colors to represent their hues, some mixture of the color with monochromatic light can be made by which the sensation of white will be produced, the terms of the color specification then being the wavelength of the complementary dominant hue (the hue which when mixed in the proper proportions with the color to be matched produces white) and the per cent of monochromatic light in the mixture (per cent hue).

Now it seems to be apparent that, since wavelengths of radiation is used to express hue, if a hue scale is to be established, the points on the scale should be designated in wavelength units. It has been found, however, that equal wavelength differences do not produce equal color sensation differences throughout the sensation scale under consideration. Hence, the wavelength unit is not suitable for use as a unit in the establishment of a scale of subjective color sensation, since the first requirement of a scale for the measurement of any quantity is that the unit used shall be of a fixed magnitude and of the same value throughout the scale.

The only alternative is to adopt the least perceptible color sensation difference as a unit and assume that this sensation unit is equal at all points in the sensation scale. This unit is called a limen and is the least perceptible difference between two hues in terms of μ (wavelength is usually given in terms of ten-thousandths of a centimeter, the unit being expressed by the Greek letter μ). The question as to whether such a sensation difference unit is equal at all points on any sensation scale has been discussed at great length by philosophers and psychologists; but from a purely physical standpoint, it seems entirely reasonable to make the difference limen equal at all points on a sensation scale by definition and to adopt this least perceptible difference as a sensation unit and to use it for the establishment of color sensation scales.

The problem of establishing a fundamental hue scale then, after finally getting down to the meat of the matter, is to determine for the entire range of visible radiation, going from red to violet, or vice versa, the relation existing between the wavelength unit and the least color sensation difference unit. In the solution of the problem the first step is the determination of precise values in terms of the wavelength units for the average normal eye of the least perceptible hue differences (sensation units) throughout the visible spectrum. The final values, then, must be the result of the

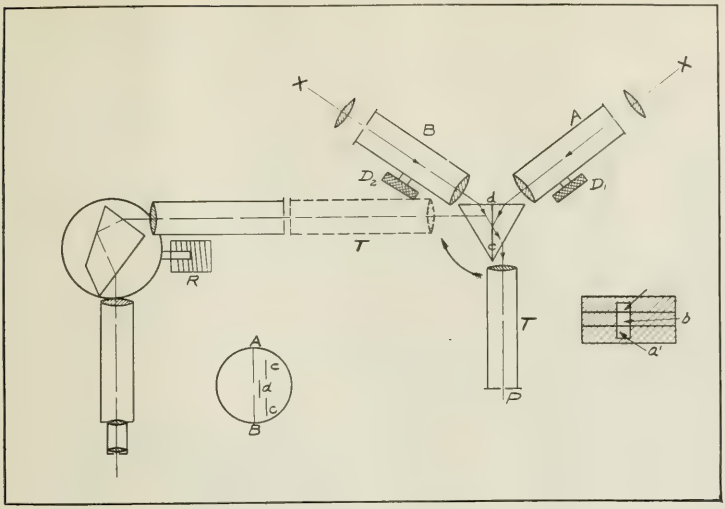

FIG. 1—ARRANGEMENT OF MEASURING APPARATUS

proper summarization of a large amount of data obtained from the study of a large number of different individuals having normal vision.

In the measurement of the difference limen highly refined apparatus is required. Considerable data were obtained in the Kodak Research Laboratory with a Brace Spectrophotometer, which was used in connection with a Hilger spectroscope of the constant deviation type. The arrangement of this apparatus is indicated in the diagram in Fig. 1. A and B represent two collimating systems, the angular positions of which can be adjusted by means of the micrometer screws D_1 and D_2. The prism consists of two 30-deg. elements cemented together along the line ed, thus forming a compound 60-deg. prism. On one of the cemented faces is a narrow silvered strip (about 8 mm. wide) which is parallel to the base of the prism and centrally placed in the vertical direction. By looking through the pinhole ocular P of the telescope T over the object glass of which is placed a diaphragm with a rectangular opening, a field as shown at the right in Fig. 1 is seen. The portions of the field aa′ appear to be illuminated by monochromatic light from the system B and the area b by light from the system A.

The entire system is mounted on a table in such a manner as to bring the telescope T into alignment with the collimating system of the Hilger spectroscope. By looking through the eyepiece of the Hilger instrument and by bringing the lines in the field on to the cross line of the eyepiece, the wavelength of the light entering the slit, from the fields aa′ and b of the spectrophotometer can be accurately measured. The field that can be seen is shown in Fig. 1. A B is the reference line of the eyepiece, cc′ the lines due to the light coming from the portions aa′ of the spectrophotometric field and d is the line due to that from the portion b. The wavelength of each can be precisely measured by bringing them one after the other into coincidence with the reference line A B, reading the value directly from the calibrated wavelength drum R.

With the apparatus shown the difference in the wavelength of the light illuminating two fields, which appeared just perceptibly different in hue, was obtained. Since the desired scale is that of pure hue, fields illuminated by light as nearly monochromatic as possible must be used in such work, and it is also very important that the intensity of the light be easily controllable, for in making a judgment of equality or difference hue, it is necessary to maintain an intensity balance between the fields in order that the judgment of hue may not be influenced or confused by the existence of an intensity difference.

In Fig. 2 are shown two curves plotted from data obtained in the Kodak Research Laboratory. The abscissa or horizontal values are given in one-thousandths of μ (designated as $\mu\ \mu$), the violet hues being in the

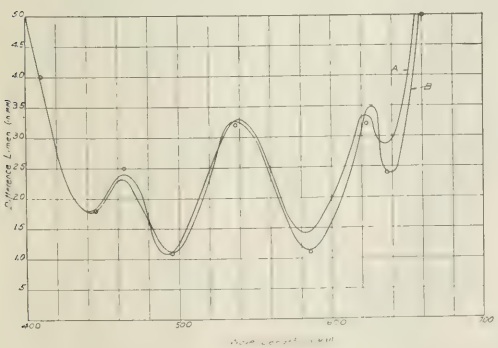

FIG. 2—TWO TEST CURVES

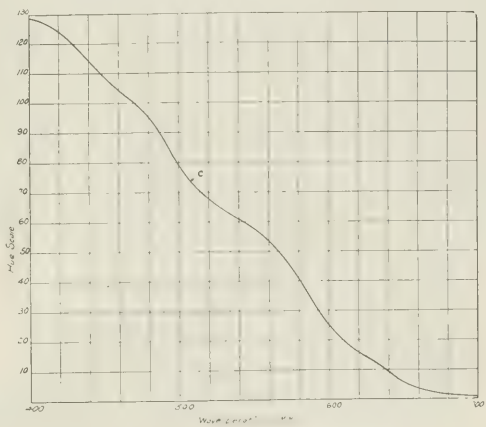

FIG. 3—HUE-SCALE READING CURVE

neighborhood of 400 μ μ; blue, 480 μ μ; green, 520 μ μ; yellow, 589 μ μ; orange, 600 μ μ; red, 660 μ μ. The ordinate values are difference limen or smallest perceptible hue differences in terms of μ μ in various parts of the spectrum. These curves agree very well with curves plotted by other observers and they prove the statement already made, that equal wavelength differences do not produce equal color sensation differences.

In Fig. 3 is shown a hue-scale reading curve, the data being obtained by a method that involved the use of the least perceptible hue difference as the *actual unit* of measurement. Starting at a given point the entire spectrum was measured off step by step with the difference limen as the unit of length. This method gives the total number of just perceptibly different hues present in the spectrum and the distance apart of these equal sensation steps in terms of the wavelength unit. The number of distinct hues found in the Kodak Research Laboratory in a very careful set of readings was 128 between 400 μ μ (violet) and 700 μ μ (red). By plotting the consecutive wavelength readings as abscissae against equal ordinate increments—these readings correspond to equal sensation steps—the scale-reading curve as shown was obtained directly.

How great the value of a fundamental hue-scale with the least perceptible hue differences as a unit may be can now be readily ascertained from a close study of the scale-reading curve shown in Fig. 3. Let one imagine, for instance, that the hue-scale shown has been definitely adopted and standardized, then it is easy enough to state the position of the dominant hue on the scale and to complete the specification by giving the degree of purity or saturation of the color.

A New Carbon Electrode Factory

Work has already been started on the first unit of a new factory that will form an immense addition to the present large plant of the Speer Carbon Company at St. Marys, Pennsylvania, and which, when entirely completed, will involve the expenditure of approximately $500,000.00 for additional land, buildings, machinery, equipment and general improvements.

The new factory will occupy the plot of ground east of the present plant, and it is expected that a number of similar units will be erected as labor and materials are available. The company has been acquiring additional land immediately adjoining its present large holdings.

The first building, which will be devoted exclusively to the manufacture of the larger sized carbon electrodes for electric furnaces, will be 100 x 168 ft. in size and constructed entirely of brick, concrete and steel. Glass sidewalls will also be employed, thus permitting a volume of daylight throughout the entire structure. The contract for the erection of the building has been awarded to the W. L. Goeltz Company of New York City. The erection of the furnaces and the installation of the machines and equipment will consume several weeks, but it is expected that the entire plant will be in full operation by September, 1917.

The Speer Carbon Company has for several years past manufactured carbon electrodes in the smaller dimensions, the maximum sizes including 4 in. square and 6 in. in diameter. The new factory will be equipped to turn out both round and square electrodes in all sizes from 6 to 24 in. in diameter.

The demand for carbon electrodes is daily increasing, the condition being caused by the enormous demand for tungsten steel and other products which, in turn, necessitated the installation of large numbers of electric furnaces throughout the entire country. The requirements of the Government have also influenced the Speer Carbon Company very largely in the erection of a new plant and once it is in full operation the carbon electrode shortage will be greatly lessened.

Tripod Stand for Portable Galvanometers

The tripod stand shown in the accompanying photograph, Fig. 1, is a product of the Stupakoff Laboratories, of Pittsburgh, Pa. It was designed to do away

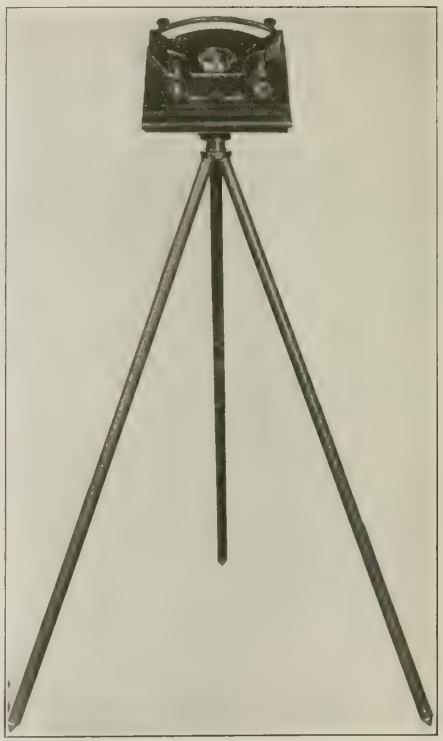

FIG. 1—TRIPOD FOR PORTABLE GALVANOMETERS

with the inconvenience of finding a suitable resting place for portable galvanometers. The stand is designed to fit all of the company's instruments.

Manganese Mining Active.—Secretary Lane recently made the following statement on manganese: "The manganese situation is most encouraging and the U. S. Geological Survey estimate for 1916 is 80,000 tons of the high grade ore. This, however, is less than 20 per cent of the present large demand of the steel industry. Production of low-grade ore is also increasing.

Personal

Mr. **L. W. Bahney** has left the Sheffield Scientific School of Yale University to take a position as metallurgical engineer with the Scovill Manufacturing Co., Waterbury, Conn.

Prof. **H. K. Benson,** instructor in industrial chemistry at the University of Washington, Seattle, and director of the Bureau of Industrial Research, will spend his summer vacation at the plant of the American Nitrogen Products Compnay at La Grande, Wash., where he will conduct research work relating to the manufacture of nitrogen products from the air by use of electricity. Prof. Benson will return to his school work in the fall. He is an associate member of the U. S. Naval Advisory Board.

Mr. **Arthur F. Braid** has assumed the duties of metallurgical engineer in charge of metal sales for the Goldschmidt Thermit Co. of Jersey City, N. J. He succeeds DeC. Brown, who has joined the Officers' Reserve Corps at Plattsburg.

Prof. **G. H. Clevenger** of Leland Stanford, Jr., University was recently in New York, having just returned from the Cobalt District in Ontario, where he has been making some investigations for the Bureau of Mines.

Mr. **S. C. Dickinson,** formerly with the United States Bureau of Mines, assumed the duties of safety engineer with Arizona State Bureau of Mines on July 1.

Mr. **B. H. Dosenbach,** flotation engineer for the Butte, Superior, was in Denver on business.

Mr. **S. L. Nicholson,** sales manager of the Westinghouse Electric & Mfg. Co. since 1909, has been made assistant to the vice-president of the company, with headquarters at East Pittsburgh. Mr. **H. D. Shute,** whose election as vice-president of the W. E. & M. Co., was recently announced, will have executive charge of the company's commercial organization, both domestic and export, succeeding vice-president L. A. Osborne, whose headquarters have been transferred to New York.

Mr. **Burr A. Robinson** has resigned as assistant secretary of the American Institute of Mining Engineers to go into industrial work, and Prof. **G. A. Roush** of Lehigh University has taken up his work as managing editor of the Institute's Monthly Bulletin.

At the commencement of the Colorado School of Mines the honorary degree of E.M. was given to **Walter G. Swart** and **H. W. Hardinge.**

Mr. **O. H. Wharton** is the new president of the Crucible Steel Co. of America. He is a native of Easton, Pa., and was for many years general sales manager of the company, following which he was assistant to president C. C. Ramsey.

Mr. **Kwong Wu,** mining engineer for the Ministry of War of China, spent several weeks at Nederland, Col., inspecting the various tungsten mills of the district.

CURRENT MARKET REPORTS

The Iron and Steel Market

There is little to be said about the iron and steel market. It appears to be in the throes of a transition from its recent runaway condition to a state of being regulated by Government authority. The regulation of iron and steel prices, which an amendment to the food bill in the Senate places in the power of the President, is likely to remain in the bill for its final passage, and the President is likely to exercise the authority when granted, unless the manufacturers are able to devise a system under which the trade can operate to the satisfaction of all parties concerned. This may be undertaken, though the experience of the coal operators does not encourage them to undertake to do anything that will satisfy more than one or two Cabinet officers at a time. It will be recalled that the agreement of the coal operators was made with the Secretary of the Interior, who was well pleased, and as soon as the secretaries of the War and Navy departments read about it in the newspapers they hastened to "repudiate" it, though they afterwards reconsidered their dictum.

The steel market has grown narrower and narrower, as to the tonnage turnover. The mills have withdrawn more and more from the market, while buyers have become more and more averse to making engagemenets for far forward deliveries. The business done has been confined more and more to early deliveries, with a very few months. For such deliveries there are very few buyers and very few sellers, hence an extremely narrow market. The buying pressure has preponderated, however, and the market prices disclosed by the few transactions made have shown an almost constant advancing tendency. As the prices are, on an average, about double the prices at which the bulk of the shipments are now being made, on old contracts, they are in large manner fictitious, though strictly speaking they represent the market since there is no other market to quote.

PIG IRON

The pig iron market is much broader than the steel market, in that there are transactions involving the delivery period for which the majority of the furnaces are in position to sell. Sales for the first half of 1918 involve a much larger tonnage than sales for the remainder of this year, and occasionally there has even been a little business done for the latter half of 1918. Prices show but little divergence for the different deliveries, though in most cases there is a difference of from $1 to $3 a ton. All districts except Alabama and Tennessee now show a market price of $50 or higher f.o.b. furnace, approximately three times the price at which a great deal of iron was sold for delivery during the first half of the current year.

The pig iron market, however, has grown decidedly quieter in the past fortnight. The volume of transactions has greatly decreased, and price advances seem almost to have ceased. Indeed, there are some indications that southern iron is scarcely as firm as a fortnight ago.

GOVERNMENT STEEL

The war requirements in steel are multiplying, but there is little concrete information as to tonnages, and nothing like a close estimate can be made as to the prospective total. It may be remarked however, that at the time war was declared estimates of war requirements ranged from 5 to 20 per cent of the output, while a month ago the more enterprising were disposed to predict 40 per cent, and at present there are many who

believe the total requirements will exceed 50 per cent. The change in view is due to the fact that the Government finds it necessary to engage in more undertakings than was expected. If steel can be secured and fabricated there are prospects that large numbers of cars and locomotives will be bought, both for domestic use and for export, and it may be found desirable to foster the manufacture of agricultural implements and engage in other enterprises. These extra items would represent peace steel taken in change by the Government for war purposes.

Non-Ferrous Metal Market

Monday, July 9.—The markets are in a slightly easier position, with the exception of tin, which is practically unchanged. Copper has declined slightly, lead is lower in the outside market and antimony has declined considerably. The situation in spelter is unchanged. Silver remains high and firm.

Copper.—The Government purchased on June 29, 60,000,000 lb. of copper at 25 cents. The price, however, is understood to be tentative and subject to investigation by the Federal Trade Commission of the cost of production. The average monthly exports so far this year have been over 100,000,000 lb., or more than twice last year's amount. Since the first of July the copper market has been quiet pending Government action on copper prices. Electrolytic has declined from 32.25 on June 27 to 31.25 on July 6. Lake has remained practically stationary at 31 cents.

Tin.—Tin has been firm with a slightly upward tendency. Spot Straits is held at 62.00 to 62.50 cents. August delivery, 61.00, September 59.50-60, October 58.50 and November 57.50. June deliveries are estimated by the American Metal Market to be about 5000 tons. There has been a noticeable increase in the supply of tin other than Straits.

Lead.—The feature of the lead market has been the lower outside market. Lead sold up to 12.00 cents in this market a short time ago, but is now down to 11.25. The Trust price remains stationary at 11.00 cents.

Spelter.—The Government purchased 11,000 tons of high grade spelter the last week in June, for delivery over the next 10 months. The price was 13.50. This purchase did not have any noticeable effect on the market, and consumers are still holding off. The demand for spelter is very poor and the market continues dull. Prompt spelter is quoted at 9 to 9.25 cents.

Other Metals.—Antimony has declined from 18.75 on June 27 to 16.75 on July 6. Consumers are apparently well supplied and the good supply made an easy market. Antimony is stronger in China, owing to the disturbed conditions, but developments there have not affected the market here as yet. Aluminium is lower at 56 to 58 cents for No. 1 Virgin metal. Magnesium is $2.00 to $2.50 for prompt shipment. Quicksilver is $85.00 per flask. Platinum is unchanged at $105.00 per oz. Silver is 78⅜. The situation in tungsten concentrates is very acute and concentrates are hard to obtain. They are quoted at $20-$22 per unit.

Chemical Market

Generally speaking, there has been little excitement in any division during the interval and prices have in the large majority of cases moved within rather narrow margins. Buying has been more or less on a rather limited scale due in part to the growing difficulty of exporting merchandise when there is a foreign market and also to the fact that in the absence of further definite advices from the government regarding those materials that are essential in the furtherance of defensive and offensive measures, buyers, and in not a few instances sellers, are withdrawing from the market as far as possible for the time being. On the other hand, many chemicals, such as caustic soda, aqua ammonia, sulphate of ammonia, etc., which are in relatively light supply, have been subject to a particularly heavy demand and prices have accordingly registered material advances.

Benzol.—On the whole there has been little activity and in many instances manufacturers have accumulated moderately large quantities, which have been held with more or less steadiness pending the government's requirements regarding purchases of picric acid. The question is now whether or not the government's requirements for T. N. T. will be taken care of. In the event that the T. N. T. cannot be supplied in sufficient quantities, it is almost certain that orders for picric will be forthcoming. Large producers have established a minimum of 55c. for nearby deliveries, and while this price is generally adhered to some concessions are being made by those who are less confident of the future.

Among the benzol derivatives *Aniline Oil* has continued to play a fairly important role, and the market has held with some steadiness, due more to the relatively high cost of production than to any unusual demand; the market for *salts* has been fairly well maintained and those concessions that were made were due mostly to inferior grades. *Paranitraniline* has been quiet and production appears to be somewhat heavier than immediate needs. On contract, prices are shaded materially, although the spot market is not subject to great weakening. *Dimethylaniline* has kept up only because of the increasing cost of production, as export business and domestic orders have been light. *Monocolor benzol* is being produced on a wider scale and important makers have reduced both spot and contract prices.

Toluol.—Among all the coal tars this has played the most conspicuous part, due to its importance in the manufacture of explosives as well as in the production of much wanted derivatives. At least four large makers are now under contract for their entire production of T. N. T. for the government and the price paid is based on toluol at $1.50. For those who have not their own by-product recovery plants the government has been buying toluol, but the attitude of the officials at Washington has changed, and it is stated that T. N. T. makers will hereafter have to supply their own toluol. Small lots of *toluol* are being sold steadily for dye making and as a rule at moderately lower prices than those that prevailed two weeks ago. *Paratoluidine* and *paranitro toluol* have been subject to pressing demand and the output up to this time is hardly taking care of the needs of consumers. *Toluidine* also has been in good request, and with limited supplies the market has been maintained with considerable strength.

Phenol.—Apart from the running contract business, routine demand from dyestuffs and intermediate makers, occasional orders from abroad, especially Japan, there has been little activity and prices are not held with any particular strength. Production continues large and is capable of meeting the needs from all directions. *Dinitro phenol* is being made on a larger scale and compe-

tition has induced in some cases a lowering of prices. Contracts are to be had now at fairly large concessions from recent levels. *Para amido phenol* and *paraphenylediamine* are sought after with comparative steadiness, and some makers have advanced their prices. There is no open market for *picric acid* and until the government expresses a desire for supplies the market will be nominal, with little demand and a small production.

Naphthaline.—The absence of wide inquiry has brought prices down fractionally and there is no really important business in progress either for the flakes or balls. Practically all the derivatives of this base are in light demand and prices have declined, some slightly and others materially. The competition for *alpha-naphthylamin* business has induced lower prices, although the output is as a rule being taken up steadily.

H-acid (Amido naphthol di sulphonic acid).—Again this intermediate is brought into prominence by the knowledge that one other maker who has been working on the product for a long time has finally been able to offer material quantities for immediate delivery and regular supply.

Bleaching Powder has been on the down grade for some time, and both domestic and export containers of all kinds are now available at lower prices than have been in existence for a long time. The facts that paper mills are not busy, that some are using their own liquid bleach, that in summer bleach loses its chlorine strength rapidly, and that export business is negligible, have all been factors in bringing about the weak condition.

Potash Compounds.—Muriate has been subject to but light demand, and prices for the syndicate's goods have been reduced materially. A factor has been the importation of more desirable Japanese goods as well as the offerings of domestic kelp potash. *Bichromate of potash* has been inactive, although prices have not fluctuated except within narrow margins. *Caustic potash.* All grades not being under noteworthy buying pressure have eased off somewhat, as manufacturers' supplies have increased. *Carbonate of potash,* both hydrated and calcined, is in light supply, and the most recent business that passed has been at comparatively high levels. *Potash alum.*—Lump prices have been subject to upward revision, due to the demand and higher cost of production.

Soda Compounds.—*Caustic soda* has taken by far the most important position as far as active trading is concerned. The market is in a tight position and while there are spot goods here in New York they are held in strong speculative hands and the market is being forced up to high levels. The interest now centers in 1918 contracts to an extent equal to the spot demand and in fact all positions from July delivery to the end of 1918 are subject to weighty demand.

Soda Ash.—This market has not followed, as usual, the fluctuations of the caustic market, and prices have remained at comparatively low levels. The absence of heavy demand, of course, is responsible. The fact that steamship companies will not accept ash packed in bags, and are now even stipulating that it must be packed in nardwood casks, has an important bearing on the position, as, on account of the tight cooperage situation, a very large proportion of the output is packed in bags.

Bichromate of soda has been moving with moderate briskness, and some makers are still trying to bull the market now that one maker is out and the productions of two more have been sold up for the next several months. *Silicate of soda* is subject to wide demand and manufacturers are still unable to deliver for some time to come. *Nitrate of soda* has advanced considerably under heavy buying, both for domestic needs and export. *Nitrite of soda* is now being made here in somewhat larger quantities, but as yet only the two large producers are delivering, and their product is sold ahead for some months. The demand is wide and prices are high.

Ammonia Compounds.—*Sulphate* production in this country is not taking care of fertilizer needs here, and some of the numerous export orders are going unfilled. *Aqua ammonia* and *nitrate of ammonia* are in such demand that prices, especially of the former, have increased perceptibly every few days and any supplies offered at moderate prices are immediately picked up.

Acids.—*Acetic,* especially 80 per cent. redistilled and pure and the glacial, have been offered here during the interval in quantities that have not been available for many months; the result was that the high prices sagged considerably, but the market is strengthening again to near the former levels, as the goods are being sold to go into consumption. *Muriatic acid* is offered at fractionally lower prices and while there is a tendency to maintain certain levels desirable business is given consideration. *Nitric acid,* on account of the higher cost of the nitrate of soda, has been advanced and makers are now endeavoring to get 12c. per unit for all grades; the demand, however, at these levels is not forthcoming and the market is quiet. *Sulphuric acid* (*brimstone*) has been shaded in a few instances when good orders come into the market, despite the fact that the higher cost and uncertainty of securing brimstone has produced a fundamentally stronger tone. This is more in evidence on future positions and most makes will not take business further ahead than August.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, JULY 6, 1917

Acetic anhydride	lb.	1 70	—	1.90
Acetone, drums	lb.	.29		.29½
Acid, acetic, 28 per cent	lb.	.05		.05½
Acetic, 56 per cent	lb.	.10		.11
Acetic, glacial, 99½ per cent., carboys	lb.	.34	—	.35
Boric, crystals	lb.	.13	—	.13½
Citric, crystals	lb.	.72½	—	.73
Hydrochloric, commercial, 18 deg	lb.	.01⅛	—	.01½
Hydrochloric, 20 deg	lb.	.01½		.01¾
Hydrochloric, C. P., conc., 22 deg	lb.	.01¾	—	.01¾
Hydrofluoric, 30 per cent., in 1 barrels	lb.	.04¾	—	.05
Lactic, 44 per cent	lb.	.11	—	.12
Lactic, 22 per cent	lb.	.04½	—	.05
Nitric, 36 deg	lb.	.07¼	—	.07½
Nitric, 42 deg	lb.	.08	—	.08¼
Oxalic, crystals	lb.	.15	—	.16
Phosphoric, 85 per cent	lb.	.33		.37
Picric	lb.	.70		.75
Pyrogallic, resublimed	lb.	3 50	—	4 00

New Companies

The Advance Chemical Company, Wilmington, Del., has been incorporated with capital of $1,000,000 to manufacture chemicals, etc. The incorporators are: M. L. Rogers, L. A. Irwin and Harry W. Davis, all of Wilmington.

American Foundry Company, Inc., Elizabeth, N. J., has been incorporated with a capital of $125,000 to conduct a foundry business. Incorporators are Mary T. McCarthey, Rahway; Morris Jegger, Otto Froebel, Elizabeth.

The Beaver Chemical Company, Inc., New York, has filed articles of incorporation with capital of $10,000 to manufacture chemicals, etc. The incorporators are H. and B. Lichtenberg and S. Fillin, all of New York.

The Brettler Sheet Metal Works, New York, has been incorporated with a capital of $10,000 to manufacture iron floor plates. B. Brettler, the principal incorporator, operates a metal working plant at 227 East 47th Street. A. and M. Brettler are the other incorporators.

Charleston Alloy Steel Company, Belle, W. Va., has been incorporated with a capital of $500,000 to manufacture iron, steel, manganese, coke, copper, lumber and other minerals. The incorporators are J. M. Payne, Berkeley Minor, Jr., J. F. Bouchelle, E. A. McCoy and G. F. Brennan, all of Charleston.

The Clarke-Kessler Company, Wickliffe, Ohio, has been incorporated with a capital of $250,000. Incorporators are H. W. Kessler, C. R. Kessler, G. W. Clarke, Edgar J. Tyler and J. M. Shallenberger.

The Clement Synthetic Gas & Chemical Co., Inc., New York City, N. Y., has been incorporated with a capital of $5,000 to manufacture chemical compounds, dyestuffs, airplanes, automobiles. Incorporators are L. Clement, R. T. Grogan, H. Boes, 119 E. 88th St.

Wm. M. Crelin & Co., Newark, N. J. has been incorporated with a capital of $100,000 to manufacture chemicals, oils, greases, etc.

The Crescent Rubber Corporation, Chicago, has been incorporated under Delaware laws and capital of $1,500,000 to manufacture rubber and rubber products. The incorporators are: F. R. Kelley, Elgin, Ill.; George H. Gilberda, and R. S. Hanford, of Chicago.

Cuban Air Reduction Corporation, New York City, N. Y., has been incorporated with a capital of $267,500 to manufacture oxygen, nitrogen and other constituents of oil. Incorporators are F. A. Huehk, J. B. Kilburn, C. F. Wicker, 60 Broadway.

The Cumberland Petroleum & Refining Company has been incorporated in Delaware with a capital of $1,000,000 to produce and market oil and petroleum. Incorporators are John F. Sever, Kansas City, Mo.; R. C. Clapp, U. S. Barr, Wichita, Kans.

The Delion Tire & Rubber Company, Trenton, N. J., has been incorporated under Delaware laws with capital of $3,500,000 to manufacture rubber goods of different kinds. The company has a plant on East State Street, and is now building two 1-story additions, about 50 x 100 ft. and 25 x 65 ft.

The Delta Iron & Furnace Company, Chicago, has been incorporated with Delaware charter and capital of $5,000,000 to operate iron properties. Richard H. Holden, John A. Massen and DeGroot Van Baekeman, all of Chicago, are the incorporators.

Dixie Chemical Corporation, Petersburg, Va., has been incorporated with a capital of $180,000. Incorporators are C. W. Stratford, president, New York; W. J. Sommers secretary-treasurer, Petersburg.

The Dural Rubber Company, Trenton, N. J., has been incorporated with a capital of $200,000 to manufacture rubber and other specialties. The company has acquired a site at Flemington, N. J., and plans for the immediate establishment of a plant for the manufacture of automobile tires, rubber goods for aircraft and aeroplane parts. Edgar H. Wilson, Trenton, is president. Other incorporators of the company are Newton A. K. Bugbee, James C. Tattersall, H. M. Voorhees and John G. Connor. Local offices have been established at Room 711 Broad Street Bank Building.

Durex Aniline Works, Inc., New York City, N. Y., has been incorporated with a capital of $10,000 to manufacture dyes, paints and chemicals. Incorporators are S. E. Baer, H. M. and M. Toch, 329 West 86th Street.

Durham Paper & Pulp Company, Phillipsburg, N. J., has been incorporated with a capital of $125,000 to manufacture paper, paper materials, pulp, etc.

Edgewood Glass Company, Hamilton, Ill., has been incorporated with a capital of $125,000. Incorporators are W. A. Baybourne, E. F. Phillips, William Sinton, W. S. Phillips, Jacob Scheuton, F. A. French.

The Empire Smelting & Refining Company of Chicago have been granted a permit to do business in Texas, with a capital stock of $100,000, with headquarters at San Antonio and El Paso.

Freeport Chemical Company, Freeport, Tex., has been incorporated with a capital of $100,000 to manufacture sulphur products. Incorporators are Christian B. Sanbriskie, New York City; Christian De Guigno, Jr., Hillsborough, Cal.; George P. Howard and William A. Vinson of Houston.

Gillillan Bros. Smelting & Refining Co., Los Angeles, Cal., has been incorporated with a capital of $100,000. Incorporators are S. W. Gillilan, C. F. Gillilan, L. G. Brown, A. W. Klusmann and G. L. Alspach.

Greenback Mining & Smelting Company, Wilmington, Del., has been incorporated with a capital of $250,000 to conduct a general mining business.

C. H. Hall, Plainfield, N. J., has been incorporated with a capital of $25,000 to manufacture and deal in drugs, chemicals, etc. Incorporators are Charles H. Hall, Elizabeth T. Hall and Louis P. Wilson, Plainfield.

T. O. Horne Company, Pleasant Unity, Pa., has been incorporated with a capital of $10,000 to manufacture iron and steel. Incorporator, Mary E. Horne.

Indian Copper Company has been incorporated in Delaware with a capital of $100,000 to carry on business of reducing smelting and mining of gold, silver, copper, etc. Incorporators are Arthur W. Britton, Henry O. Coughlan, George V. Reilly, all of New York.

Independent American Oil & Sulphur Corp. has been incorporated in Delaware with a capital of $15,000,000 to acquire lands containing oil, natural gas, sulphur and other minerals, etc. Incorporators are A. M. Halloran, M. H. Morris, F. Giles, local, Wilmington, Del.

International Alcohol Corporation has been incorporated in Delaware with a capital of $4,000,000 to manufacture alcohol from sawdust, wood wastes and other substances. Incorporators are L. F. Rebori, Frank Cusick and A. Sheard, New York City.

The International Chemical Company, Washington, D. C., has been incorporated under Delaware laws with capital of $100,000 to manufacture chemicals and kindred products. The incorporators are William H. Forman, Thomas J. Hall, Washington, and Charles G. Guyer, Wilmington, Del.

I. G. Jones Co., Inc., Syracuse, N. Y., has been incorporated with a capital of $50,000 to manufacture engines, boilers, petroleum and products, chemicals, asbestos and fireproofing, electrical machinery, plumbers' supplies. Incorporators are I. G. Jones, H. L. Betts, F. C. Faulkner, Syracuse.

The Kaolin Refining Co., 608 Hyde Building, Spokane, Wash., has been incorporated with a capital of $100,000 by D. C. Neatus, Cyrus Rappa and John J. Kyle. The company owns a clay bank north of Spokane, near Deer Park, Wash., containing a large amount of kaolin and ochre. The kaolin analyzed 51.22 per cent silica, 33.52 per cent alumina, 1.72 per cent iron, traces of magnesia, 0.62 per cent alkali, 2.31 per cent fluxes, 1.38 per cent moisture. Loss on ignition, 11.26 per cent. The company intends to build a mill of 30-ton capacity. The mill will be equipped with a flotation plant to separate the grit from the kaolin.

Kenwood Oil Corporation has been incorporated in Delaware with a capital of $10,000,000 to acquire lands containing oil, coal and iron and develop same. Incorporators are A. M. Halloran, M. H. Morris, Ferris Giles, Wilmington, Del.

The Lake Shore Chemical Co., Cleveland, Ohio, has been incorporated with a capital of $200,000. Incorporator, Francis Seiberling.

The Landon Corporation, South Bend, Ind., has been incorporated with a capital of $350,000 to manufacture chemicals and chemical compounds. Incorporators are Georgia V. Landon, Lewis C. Landon, Carl S. Ayres.

The Lignistra Fibre Products Co., Barberton, Ohio, has been incorporated with a capital of $150,000. The incorporator is Kenneth S. Smith.

Linden Chemical Company, Linden, N. J., has been incorporated with a capital of $125,000 to manufacture and deal in chemicals. Incorporators are Adam J. Traub of Elizabeth and Norman W. Kempf and Louis A. Kempf of Newark.

Lippincott Chemical Company, Inc., New York City, N. Y., has been incorporated with a capital of $25,000 to manufacture chemicals, drugs, compounds, etc. Incorporators are W. A. Lippincott, Great Neck, L. I.; B. Berkow, 524 West 34th Street, J. F. Russell, Jr., 43 Cedar Street, New York City.

The Metallograph Corporation, New York, has filed articles of incorporation with capital of $540,000 to operate a refining works for brass, copper and other metals. The incorporators are I. M. Berliner, F. Spungin and J. J. Cohen, 135 West 115th Street.

National Castings Company, Carlisle, Pa., has been incorporated with a capital of $50,000 to manufacture iron and steel. Incorporator: J. H. Foreman, treasurer.

Newcomb Iron & Steel Company, New York, has been incorporated with a capital of $10,000 to manufacture railway equipment. Incorporators are Albert C. Smith, Paul V. Hoyler, Irving H. Schafer.

The Philadelphia Wax Paper Company, Philadelphia, Pa., has been incorporated with a capital of $150,000 to operate a local plant. S. W. Stanage is the principal incorporator.

The Allen W. Phillips Smelting Company has been incorporated with a capital of $50,000 to manufacture steel. The incorporators are Allen W. Phillips, president; Charles Bloss, treasurer, and Dr. Louis Millet, secretary, and others.

The Prestotite Company, Wilmington, Del., has been incorporated with a capital of $50,000 to manufacture and sell "Prestotite" and other chemical compounds.

Radcliffe Color & Chemical Works, Elizabeth, N. J., has been incorporated with a capital of $50,000 to manufacture and deal in colors and dyes. Incorporators are David D. Radcliffe, John J. Smith, Elizabeth; John H. Strawbridge, Hillside Township, Union Cunty.

Rahway Chemical Manufacturing Company, Rahway, N. J., has been incorporated with a capital of $25,000 to manufacture chemicals. Incorporators are I. S. Joseph, G. H. Adler, J. B. Eiseman, Rahway.

The Refractory Magnesite Corporation, New York, has been incorporated in Delaware with capital of $100,000 to operate copper, manganese iron and other ore properties. Arthur W. Britton, Louis H. Gunther and Joseph F. Curtin, all of New York, are the incorporators.

The Rhode Island Foundry & Machine Company, Providence, R. I., has been incorporated with a capital of $100,000. Incorporators are Henry S. Chaffee, Dwight K. Bartlett and Samuel Raynor.

Rockford Union Foundry Company, Rockford, Ill., has been incorporated with a capital of $25,000. Incorporators are Hugo L. Olson, W. A. Brolin, Shelby L. Large.

Rom-Baw Chemical Co., Inc., Clinton, N. Y., has been incorporated with a capital of $25,000 to manufacture furniture polish, varnishes and chemicals. Incorporators are G. H. and M. E. Allen, E. D. Hunter, Clinton.

Sanlis Valley Land & Mining Company, Philadelphia, Pa., has been incorporated with a capital of $3,000,000 to engage in a general mining, milling and refining of ores. Incorporators are F. R. Hansell, J. Vernon Fimm of Philadelphia, and S. C. Seymour, Camden, N. J.

The Stamping Products Corporation, New York, has been incorporated with a capital of $25,000 to manufacture metal molds, etc. C. A. Anderson, S. B. Sherman and G. C. Steeves, 630 West 141st Street, New York, are the incorporators.

The Stanley Vehicle Spring Company, Syracuse, N. Y., has filed articles of incorporation with capital of $100,000 to manufacture steel springs of different kinds. F. W. Green, W. H. Robinson and H. P. Denison, all of Syracuse, are the incorporators.

Sterling Refining Company, Evansville, Ind., has been incorporated with a capital of $10,000 to manufacture sugar, candies and kindred products. Incorporators are Charles F. Hartmetz, Henry A. Wimberg, George P. Stocker.

The Taylor Turpentine Company, Mobile, Ala., has been incorporated with a capital of $100,000. Incorporators are S. and A. Lowenstein and Thos. J. Taylor, H. C. Taylor.

The Texas Production Company has been incorporated under Delaware laws with capital of $1,000,000 to operate oil properties. M. H. Morris, A. M. Halloran and Ferris Giles, Wilmington, are the incorporators of the company.

Texas Sulphur Royalty Company, Wilmington, Del., has been incorporated with a capital of $50,000 to acquire mining claims and develop same. Incorporators are Herbert E. Latter, Henry M. Robinson, Wilmington, Del., Clement M. Egner, Elkton, Md.

Thomas & Betts Co., Elizabeth, N. J., has been incorporated with a capital of $300,000 to act as merchants and deal in chemicals. Incorporators are Robert McK. Thomas, Meandham; Hart D. Betts, Englewood, Adnah McMurtrie, New York City.

Virginia Chlorine Products Corp. has been incorporated in Delaware with a capital of $1,500,000 to manufacture all kinds of dyes, chemicals, etc. Incorporators are C. J. Kulberg, New York; H. Van Arsdale, Newark, N. J.; D. A. Woodcock, Passaic, N. J.

Warren Products Co., Inc., New York City, N. Y., has been incorporated with a capital of $10,000 to manufacture chemicals and drugs. Incorporators are F. L. Cramer, D. K. Hill, H. R. Harrison, 120 Broadway.

The Wilson Oil & Gas Company, Zanesville, Ind., has been incorporated with a capital of $9,000 to sink and operate oil and gas wells. Incorporators are Charles I. Weirich, J. A. Prough, Jasper C. Middaugh, John Miller, James L. McBride.

Wonder Paper & Fabric Company has been incorporated in Delaware with a capital of $2,100,000 to manufacture and sell paper of all kinds. Incorporators are Herbert E. Latter, Henry Robinson, Wilmington, Del., and Clement M. Egner, Elkton, Md.

O. W. Young, Inc., Newark, N. J., has been incorporated with a capital of $25,000 to manufacture and deal in lubricating and illuminating oils. Incorporators are Joseph T. Davey, Kate F. Montrose, Patrick A. Blewith, Newark; Clarence H. Smith, Linden.

Changes of Ownership, Capital, Increases, Etc.

Harrisons' Incorporated, paint manufacturers of Philadelphia, recently purchased by E. I. du Pont de Nemours & Co., have just completed an important purchase which rounds out their business and gives them control of colors and chemicals needed in the manufacture of paint which they have hitherto purchased from other producers. This deal involves an expenditure of about $2,000,000 and gives the Harrison Company control of the Beckton Chemical Company, with plants in Newark, N. J., and in Philadelphia, and of Canby Clark & Co., with plants in Newark, N. J. The Beckton Company was controlled by Canby Clark & Co., and the purchase by Harrisons' Incorporated, includes the stock of both companies. Canby Clark & Co.'s factories manufacture colors for paints, paper, ink, etc., as well as chemicals used in the paint industry. The Beckton Company is a large producer of acids and lithopone.

The American Briquette Company, Philadelphia, Pa., has increased its capital from $25,000 to $200,000 for expansion.

The United States Metals Reduction Company, Pittsburgh, Pa., a Delaware incorporation, has increased its capital from $100,000 to $300,000 to provide for business extensions.

The Fiske Brothers Refining Company, 24 State Street, New York, has increased its capital from $100,000 to $500,000.

The Essex Rubber Company, May and Beakes streets, Trenton, N. J., manufacturer of mechanical rubber goods, has increased its capital from $500,000 to $700,000.

The Simpson Gasoline Company, Bradford, Pa., has increased its capital from $95,000 to $200,000 for expansion.

The Shields Oil & Gas Company, Pittsburgh, Pa., a Delaware incorporation, has increased its capital from $50,000 to $100,000 for extensions.

The Iroquois Foundries, Utica, N. Y., has increased its capital from $25,000 to $75,000 to provide for business extensions.

Construction and Operation

Alabama

BIRMINGHAM.—The United States Steel Corporation has appropriated $11,000,000 for extensions to the plant of the Tennessee Coal, Iron & Railroad Company at Birmingham. The extensions will be used for manufacturing products of commercial use at the present time.

MOBILE.—Several veneer plants have been established recently in the southern part of the State. A new plant will be finished at Ellisville and similar one at Jeffris, La., across the river from Natchez.

Arizona

JEROME.—Actual work on the construction of the United Verde Extension smelter is under way. It is understood that there has been a reversal of the plans for driving a two-mile tunnel and that for some time the ore will continue to be hoisted and delivered to the railroad through a service tunnel at a much higher level. On account of the strike the May output was cut down about 1,000,000 lb. The shortage of production for June will probably be 1,700,000 lb. from the same cause.

Arkansas

LITTLE ROCK.—The Arkansas Lime Company is planning the erection of a $25,000 plant to grind glass sand. The erection of several glass factories at Fort Smith has created a demand for this product.

California

BERKELEY.—The Philadelphia Quartz Co. of Philadelphia has recently incorporated under the California laws and will manufacture silicate of soda in a new plant which will be built here.

MARTINEZ.—The Theodore Dittell Company has commenced erection of a glass-sand, silica and clay refining plant near Antioch. The company will refine glass sand and china clay.

SAN FRANCISCO.—The Amalgamated Paint Co. of New York, manufacturer of marine paint, will establish a Pacific Coast plant to be located on San Francisco Bay.

Colorado

RENO.—Mr. J. C. Moore of New York, together with two engineers, is investigating the possibilities of extracting potash from the waters of Lakes Sumner and Abert, near Lakeview. It is understood that a plant will be erected. A branch railroad will be constructed to connect with the Western Pacific.

Delaware

WILMINGTON.—The Standard Kid Mfg. Company, recently incorporated, has commenced the operation of a plant on Monroe Street for the manufacture of glazed kid and kindred leather specialties. The company has a capitalization of $12,000. The officers, formerly associated with F. Blumenthal & Company, Wilmington, are R. C. McMullen, vice-president, and P. A. Monigle, secretary.

Georgia

SAVANNAH.—The new plant of the Savannah Sugar Refining Company was recently put in operation. The refinery has a capacity of 150,000 tons of sugar annually and is the only one between Philadelphia and New Orleans. The directors are Henry T. Oxnard, Robert Oxnard, James Imbrie, Mills B. Lane, J. H. Hunter, B. A. Oxnard.

Idaho

COEUR D'ALENE.—It is reported that the Coeur d'Alene Mining Company has uncovered 8 ft. of high-grade antimony ore at its Fine Creek property, said to be the largest body of antimony ever uncovered in Idaho. Of the ore fully 3 ft. is first-class shipping product and balance is mill feed free from impurities.

KELLOGG.—Ore to be used in the initial charge of the $1,000,000 smelter of the Bunker Hill & Sullivan has reached the plant, and it is expected that the smelter will begin operations in the very near future. Every section of the big plant is built so that an increase in capacity can be made with the least expense and briefest expenditure of time. The first ore to be treated will be that produced by the company mines, but the opening of the plant to custom trade will make necessary an early expansion. The plant will be in charge of M. H. Sullivan, former assistant superintendent of the Trail Smelter of the Consolidated Mining & Smelting Company, who has had charge of construction of the plant. The company has announced that, effective June 1, all employees of the Bunker Hill & Sullivan smelter were granted a bonus of 75 cents a day. About 3000 smelter employees are affected.

NEZ PERCE.—The plant of the Nez Perce Brick & Tile Factory will begin operations at once. Work of installing machinery has been completed.

Maryland

BALTIMORE.—The Penn-Mary Steel Company is taking bids for the erection of a new one-story concrete copper shop, about 60 x 121 ft.

Michigan

MONROE.—The Monroe Chemical Company will occupy temporarily part of the old Monroe Glass Company for the manufacture of chemicals. The company is a new one.

Montana

BUTTE.—Considerable difficulty is being experienced in the mining district adjacent to Butte by partial strikes at the various properties. The Davis-Daly copper mine, Anaconda Copper Company, the Elm Orlu property, and a number of others have been affected. No disorders of any kind marked the strike, and a number of the men have returned to work.

LIVINGSTON.—H. A. Bacorn and associates have plans under way for the mining of sheelite in Park County. The company plans to immediately open the tungsten and gold mines at Jardine.

New Jersey

BAYONNE.—The National Sulphur Company has awarded a contract for the erection of a two-story reinforced-concrete addition to its plant to cost $20,000. The H. D. Best Company, 52 Vanderbilt Avenue, New York, are the contractors.

BOGOTA.—The Federal Paper Board Company has awarded a contract for the erection of a one-story brick addition to its plant on the River Road.

ELIZABETH.—The Linden Tanning Company, leather manufacturer, is planning the erection of an addition to its plant which will cost $250,000.

HARRISON.—The Crucible Steel Company, South Fourth Street, will build a new one-story shop building about 200 x 400 ft., to be used for forging work. The company will also build a new steel mill in the Lawrenceville district, near Pittsburgh, Pa., to cost about $125,000.

JERSEY CITY.—The Seydel Manufacturing Co.'s plant in which aniline dyes and chemicals were made was destroyed by fire several days ago at a loss of $150,000. A huge pot of benzoic acid boiled over during the fire and caused a great deal of confusion among the workingmen leaving.

NEWARK.—The Alcohol Products Company has had plans prepared for a new plant at the foot of Blanchard Street to cost about $75,000, for the manufacture of alcohol and chemcal specialties. The structures will include a main refining works to be two stories, reinforced-concrete, about 62 x 85 ft., one-story building, 40 x 40 ft., and engine and boiler house for plant operation, 32 x 35 ft. Frederick A. Phelps, Union Building, is architect.

NEWARK.—The Universal Smelting & Refining Company will build a new one-story, brick and steel plant, 110 x 450 ft., at 154 St. Charles Street, to cost about $154,000. The plant will be used for the production of tin, lead, etc. Plans for the erection have been filed.

NEWARK.—The American Leather Mfg. Company, 488 Frelinghuysen Avenue, has filed plans for the erection of two one-story additions to its plant at New and Nuttman Streets, about 25 x 45 ft., and 11 x 35 ft., respectively.

NEWARK.—The Dooner & Smith Chemical Company, 258-60 New Jersey Railroad Avenue, has filed plans for the construction of a one-story addition to its plant, about 50 x 86 ft.

NEWARK.—H. F. Sommer & Company, 219 Hamburg Place, manufacturer of leather, has filed plans for the erection of a new one-story tannery addition.

NEWARK.—The General Alloy Company, 59 Bruen Street, has filed notice of organization to operate a local plant for the production of different alloys. Davis Rosen is head.

NEWARK.—J. L. Armitage & Company, 51 Dawson Street, manufacturer of paints and varnishes, will build a one-story reinforced-concrete addition to its plant, about 30 x 60 ft.

NEWARK.—The Celluloid Company has filed plans for the erection of a one-story addition to its plant, about 30 x 69 ft., at 51 Westcott Street.

RIDGEFIELD PARK.—The Bergen Paper Company will build a two-story addition to its plant, about 60 x 85 ft., to cost $15,000.

New York

LEROY.—The LeRoy Electric Porcelain Company will increase the capacity of its plant for the manufacture of electric porcelain specialties. Four new kilns will be erected.

LOCKPORT.—The Lockport Paper Company, Mill Street, manufacturer of paper, will build a one and two-story reinforced-concrete addition to its plant, about 40 x 110 ft. Harry Nichols is general manager.

LOCKPORT.—The Simonds Mfg. Company, Ohio Street, manufacturer of saw steel, will build a one-story extension to its plant, about 55 x 165 ft.

WATERTOWN.—The Brownsville Paper Company will erect a large addition to its plant this summer.

Ohio

CINCINNATI.—A company to be known as the Elferose Sugar Company has been formed for making a special kind of sugar and syrup not now attainable in the United States. J. W. Freiberg of the Freiberg & Workum Company, is interested.

Oregon

OREGON CITY.—A strike of 100 employees of the Crown-Willamette Paper Company, resulting in complete close-down of the mills, has been settled satisfactorily. Coincident with the settlement the company announced a bonus of 50 cents a day for all its employees, effective June 1. New bonus takes the place of a graduated bonus of from 50 to 25 cents, based on the wage rate of the employee, which has been in force for some time.

ROSEBURG.—Charles W. Jones of Portland, expects to establish a fertilizer plant on the property of the Oregon-Portland Cement Company near Roseburg. It is said the property contains an unlimited supply of lime rock suitable for manufacture of farm products, and a plant costing $100,000 is to be installed.

Pennsylvania

EASTON.—The Standard Processing Steel Corporation has increased its capital from $300,000 to $500,000 for expansion. It is proposed to increase the capacities of the present steel and iron foundries; the output of the latter department will be doubled. The work is estimated to cost $100,000. O. L. Mills is president.

PHILADELPHIA.—The Penn Chemical Company has awarded a contract for the erection of a three-story brick and concrete addition, about 25 x 50 ft., on Washington Avenue. The new works, with power house, will cost $75,000.

PHILADELPHIA.—J. F. Johnson & Company, operating automobile repair shops at 2317 North Sixteenth Street, are taking bids for the construction of a new two-story garage and tool shop, 30 x 115 ft., at Ninth and Tioga Streets.

PHILADELPHIA.—C. F. Simonin's Sons, Tioga and Belgrade Streets, manufacturers of oils, etc., have awarded a contract for the erection of a one-story addition, about 75 x 90 ft., to cost $15,000.

PHILADELPHIA.—Fire recently destroyed a portion of the plant of the Barrett Manufacturing Company, Tucker and Bermuda Streets, with loss estimated at $10,000. The plant will be rebuilt.

PHILADELPHIA.—The Crew Levick Company, Land Title Building, manufacturer of oils, has commenced the preparation of plans for its new oil plant to be located on Pettys Island in the Delaware River, opposite Philadelphia, to comprise about ten buildings. This company is one of the properties of Henry R. Doherty Company, 60 Wall Street, New York.

PHILADELPHIA.—The India Refining Company, Swanson and McKean Streets, manufacturer of refined oils, has filed plans for the erection of an addition to cost about $25,000.

PITTSBURGH.—The Knox Pressed & Welded Steel Company of Wheatland and the Blaw Steel Company of Pittsburgh have combined. The new firm is to be known as the Blaw-Knox Steel Company and will be capitalized at $1,400,000. The Blaw company has a large plant in Pittsburgh, where it manufactures steel and copper and other products. The Knox plants are located in Sharon and Wheatland.

PITTSBURGH.—The Damascus Bronze Company, 929 South Avenue, manufacturer of brass and bronze castings babbitt metal, etc., has filed plans for a new one-story foundry on Reedsdale Street to cost about $25,000.

WARREN.—The Warren Oil Company has acquired about ten acres of property near the city and plans for the construction of a new oil and blending works to cost about $50,00.

Tennessee

CHATTANOOGA.—The Chattanooga Gas & Coal Products Company will increase the capacity of its coke manufacturing plant at Alton Park by the installation of 24 new ovens, at an estimated cost of about $300,000. The plant will have a capacity of about 300 tons of coke daily. The Semet-Solvay Company, Solvay, N. Y., has the contract for erection.

Utah

SALT LAKE CITY.—A new company known as the Western Phosphate Mining & Manufacturing Company, will locate a plant near Paris, Idaho., in a field of phosphate rock.

Virginia

LYNCHBURG.—The Glamorgan Pipe Foundry Company has awarded a contract for the erection of an addition to its plant, about 40 x 80 ft., to cost $20,000.

NEWPORT NEWS.—The War Department has awarded a contract for the construction of a large manufacturing plant to make hydrogen for balloons. The gas will be made at the Government aviation station.

Washington

EVERETT.—The Western Talc Company here recently began work of opening a large body of talc near Reardan, Wash. The company will begin shipping as soon as machinery for the mill has been installed.

MORTON.—A. R. Rutherford, here, announces that the group of cinnabar mines near Morton have been sold to a new concern and that a large crew of men will be put at work immediately to reduce the immense quantity of low-grade ore in sight to quicksilver.

SPOKANE.—The Humane Stock Remedies Company here will immediately rebuild its lime-sulphur solution plant which was destroyed by fire on May 17, the new plant to have a capacity double that of the old one. The company will also build and equip a large new furnace room.

SPOKANE.—Northwestern Magnesite Company of Spokane has awarded a contract for the construction of a tramway 25,000 ft. long. The net fall is 430 ft. and the capacity 60 tons per hour. The tramway will deliver magnesite from the company's properties to their mill near Chewelah, Wash. The tramway will be built by the Riblet Tramway Comany, who will also build a tramway for the Engels Copper Mining Company of Engels, Cal.

TACOMA.—By combining two small plants and doubling the stock and number of workmen employed, S. Menefee, manager of W. P. Fuller & Company here, has created the largest plant in the Northwest for the manufacture of mirrors, art glass and bevel plate. The two plants consolidated are the Myhern Company and Destiny Art Glass Works, both on A Street, Tacoma. The enlarged plant has been located in the Ferguson Building at 1205 A Street, and will be known as Fuller's Art Glass, Mirror & Bevel Plate Works, a branch of W. P. Fuller & Co.

West Virginia

CLARKSBURG.—Many new companies are coming to West Virginia for coal in spite of the natural gas shortage. The shortage of natural gas in several other States has caused industrial companies to pick locations where coal is readily available.

WHEELING.—The Hazel-Atlas Glass Company plans another addition to its plant.

British Columbia

AINSWORTH, B. C.—The concentrates of the Silver Hoard mine here are running high, according to report of W. S. Hawley of Spokane. Concentrates show 65 per cent lead, 150 ounces in silver and 45 per cent zinc. As soon as machinery is adjusted it is expected this can be raised to 70 per cent lead and 50 per cent zinc, with a recovery of 85 to 90 per cent. The flotation plant will begin operation July 1.

KAMLOOPS, B. C.—The local board of trade has approached the Provincial Government for the construction of a smelter in this district for the treatment of low-grade ores. The Minister of Mines announces that it is not the intention of the government to erect any smelters in 1917, but the claims of Kamloops will be investigated.

NELSON.—The Molly Mine, next to the largest molybdenite mine in Canada, is to be immediately equipped with a large mill. Figures show that the mine ranks second as the largest producer of molybdenite and one of the most important of the country's munition properties.

NEW WESTMINSTER.—The Western Canada Lime Company has achieved considerable success since its opening. Plant has been handicapped by lack of available labor, but its product, pulverized lime rock, has been very popular.

PENTICTON.—The Canada Copper Corporation, Mr. Ashmund, general manager, is completing plans for equipping the mine at Copper Mountain for a production of 2,000 tons daily; installation of a power plant, and mill capable of handling this tonnage. About 600 employes will ultimately be required. Mill will be built on the Similkameen River and the oil flotation process will be used.

PORT COQUITLAM.—Voters will shortly pass on a by-law to be submitted to them to bonus the proposed steel works plant to the extent of $200,000, of which A. F. Bernstein of Vancouver, and associates, will be the founders. The proposition is that the Steel Company shall spend $800,000 in the establishment of a plant to turn out 75 tons of steel daily.

TRAIL.—In spite of lack of coke, shortage of labor, high costs of operation and other difficulties, the big smelter and refinery here has continued to handle ore. During the last week in May 5669 tons of ore were received at the smelter. The total for the month of May, however, dropped to 15,364 tons, the lowest of any month during the year.

TRAIL.—It is expected that the new concentrator of the Consolidated Mining & Smelting Company here will be completed. The equipment of machinery installed, and the plant in operation. Wilfley tables and other machines are now being placed and arrangements made for using the oil flotation process in the concentration of the company's Sullivan mine complex ores, for which the plant is primarily intended. The plant will have capacity of 200 tons daily, and is erected as an experimental plant. If successful, a much larger plant will be erected.

VANCOUVER.—One unit of the Pacific Mills, Ltd., at Ocean Falls, capable of producing 75 tons of newspaper stock daily, has been put into operation. This plant is the first unit of an ultimate development of 195 tons.

VANCOUVER.—Hematite Mining Company has been reorganized with capital stock of $45,000.

VANCOUVER.—The Canadian Collieries are building 150 coke ovens at Union Bay. It is expected that the Kootenay-Boundary smelters will be able to get some coke from the coast.

VANCOUVER.—The Rainy River Pulp & Paper Company has commenced manufacture of paper at its Port Mellon, Howe Sound mill, the first four units of the plant having begun operation. The plant was changed in record time from a soda process mill to a kraft process mill, having been bought by Eastern capitalists early in February. It is the only plant using the kraft process on the Pacific Coast.

VICTORIA.—Hon. William Sloan has introduced a bill in Legislature to permit the department of mines to go into the smelter business if warranted, urging its passage as a means of further developing the natural resources of the province.

VICTORIA.—The Hardy Bay Coal Company here has been organized with a capital stock of $1,000,000, with the object of acquiring, developing, operating, working and selling mines, mineral claims, mining properties and petroleum claims, and the treating, refining and marketing of mineral coal or oil therefrom.

Manufacturers' Notes

BRITISH REGULATION OF SULPHURIC ACID.—Important orders have been issued from the British Ministry of Munitions bearing the date of May 29, 1917, regulating, in all respects, the manufacture and sale of sulphuric acid. The order, according to *Commerce Reports*, says that

1. No person shall as on and from the 11th of June 1917, until further notice, manufacture sulphuric acid except under a license issued by or under the authority of the Minister of Munitions and in accordance with the terms and conditions of such license as to the quantities to be manufactured or otherwise.

2. No person manufacturing sulphuric acid shall as on and from the 11th of June, 1917, until further notice, use during any one calendar month more than 10 tons in all of 75 per cent sulphuric acid (or its equivalent in acid of other strengths) for the purpose of all other manufactures, trades and businesses carried on by him except under and in accordance with the terms and conditions of a license issued by or under the authority of the Minister of Munitions.

3. No person shall as on and from the day following the date of this order, until further notice, supply sulphuric acid (including waste sulphuric acid) to any person except under and in accordance with the terms and conditions of a license issued by or under the authority of the Minister of Munitions. Provided that no license shall be required to supply not more than 56 pounds of 95 per cent sulphuric acid (or its equivalent in acid of other strengths) to any person during any one calendar month. And provided also that any sulphuric acid supplied subsequently to the date of this order in pursuance of written directions or requests given or made by or on behalf of the Minister of Munitions previously to the date of this order shall, unless and until such written directions or requests are canceled or withdrawn, be deemed to have been supplied under a license issued under the authority of the Minister of Munitions within the meaning of this order.

The order also states that no manufacturer of sulphuric acid or agent of such a manufacturer shall charge or receive in payment for any sulphuric acid supplied by or through him a price exceeding a maximum specified in the order.

NATIONAL ANILINE & CHEMICAL COMPANY, INC., ELECTS OFFICERS.—The officers and directors of the new National Aniline & Chemical Company, chosen at the recent meeting, are as follows:

Chairman of the Board, William H. Nichols, president, J. F. Schoellkopf; first vice-president, William Beckers; second vice-president and treasurer, I. F. Stone; third vice-president, Hugo Schoellkopf, and secretary, William H. Miller. The directors are J. F. Schoellkopf, J. F. Schoellkopf, Jr., Hugo Schoellkopf, all of the Schoellkopf Aniline & Chemical Works, Inc.; William Beckers, Eugene Meyer, Jr., Charles J. Thurnauer of the W. Beckers Aniline & Chemical Works, Inc.; William H. Nichols, Henry Wigglesworth and J. M. Goetchius of the General Chemical Company and Benzol Products Company; T. M. Rainhard and W. N. Mellravy of Barrett Company and Benzol Products Company; H. H. S. Handy and E. L. Pierce of Semet-Solvay Company and Benzol Products Company. Mr. Meyer and Mr. Thurnauer also represent the firm or Eugene Meyer, Jr., & Co., and I. F. Stone the National Aniline & Chemical Company.

The capacity of the company will be more than 30,000,000 pounds annually, and expansions are going on rapidly. The offices have been at 244 Madison Avenue since July 1.

DU PONTS MAY ENTER DYESTUFF FIELD.—The Du Pont company is planning to enter the coal tar dye industry. The company has been investigating the dye situation for a long time. Its chemists were at work before the war, and when the foreign supply was cut off their efforts were redoubled. The Du Pont company has adequate laboratory facilities and large plants already equipped, so that delay for building operations is unnecessary.

VEGETABLE OIL INDUSTRY OF UNITED STATES.—Director Samual L. Rogers of the Bureau of the Census has issued a summary showing the production in the United States of edible vegetable oils other than cottonseed for the calendar year 1916.

There were received reports of 112 concerns in the United States in 1916 which manufactured 262,558,661 lb. of oil from peanuts, mustard seed, kapok seed, rape seed, sunflower seed, soya beans, walnuts, corn, copra, palm kernels, and olives. The movement to grow soya beans, peanuts and other oil-bearing seeds and nuts other than cottonseed for the manufacture of oil has received a great impetus and there will probably be several hundred establishments engaged in crushing the crops grown in 1917.

In addition to the production of home vegetable oils, which may be used for edible purposes, considerable quantities are also imported. During the calendar year 1916 there was imported 64,349,308 lb. of cocoanut oil, 16,587,755 lb. of cottonseed oil, 145,469,289 lb. of soya-bean oil, 295,270,663 lb. of palm oil, 1,323,737 lb. of palm-kernel oil, 2,089,801 gal. of peanut oil, 2,690,755 gal. of rape-seed oil, 7,686,593 gal. of Chinese-nut oil, and 5,815,578 gal. of edible olive oil. During the same period there was exported 188,213,816 lb. of domestic cottonseed oil, and 9,118,812 lb. of corn oil; also 478,438 lb. of foreign cocoanut oil, 3,062,900 lb. of soya-bean oil, 46,805 lb. of palm oil, 22,780 gal. of peanut oil, and 52,265 gal. of edible olive oil.

TO ASSURE SUPPLIES OF PALM OIL.—A meeting was held at the Bureau of Foreign and Domestic Commerce in Washington last week which was attended by representatives of the tin-plate makers, soap makers, and palm oil importers, to arrange for an ample supply of palm oil for American industries.

A committee will be formed and the palm oil will be shipped direct from the west coast of Africa to the United States, instead of first going to England. In return for permitting exportation of oil, Great Britain is to receive its equivalent in glycerine content, which is 6 per cent.

THE GREAT WESTERN SMELTING & REFINING COMPANY of St. Louis has opened a Denver office at 312 Century Building, Denver, Col., their representative being Maxwell M. Levy. Orders will be taken from the Denver office and the shipments made either from the Chicago or St. Louis plants. The products offered by this company are: Babbitt, solder, pig lead, tin, antimony, copper ingot, brass ingot, aluminum ingot, phosphor tin, phosphor copper, stereotype, linotype, electrotype and monotype.

SODIUM NITRATE.—Marden, Orth & Hastings Company, Inc., of 61 Broadway, New York, are sole selling agents of the American Nitrogen Products Company, who are making sodium nitrate by the fixation of atmospheric nitrogen.

NEW CHICAGO RESEARCH LABORATORY.—The Research Laboratory of Chicago has recently been incorporated. This is an Illinois corporation, having a stock of $50,000. It is organized for the purpose of carrying on research work in the development and exploitation of chemical processes. The company also expects to engage in the manufacture of some pharmaceutical and photographic chemicals. The incorporators are W. S. Shaw, H. McCormack, A. G. Wackenreuter of Chicago, George S. Rice of Petosky, Mich.; F. S. Howse of Boston, and E. C. Klipstein of New York. Mr. Klipstein is president of the company, and Mr. McCormack will act as manager.

CARLISLE, PA., WANTS CHEMICAL INDUSTRIES.—Manufacturers about to enter the chemical field for the manufacture of dyes and other chemical products will be interested in an announcement received from the Carlisle Chamber of Commerce. Carlisle, Pa., that their city is making a very strenuous effort to secure the location of desirable chemical enterprises. The peculiar atmospheric conditions existing in Carlisle have been determined by expert engineers employed by the Chamber of Commerce as adaptable in every respect for the chemical industry.

In addition to the natural facilities, free factory sites, financial assistance, and a very low electric rate of $.011 per k.w.h. one of the lowest rates in the State of Pennsylvania, competent employees of all grades can be secured in Carlisle, and with its location, Baltimore Freight Classification, situated on two railroads, is one of the most advantageously located cities for distribution of chemicals in southeastern Pennsylvania.

NEW ELECTRIC FURNACE COMPANY.—The Booth-Hall Company has been formed to conduct an electric furnace building, engineering and metallurgical business with offices at 565 West Washington Blvd., Chicago. The new company is composed of five former officers and employees of the Snyder Electric Furnace Company. Mr. C. H. Booth, formerly president of the Snyder Electric Furnace Company, Chicago, will be president and general manager of this new company. Mr. W. K. Booth, formerly vice-president of the Snyder Electric Furnace Company, and who for many years was in charge of the engineering and metallurgical work for that company, is to be metallurgist for the new company. Mr. Julius R. Hall, formerly secretary, mechanical engineer and production manager of the Snyder Electric Furnace Co., will be vice-president of the new company and have charge of similar work for them. Mr. Hall was for many years designing engineer of the Strauss Bascule Bridge Company, Chicago. Mr. W. D. Walker, formerly sales manager of the Snyder Electric Furnace Company, will be sales manager of the new company, and Mr. F. J. Sheldon formerly auditor of the Snyder Electric Furnace Co., will be secretary.

The company has applied for patents on an electric furnace to be called the Booth-Hall electric furnace. This will be designed in three different types to suit the metallurgical conditions of the individual customer and to operate either one, two or three phase, as will best work out in each case. It is the intention of the new company to make a special study of the needs of its customers, and to be in a position to recommend the type of equipment best suited for the work to be done.

Experience has shown that frequently a three-phase furnace will work to better advantage on certain grades of steel than single phase, and other times a simple single-phase type of equipment is to be preferred.

The company has already closed a contract for a four-ton, two-phase, Booth-Hall furnace, which is to be the first unit in a newly formed electric steel company.

THE INDUSTRIAL ELECTRIC FURNACE COMPANY, organized under the laws of the State of Indiana, has acquired the business of the Snyder Electric Furnace Company and the Snyder patents and designs of electric furnaces and processes. The directors of the new company are Charles B. Sommers, Stoughton A. Fletcher and Charles B. Fletcher of Indianapolis and F. Von Schlegell and F. T. Snyder of Chicago. The business organization is new and the company will start with a large engineering force and will take up the manufacture of electric furnaces for steel work, will enlarge the plant at Clearing both for electrometallurgical developments and for the commercial production of electric furnace products. Mr. Snyder, who will be interested in and associated with the new company as engineer and metallurgist, has had many years of experience in the electric furnace field. The executive officers of the company will be F. Von Schlegell, president, and Charles B. Fletcher. The offices of the new company will be at 53 West Jackson Boulevard.

Manufacturers' Catalogs

THE STIMPSON EQUIPMENT COMPANY, Salt Lake City, Utah, has issued an attractive catalog on the Janney flotation machine for the treatment of ores by the flotation process. This booklet describes two types of Janney flotation machines and is illustrated by diagrams of the machines showing the different parts and also machines installed in different plants.

THE UNION SWITCH & SIGNAL COMPANY, Swissvale, Pa., has issued Bulletin 87 describing its forge plant.

THE JAMES ORE CONCENTRATOR COMPANY, 35 Runyon Street, Newark, N. J., has issued Bulletin No. 1, Section A, describing its concentrating tables.

THE PREST-O-LITE Company, Indianapolis, Ind., has issued a new catalog describing its apparatus for oxy-acetylene welding and cutting.

Other New Publications

MOTOR GASOLINE; PROPERTIES, LABORATORY METHODS OF TESTING AND PRACTICAL SPECIFICATIONS. By E. W. Dean. This is a Bureau of Standards publication, Technical Paper, 166.

THE ACTIVATED SLUDGE PROCESS OF SEWAGE TREATMENT. By J. Edward Porter of the General Filtration Company, Rochester, N. Y. This book gives a bibliography of the subjects with brief abstracts, patents, news items, etc., compiled from current literature.

MAGNETIC AND OTHER PROPERTIES OF IRON-ALUMINUM ALLOYS MELTED IN VACUO. By Trygve D Yensen and Walter A. Gateward. This is Bulletin No. 95 published by the University of Illinois, Urbana Engineering Experiment Station.

LIST OF PUBLICATIONS OF THE DEPARTMENT OF COMMERCE AVAILABLE FOR DISTRIBUTION. The fifteenth edition of this book, issued May 8, 1917.

THE MINING INDUSTRY IN THE TERRITORY OF ALASKA DURING THE CALENDAR YEAR 1915. By Sumner S. Smith. Bulletin 142 issued by the Department of the Interior, Bureau of Mines.

THE COAL-FIELDS AND COAL INDUSTRY OF EASTERN CANADA. By Francis W. Gray. Bulletin No. 14, published by the Canadian Department of Mines, Ottawa.

ANNUAL REPORT OF THE MINERAL PRODUCTION OF CANADA DURING THE CALENDAR YEAR 1915, published by the Canadian Department of Mines, Mines Branch, Ottawa.

Metallurgical and Chemical Engineering

On the Progress of the War

One of the most popular "indoor sports" of the season seems to be criticizing the activities, or lack of activities, of some particular governmental department, spouting out virtuous indignation at the lack of co-ordination exhibited generally, and predicting disaster for our cause from procrastination and diffusion of energy. And indeed, it seems at times as though the man on the street has ample grounds for complaint. First, he observes certain elected legislators practising law in the Senate, obstructing essential legislation, creating boards—long, narrow and wooden—for positions needing centralized authority in the hands of one energetic administrator; investigating suspiciously and even vilifying the personality of any man or committee who really gets things done without asking for advice, all in a manner highly pleasing to the Imperial German Government. Next he observes interminable squabbles between Denman, lawyer, and Goethals, canal builder, on the proper way to build up a merchant fleet, they meanwhile doggedly forgetting that they are connected with an *Emergency* Fleet Corporation. And as a final straw he observes the spectacle of one cabinet member branding as exorbitant and impossible a coal-price tentatively fixed at a conference between a brother cabinet member and a large number of coal producers, even after a third member of the cabinet had told the conference to be careful not to do anything in restraint of trade, in effect warning them against doing anything and yet saying that something must be done.

This lack of co-ordination is only natural. Happily, the American democracy has not the highly centralized ("efficient," if you will) legislative, administrative and judicial branches of the German "democracy." Nor have we for years been bending every energy, adapting every industry, training every son, co-ordinating every activity, suborning all education toward "der Tag," when we at last would smash our way into our place in the sun. Our Government was built on the practices, ideas, and ideals of peace, and such an intricate structure cannot face about sharply to the pursuit of war without sundry creaking in the joints, clattering of furniture, and general dislocation.

We would therefore counsel patience. Put yourself in his place. Most of the troubles appear to arise from a lack of fixed, definite, and coherent war policy. The change in function of our various governmental departments is no more radical than these: Suppose that a sugar expert should suddenly be transported to the center of a powder factory, or that a cyanide man be

given charge of an electrical steel-furnace, each with the admonition that he take hold, make a record production, and, above all, get busy *quick*. Would there not be an extreme liability for diverse and sundry flashes, a falling off of the power factor, accompanied by more or less short-circuiting and various other fireworks?

Unless the man were absolutely worthless the best he could do would be to call in various disinterested experts, familiar with those details strange to him, and accept and act upon their advice. We may be thankful for the assurance that notwithstanding the suspicions of certain Senators, this is being done to an extent before undreamed of; red tape and tradition is being thrown aside in large volume, and replaced by common sense and progress. The informed engineer even sees reassuring evidence of co-ordination between governmental official and technical advisers in Secretary Baker's recent statement that only $4,000,000 of the $20,000,000 available for a nitrate plant would be expended at this time. The Government is apparently hesitating before it embarks upon the development of a water power nitrate-plant, and in this is wisely following expert opinion given originally by the Committee on Public Relations of the American Electrochemical Society just a year ago. Doubtless, the Department is wisely keeping the precise plans very secret, and it is impossible to form an opinion as to the process or processes it intends to utilize. It is safe to say, however, that if some power-consuming process be adopted, there will be means for securing the necessary electricity instantly from systems at present constructed and operating without the necessity of delaying production until a large dam and hydro-electric station can be installed, a matter taking at least a year of the speediest construction. Here again there seems but little justification for the fulminations of the daily press upon the lack of enterprise in essential preparations.

Finally, one should not forget that a censorship prevents the publication of news about the *accomplishments* of a nation at war; only the obverse and darker side of the picture is held up for public inspection. We therefore recommend a little stabilizing trip for the man who looks about him and sees no evidence of war-activity, when he gets to seeing and purveying only gloom. Let him run over to one of the training camps for the officers' reserve, or to a concentration camp for the new army, or to an aviation school. Even if a watchful sentry prevents him from getting very close to the hive of activity, still he can absorb a different and saner viewpoint by contact around the edges.

Regulating Steel Prices

Everyone knows, first, that there is a controversy between the authorities at Washington and the steel manufacturers over the price the Government should pay for such steel as it needs to prosecute the war, and second, that there is a disposition, or a desire, in Washington to fix maximum limits for the price of steel that may be sold to private consumers. Beyond this nobody seems to know anything. The parties are maneuvering for position and will not commit themselves to anything specific. If the public undertakes to draw inferences as to their real intentions, a hopeless puzzle results. Washington does nothing but wield the big stick it picked up at the beginning of the war: "Cost plus 10 per cent!" while the steel makers allow it to be assumed that they are contending for a price in relation to the present market, whereas in fact there is no regular market in existence.

Neither party is serious. It is simply maneuvering. Let us see what "cost plus 10 per cent" would mean. Using a weighted average of the finished steel products, the lowest selling price in the past 15 years was about 1.42 cents per pound, in December, 1914. There were practically no profits then, but on a full output there would have been some profit. Then, assuming 1.30 cents as the average cost, 10 per cent profit on an output of 31,000,000 gross tons a year would net $90,000,000 for the American steel industry. In the United States Steel Corporation's four poorest years in its 16 years' history it averaged about that amount, with an output barely more than one-fourth as great. The steel industry cannot possibly turn its capital fast enough, having such a large investment per ton of output.

Now if there is a market at present, what is it but the price at which one can buy for delivery not longer than a few months hence? That would be 4½ cents or more for bars and shapes, about ten cents for plates, perhaps nine cents for sheets, and various other prices beyond all market precedent, even the precedent of a few months ago. The weighted average already used would work out not less than six cents per pound of steel. Even if the cost of production has increased 50 per cent, which of course it has not, the profit on a year's output would be two and three-quarter billion dollars, or an amount quite close to the total capitalization of the industry.

The three heavy products in the steel industry are bars, shapes and plates. The average market price in the ten years 1905 to 1914 inclusive was: Bars, 1.385c.; shapes, 1.472c.; plates, 1.456c., an average of 1.44c. Profits must have been fairly satisfactory as dividends were paid and new plants built from earnings. Chairman Denman of the Shipping Board set 2.50c. as the price to be paid for bars, plates and shapes for the merchant ships the Emergency Fleet Corporation is to build. If 1.44c. were the production cost, the profit at 2.50 cents would be such that, if applied to the entire steel output, the total would be about $730,000,000, or more than double the Steel Corporation's earnings last year—those earnings having been more than double the earnings in any previous year. In passing, it might be noted that the Steel Corporation produces approximately one-half the country's steel output.

One reason for the rejection of Chairman Denman's proposed prices was doubtless that if they were agreed upon an effort might have followed to force the prices down farther. Another reason, of course, was that plates, the commodity chiefly needed, were put at the

same level as bars and shapes, whereas market conditions have long established a much higher price for plates than for the other commodities. Doubtless another reason was the danger that if such prices were arranged for Government steel, there might be another step; to fix prices for all buyers at the Government level.

Thus there is no indication that the two parties are defining their position so as to reach a common ground. The measure should be the amount of profit it is fair that steel producers should make in times like these. Should the profits be larger or smaller than those of 1916? In that year they were almost three times the average profits of 1912-13-14, which figure is taken in the Senate law as being the basis for computing "excess profits." If 1916 be taken as a standard from which to make a departure, it might then be determined whether or not extra profits should be allowed sufficient to cover the excess profits tax, leaving the steel producers with the same net earnings as before. To the average prices realized in 1916 there could be added an amount equal to the increase in cost of production, not especially difficult to ascertain. The result would be a schedule of prices applicable both to the Government and to private consumers, in accordance with the "one price to all" doctrine enunciated by President Wilson in his statement made public July 12.

Wanted:—An Industrial Army

The thoughtful observer is depressed by the continual news of strikes, large and small, which appears from all sides. Few of them involve a considerable body of men actually on strike, but in their influence on allied and subsequent manufacturing processes it is quite probable that they are materially affecting the volume of some much-needed output. The refusal of a few dozen electricians or hoisting engineers to continue work in some mining district could very easily paralyze production—not a miner could work, if he would. Immediately smelter receipts will be curtailed, causing partial or complete shutdown, which in turn is reflected in a diminishing refinery output. Only one or two weeks ago a strike among machinists in the shipbuilding yards near New York threatened a complete shutdown of this most essential construction.

It is not a question of the laborer lacking patriotism. The patriotism of the American citizen, be he workman or employer, is beyond suspicion; unfortunately, however, he fails to realize the full consequence of his attitude. We are all heartily in favor of economy, as long as it doesn't interfere with our comfort or our business. All of the manufacturers are pointing with pride to their willingness to co-operate with the Government as to price and production, while Wall Street trembles to a falling market. The press is anxious to raise a large part of the war budget by taxation as long as the postal rates are not increased. The American farmer is glad to produce wheat enough to feed the world at a minimum price of two dollars a bushel. The American unionist will cooperate with the Government in a closed shop.

We have yet only dimly glimpsed what this war is going to mean to each of us; we have not yet a shadow of the profound effect it will have on our public and private life, habits, and character. For compulsion, that ugly thing, has come into our state, hand in hand with his uglier master, war. Martial law is supplanting civil law. A conscript replaces a volunteer. Price-fixing supersedes the law of supply and demand. Commandeering guarantees adequate output.

But how can even a commandeered factory produce munitions without workmen? And who is to certify that machinist Stillson will take orders from Foreman Trott any more willingly to-morrow when Superintendent Brisk receives directions from under-secretary Tape than to-day when Brisk is in touch with managing-director Bond? He is still working in the same old shop, at the same old machine, turning out the same old product, cussed by the same old bosses, getting the same old pay envelope, and listening to the same old agitators.

It seems a pity that the Government is not to utilize the key to the labor situation, which is already in its hands, ready for adaption, in the draft law. Men with families will not be called into military service, principally because it is more economical to leave them behind to take care of their dependents. But simply because such a man is exempt from combatant duty, he should by no means be exempt from *service*. How simple it would be to enlist him into an industrial army—divisions of farmers, blacksmiths, carpenters, miners, trades and occupations of all sorts, organized for *service*, enlisted in our cause, ready to go where they are needed, and to work with their hands and brains in turning out the munitions so essential to the war.

Such a mobile industrial army would have a profound moral as well as material effect at the first hint of labor trouble. Unanimity would be impossible because a certain proportion of the men would already be drafted into the industrial army. They *could* not quit, short of treason. Any other man of divided allegiance would be assured that when he left work, there would quickly appear soldiers of the United States of America, willing and ready to do their bit to help win the war by maintaining production.

Commandeering of both plants and labor is as essential to the conduct of our war as is conscription of the army, and as inevitable. It might appear difficult, if not impossible, to decide such questions as, "What industries are essential?", "What particular portions of these industries should be commandeered?", "What trades within these factories should be fool proof?", "Where and when shall we move our 'soldiers of peace'?". The determination of such matters will sooner or later be placed in the hands of a well-organized Department of Munitions and Production—why not do it sooner?

The organization of this industrial army would be comparatively simple. The mechanism of its selection is already in our hands. Why not use it?

Sampling vs. Correct Analytical Results

To the Editor of Metallurgical & Chemical Engineering

Analytical chemists in U. S. A. have lately been much agitated over the discovery that certain widely-advertised chemicals used for laboratory purposes are not so pure as their labels indicate, and a discussion upon the value of "analyzed chemicals" has taken place in the press, and also before some sections of the American Chemical Society. This discussion proves once again that the sampling of any commercial product is quite as important as the analysis of the sample when obtained, and that more supervision ought to be given to the preliminary work of selecting and preparing the sample.

As a chemist of considerable experience in manufacturing work and with a knowledge of the conditions that usually obtain when samples of bulk-deliveries are taken for analysis, the writer can state that in nine cases out of ten, this work is entrusted to youths or men with insufficient training and knowledge for the work. Very many of the disputes that arise between the sellers and buyers regarding the purity or strength of the commodities sold, are due in fact not so much to the inaccuracy of the analytical methods, as to inaccurate sampling.

The widely prevalent idea that any man or youth provided with the necessary tackle can be trusted to produce a fair and accurate sample of a manufactured chemical product without any supervision, must be eradicated before progress toward greater accuracy can be attained.

There are instances no doubt, in which the chemist himself cannot spare the time necessary for constant supervision of this work, as in the case of large purchases of ores, shipped by sea or rail in bulk. When this is the case, the oversight of the sampling must naturally be delegated to some competent and intelligent man, who has been well-trained in the theory and practice of sampling, by the chemist whose place he is to take. Since attempts to bribe samplers are by no means uncommon, a man of strong character and stiff moral backbone should be selected for the job.

As regards the common faults of sampling, there are three conditions which must be observed, if a fair sample of any commodity is to be obtained:

(1) The original sample taken must be large enough to represent all portions of the bulk, and a fair proportion between large and smalls must be maintained.

(2) The sample must be reduced by repeated crushings, mixings, and quarterings, to the small quantity required for the actual test.

(3) In order to continue the crushings and quarterings up to the required degree of fineness, it is necessary to dry the sample at some intermediate stage. A wet or damp sample cannot be ground to pass through a 60-mesh brass wire sieve used for the final stage of sampling.

Conditions (1) and (3) are those which are most often neglected in practice by those entrusted with the sampling operation. The first calls for the exercise of careful judgment and considerable intelligence on the part of the sampler, while the third demands great patience, especially with ores and other hard materials. The crushing and passing through the sieve of the last portion of the sample is the most important part of the sampler's work, since in many cases the impurity is harder than the pure substance, and to throw these last fractions of the original sample away, because they are difficult to grind, is a fatal error.

In conclusion, it may be stated that the need for some greater degree of uniformity in sampling methods is urgent. Chemists as a class have recognized the necessity for standardization of their methods of analysis, but the equally important work of sampling has been left too long in the hands of the ignorant, and until this is remedied by the chemist himself taking control, we shall have disputes between buyers and sellers concerning the purity and strength of *"analyzed"* and other chemical products.

John B. C. Kershaw.

Price Fixing by the Idealist

To the Editor of Metallurgical & Chemical Engineering

Sir:—Among the most interesting features of the present commercial conditions growing out of the war is the question as to what constitutes a fair price, and how much profit shall be made on commodities required by the government. The problem is a perplexing one, and can never be solved to the entire satisfaction of all concerned, involving as it does so many phases of supply and demand, as well as the human frailities of greed and avarice—so that it is almost impossible to arrive at any cost figure upon which to base a fair margin of profit. This generation is witnessing a remarkable change in many things, and in the viewpoints from which things are looked at, and eventually the problem of gain will be solved just as drunkenness and autocracy are being solved by the people arriving at a decision as to what constitutes success or failure from a mundane point of view.

After all has been said and done—every man, woman, and child on earth values the good opinion of their fellows higher than anything else upon earth, and just as fast as we learn that ostentation and display are no longer sufficiently interesting to draw the homage we desire, just that fast will we solve the questions now so vexatious and trying to all of us. This war has taught us many things, and will teach us many more, and if the net result increases the happiness and contentment of man upon earth, the result will be worth all it costs. If our manufacturers and producers and middlemen can come out of this trying period chastened, and with a clean spirit, with the lesson of live and let live fully learned and digested, then we will see changes in our business morale, now regarded as chimerical.

The state must be greater than the individual, but the state can only maintain its greatness if its individual units are sound and true. So in this price-fixing we must have a frankness and honesty between

the state and the individual producer which has never been conceived of heretofore. Men are learning rapidly that beyond a certain line great wealth means more or less discontent, and that service to their fellowman is after all the most satisfying thing upon earth, whether requited or not; and now the opportunity has come to us of the U. S. A. to show that our ideals go further than being merely the richest people upon the earth. Let our great captains of industry throw open their books to the government agents; let them say we pay so much to produce this article; we need so much to maintain our plants and properly take care of ourselves and our stockholders—beyond that point our profits are the property of the U. S. A., to be used to bring about that coalition of nations, which shall from now on make the whole world a better place to live in—not for the 10 per cent on top, but for the submerged 90 per cent, who for countless generations have borne the brunt and travail of life, but whom we now see have just as much right to human happiness and security as ourselves, and let our particular line of big business see that we do our part to give it to them.

H. B. COHO.

Coming Meetings and Events

American Chemical Society, Boston, Sept. 10-15, 1917.

Third National Exposition of Chemical Industries, Grand Central Palace, New York, week of Sept. 24, 1917.

American Institute of Metals and Foundrymen's Association, Boston, week of Sept. 25 to 28, 1917.

American Electrochemical Society, autumn meeting, Pittsburgh, Oct. 3-6, 1917.

American Institute of Mining Engineers, annual meeting, St. Louis, Oct. 8-13, 1917.

CORRECTION

In the article by T. Kurahashi on "Recent Developments in the By-Product Coking Industry of Japan," Vol. XVI, June 15, 1917, page 700, the eighth paragraph should read:

"The Imperial Steel Works, the most distinguished steel and iron works in the Orient, have coke plants for the blast furnaces. They were formerly beehive ovens of the Coppee type, but are now by-product ovens of the Semet-Solvay and Koppers types."

Memoranda on Submarines

The Engineering Committee of the National Research Council issues the following data to guide those desirous of helping to circumvent the Enemy's submarine campaign by means of invention and suggestion. Any communication on the subject should be addressed to W. F. Durand, vice-chairman of the committee, at Washington.

Submarines operate singly or in groups as may seem best suited to local or special conditions.

They are supposed, where circumstances favor, to lie on the bottom at rest and with listening devices attempt to detect the approach of vessels. On receipt of evidence that a vessel is approaching, they rise to a level permitting observation with periscope, and then maneuver accordingly. When in water too deep to permit lying on bottom, the submarine must maintain steerage way in order to hold its level of submergence. The minimum speed at which this can be done will range with circumstances from 2 to 4 knots. The maximum depth of submergence is about 200 ft. The usual depth of running is from 50 to 100 ft.

They have been supposed to return to the home base at intervals of 30 to 35 days. The total radius of action will presumably range from 5000 to 8000 miles at a moderate cruising speed of 10 or 11 knots. The high speed emerged will range from 14 to 18 knots, or possibly more in latest designs. The maximum submerged speed is about 10 knots.

Hidden bases have been presumably used off the Irish and other coasts. There have aso been suspicions of bases on the coasts of Greenland and Iceland. Submerged bases for oil and supplies are used.

The time required from emergence to submergence will range from 1 to 3 or 4 minutes, according to circumstances. When submerged near the surface, the time required to raise the periscope, take a quick observation and lower it again, may range from 15 to 30 seconds. If desired, the submarine can follow an undulating path, rising and submerging alternately, at frequent intervals, at will. Or otherwise it may run fully submerged but near the surface and take frequent observation through the periscope. Modern submarines are provided with two or three periscopes. The loss or destruction of one, therefore, will not necessarily disable the boat.

Torpedoes fired from submarines are presumably aimed by changing the direction of the boat. This, however, is not assured in all cases. The torpedo, in order to run true, must travel at an immersion of about 10 ft. In smooth water it may be run at a shallower depth than in rough water.

Submarines may operate at night with less liability of detection, but with, of course, greater difficulty in picking up their target.

Submarines use the gyroscopic compass.

Sounds produced by the movement of a submarine through the water, including those traceable to the propeller, to movements of the rudder, etc., should permit of detection by the use of modern refined sound-detecting devices.

The distance at which a protecting net, plate, or shield or other means of exploding the torpedo before reaching the side of the ship must be located in order that such distance will render the effect of the torpedo harmless, will depend primarily upon (1) Weight of explosive charge, (2) Depth of torpedo when exploded, (3) Strength of the ship's structure. With modern torpedoes and a depth of 10 or 12 ft., and with the structure of modern merchant ships, distances of 20 or 30 ft. would perhaps be required in order to give good assurance against injury. With rough water and possibly much less submergence at the time of explosion, reduced distances of 15 or 20 ft. might prove sufficient. Experimental investigations on this subject show a very wide divergence among the results and no precise rule can be given. It may be added, however, that naval constructors generally are satisfied that the distance at which protecting plates or shields would have to be placed in order to secure immunity is so great as to render their use of very doubtful practicability.

Third National Exposition of Chemical Industries

Everything points to the Third National Exposition of Chemical Industries to be held at the Grand Central Palace, New York, during the week of Sept. 24th, being a much greater success than its predecessors. It will be the largest and most complete exposition of these industries ever held at any place in the world.

At the last exposition two floors of the big building were occupied by 187 exhibitors. This year three floors, possibly more, will be occupied. Already the list of exhibitors contains 250 names of companies entering every field of industry.

On Monday, Sept. 24, at 2 P. M., opening addresses will be made by Dr. Charles H. Herty, chairman of the Advisory Committee of the Exposition and editor of the Journal of Industrial and Engineering Chemistry, by Prof. Julius Stieglitz, president of the American Chemical Society, and Dr. G. W. Thompson, president of the American Institute of Chemical Engineers.

Among other speakers on the program for other days are Mr. W. S. Kies, vice-president National City Bank, who will speak upon "The Development of Export Trade with South America"; Prof. Marston Taylor Bogert, chairman Chemistry Committee, National Research Council, who will speak upon "The Operation and Work of the National Research Council for the National Weal." Dr. L. H. Baekeland of the Naval Consulting Board will make an address on "The Future of American Chemical Industry."

One day will be devoted to a symposium upon the national Resources as Opportunities for Chemical Industries, and among the speakers will be: Mr. C. H. Crawford, assistant to president of Nashville, Chattanooga & St. Louis Ry.; Mr. V. V. Kelsey, chemist-industrial agent, Carolina, Clinchfield & Ohio Ry.; Dr. E. A. Schubert, mineralogist-geologist, Norfolk & Western Railway; Dr. T. P. Maynard, mineralogist-geologist, Central of Georgia Ry. and Atlantic Coast Line Ry.; Dr. J. H. Watkins, geologist, Southern Railway.

The motion-picture program will be one of wide interest. The American Cyanamid Company and General Electric Company have already arranged to supply their films. The Bureau of Commercial Economics at Washington will supply many toward completing the range of industrial films.

Fall Meeting of American Electrochemical Society

The thirty-second general meeting of the American Electrochemical Society will be held in Pittsburgh Oct. 3 to 6. A special feature of the meeting will be a series of papers and discussions on Electrochemical War Supplies, and the part the electrochemical industry will play in the present struggle.

The committee in charge is outlining an elaborate program of technical sessions, visits to industrial plants and entertainment features. It invites the delegates to arrive in Pittsburgh on Wednesday, Oct. 2, so as to get together informally and enjoy some recreations which have been planned for them.

On Thursday, Oct. 3, a regular meeting of the society will be held in the morning, with optional excursions to industrial plants in the afternoon. In the evening an illustrated lecture on a semi-technical subject will be given.

On Friday, Oct. 4, a symposium on Electrochemical War Supplies will be held in the morning, followed by excursions to industrial plants in the afternoon. A subscription dinner will be held at the William Penn Hotel in the evening, with special entertainment features. The ladies are especially invited to be present at this function.

Saturday, Oct. 5, will be devoted to an all-day excursion, on a special train with complimentary luncheon, to several industrial plants in the Pittsburgh district.

An Opportunity for Metallurgists

Many technically trained men, beyond conscription age or otherwise, have wondered how they might now be doing their part to aid in winning our war. They have felt that a personal offer of service would only add another straw upon the shoulders of already overworked officials and bring no results, since the government could scarcely know the individual and material equipment of the man or concern making the offer. A plan is well under way at present, however, which will allow the individual engineer to use as much of his time and energy as is available in attacking problems directly connected with the war.

In the furtherance of this scheme, the national engineering societies will receive from various governmental departments a list of the unsolved engineering problems confronting them. Such of these problems as would probably fall within the scope of their individual membership will be listed and sent to each member, with the earnest request that the recipient devote as much of his time as possible to the solution of that problem nearest fitted to his knowledge, staff or plant. In this way will each engineer of this country, and there are dozens of thousands of them, be able to apply his own personal resources to the full extent of his time and inclination, knowing that his efforts will be directly contributing toward the successful prosecution of the war.

Through properly constituted committees he will also be kept constantly in touch with other engineers working on various phases of the same problem, and when success crowns their efforts, the results will be forwarded to the proper governmental department through the National Research Council.

At a meeting of the New York Section of the American Institute of Mining Engineers, held at the Machinery Club on July 20, a very clear call was sounded which should be heeded by metallurgists throughout the country. Mr. Donnell F. Hewett of the United States Geological Survey called attention to the fact that in order to produce 50,000,000 tons of steel, requiring 17 lb. of 80 per cent ferromanganese per ton, would call for the consumption of not less than 400,000 tons of this alloy, necessitating the mining, transportation and smelting of over a million tons of manganese ore; the exact amount depending, of course, upon the tenor.

Mr. Hewett further pointed out that the production of the United States could not possibly be expected to fulfill our minimum requirements, inasmuch as the whole body of developed ore is only equal to some three years' consumption. The mining of manganese has indeed been growing by leaps and bounds, even to the

extent of doubling its output annually, but unlimited expansion and intensive production are not likely owing to the nature of the known deposits—they are local enrichments in the upper few hundred feet of the earth's crust, quite local and variable in extent, geological environment, and mining methods. The best expectancy is for a small production of high-grade ore containing more than 40 per cent manganese suitable for making ferromanganese; a larger production of medium-grade ore containing 15 to 40 per cent manganese, and also a large production of low-grade ore, containing less than 15 per cent manganese, the latter two classes suitable for making spiegel. The present deficit between production and consumption is now being met by imports, largely from Brazil. The Brazilian deposits could easily tide us over the interim were we assured of adequate water transportation, which unfortunately is growing scarcer and dearer, and may even be absolutely terminated, the ships being diverted into more necessary military service.

Here is the metallurgist's opportunity. The winning of the war means the production of steel, more steel, millions of tons of steel, and each pound of steel requires a certain fraction of a pound of manganese as a deoxidizer. If, as is easily possible, this manganese may not be had at any price, the possession of unlimited iron ore, blast furnaces, steel mills and munition factories will avail us nothing, unless the metallurgist can point out some way of using our limited supply of this important element to better advantage, or develop some acceptable substitute, as was clearly pointed out in the general discussion following the formal addresses.

Good steel can be made in the crucible process without manganese. Other processes operate with heavily oxidizing conditions in the furnace laboratory, and the result is a steel containing much oxygen in solution, or as oxides, alloyed, or mechanically mixed. If poured in that condition the resulting ingot would be "red-short" and useless, cracking and breaking badly under rolling, forging or other mechanical work. The early English-made Bessemer steel had this defect, and only after much experimental work which drained his resources did the inventor discover that manganese remedied the defect. It appears, however, that the *presence* of manganese is not so important as the *absence* of oxygen and oxides. Manganese stands pre-eminent as an oxygen eliminator, not only reducing any iron oxide which it may encounter in the steel, but forming a liquid slag which washes out other mechanically entrapped oxides and separates freely from the hot metal. A certain excess not only insures good, tough steel, but also neutralizes largely the harmful effect of that omnipresent and tenacious element, sulphur.

In these two respects manganese is matchless. Silicon and aluminium metal are powerful deoxidizers, but must be added in somewhat larger quantity than manganese; further, the oxides which are formed are very infusible and tend to remain in the metal itself, forming "sonims," solid non-metallic impurities very detrimental to the tenacity, toughness and general usefulness of the resulting metal. However, it is possible to substitute silicon for perhaps 25 per cent of the manganese, the resulting manganese silicates being readily eliminated from the liquid metal.

An acceptable substitute must therefore have these properties: First, it should remove oxygen from iron compounds or solutions; second, the resulting oxides should be easily and thoroughly eliminated from the steel; third, the presence of an excess should not be detrimental to the metal.

Owing to the exacting scrutiny and slow adoption which such a substitute would undergo, a more profitable line of attack would appear to be in the direction of a better utilization of our present supplies of manganese. Two possibilities are here open: first, to get more of the manganese from the available ores into usable condition, and second, to use that manganese metal more efficiently.

Manganese ores may be regarded as mixtures of oxidized iron and manganese compounds, with more or less gangue material, often siliceous. If the ore is high in iron and low in manganese it is usually smelted in an ordinary iron blast furnace, operating very hot. The result is an iron-manganese alloy called spiegel, containing perhaps 5 per cent of carbon and 20 per cent manganese. Concentration of manganese in the blast furnace appears to be impossible, if one considers the silica which is always present. If the furnace is run too hot as much as 20 per cent of the manganese may volatilize and be lost; on the other hand, in a cooler furnace the manganese replaces the iron in the silicate slag and is wasted.

Higher manganese alloys—"ferromanganese"—are prepared in the electric furnace, which makes a standard product containing 80 per cent manganese and low in carbon. The use of this alloy is seen to be indispensable in the production of low-carbon alloys; 17 lb. of manganese as spiegel would simultaneously add 20 points (0.20 per cent) of carbon to the metal. Spiegel is rather easily made, although very wasteful of manganese. Further than that, its use is limited to higher carbon steels. Still, the bulk of American ores are so low in grade as to produce nothing else, and at the same time may be rather high in silica and phosphorus. It would seem of prime importance to develop methods in which lower grade ores might be smelted to merchantable spiegel by concentrating the manganese before smelting, and by protecting it during smelting. The next step would be to develop methods of producing ferromanganese from spiegel, for which there are a number of interesting possibilties. Or, finally, the problem of producing manganese metal by direct electrolysis of ore in solution in a bath of molten metallic salts appears to await successful solution, and the various practical limitations and operating details determined. In this matter it appears highly important for the steel producer to cease demanding either 20 per cent or 80 per cent alloys and accept intermediate analyses.

A final, most interesting possibility would obviate the addition of certain quantities of manganese by the utilization of that manganese present in ordinary pig iron, or in the steel scrap melted in the open-hearth furnace.

It is well known that carbon, while having a rather low "affinity" for oxygen at ordinary temperatures, becomes more and more voracious in its appetite for oxygen, reducing even the most refractory oxides at higher and higher temperatures. Take the case of phosphorus and carbon—at room temperatures and even up to the temperature of the puddling furnace, phosphorus has a greater affinity for oxygen than carbon, and consequently is eliminated from the bath

before any considerable quantity of the carbon. The somewhat higher temperature of the open-hearth furnace represents a region where the relative affinity of the two elements is about equal, and the phosphorous and carbon are eliminated from the bath almost simultaneously. At the yet more intense temperature prevailing in the Bessemer converter, however, the affinity of carbon has become greater than of phosphorus, and the former must be completely eliminated before any loss in the phosphorous occurs—exactly the opposite state of affairs from that which occurs in the manufacture of wrought iron.

The same thing is true of manganese. In all normal furnace operations the elimination of manganese is complete before the last of the carbon—in other words, at those temperatures manganese has a greater affinity for oxygen than carbon. But from the first, Bessemer steel has been made from pig containing so much manganese, and at so high a temperature that at the end of the carbon blow there is still enough "residual manganese" to effectually kill the melt. A modern metallurgist does not wonder that when Sir Henry Bessemer's process was first applied to English pig, low in manganese, the result was impossible. Again, the first manufacturers of basic steel were rather puzzled to find that toward the end of the heat, after all manganese had once been eliminated from the bath, test bars suddenly showed *unmistakable presence of considerable manganese.*

The explanation seems simple. The temperature has risen to such a point that the affinity for oxygen of the remaining carbon in the melt reaches and passes that of manganese, with the result that manganese is reduced from the slag and re-enters the metal.

Why is it not possible to effectually "kill" a metallic bath (if elimination of the oxygen is the prime desideratum) by a proper determination and application of the physico-chemical laws governing the relative affinity of manganese, carbon and other elements for oxygen in such a manner that a large part of this most important work may be done at a proper temperature under a slag no higher in manganese than the low-grade ores of this country and utilizing the same manganese previously eliminated from the bath with the other "impurities"?

September Meeting of American Chemical Society

War Problems to Be Discussed at Boston

The September meeting of the American Chemical Society will be held in the buildings of the Massachusetts Institute of Technology, Charles River Road, Cambridge, Mass., Sept. 11, 12 and 13, 1917. The Northeastern Section has been requested by the directors to omit the usual annual banquet and excursions, and to arrange a program characterized by simplicity and seriousness, and bearing as fully as possible on questions concerning the activities of chemists—both in the government service and in the industries during the war.

The following is a list of the chairmen of local committees:

Executive—H. P. Talbot, Massachusetts Institute of Technology, Cambridge, Mass.

Finance—A. D. Little, 93 Broad Street, Boston, Mass.

Registration—K. L. Mark, Simmons College, Brookline, Mass.

Entertainment—R. S. Williams, Mass. Inst. of Tech., Cambridge, Mass.

Press and Publicity—R. W. Neff, 22 India Square, Boston, Mass.

Entertainment of Ladies—Mrs. A. D. Little.

Registration will be conducted at the buildings of the Massachusetts Institute of Technology, Cambridge, except on Monday, Sept. 10, when it will be held at the Hotel Lenox.

Society headquarters will be at the Hotel Lenox at the corner of Boylston and Exeter Streets.

The use of the Engineers' Club, at the corner of Arlington Street and Commonwealth Avenue, will be extended to all members of the Society.

GENERAL PROGRAM

Monday, September 10

4.00 p. m.—Council Meeting. Engineers' Club.

7.00 p. m.—Dinner to the Council at the Engineers' Club (tendered by the Northeastern Section).

Tuesday, September 11

10.00 a. m.—General Meeting of the Society in the Massachusetts Institute of Technology.

Address of Welcome:

Dr. R. C. Maclaurin, President Massachusetts Institute of Technology.

Response:

Julius Stieglitz, President Americal Chemical Society.

General Papers.

2.00 p. m.—General Conference on Chemistry and Chemistry in Warfare, opened by William H. Nichols, Chairman Committee on Chemicals, Council of National Defense. Marston T. Bogert, Chairman Chemistry Committee, National Research Council.

5.00 p. m.—Harbor trip to Hotel Pemberton, where an informal shore dinner and smoker will be held.

Wednesday, September 12

Morning.—Conferences of Divisions.

Afternoon.—Divisional Meetings.

Evening.—President's Address, Huntington Hall, Rogers Building, Massachusetts Institute of Technology, Boylston Street.

Thursday, September 13

Morning and Afternoon.—Divisional Meetings.

The Metallurgy of Lead Ores in the Lower Mississippi Valley[1]

By Herman Garlichs, E. M.

The first metallurgists in Missouri were the Indian and the hunter. The early settler learned to procure his bullets either by melting ore in his camp fire or by throwing pieces of galena on an old stump and depending on the usual roasting and reaction method to obtain the metal.

Various other older practices may be passed over lightly, as many of them are now practically abandoned. The earliest smelting furnace was the log hearth, which was followed by the "ash" furnace, the English reverberatory, the Backwoods and water-backed hearth.

[1]An abstract of a paper to be presented at the St. Louis Meeting of the American Institute of Mining Engineers, October, 1917.

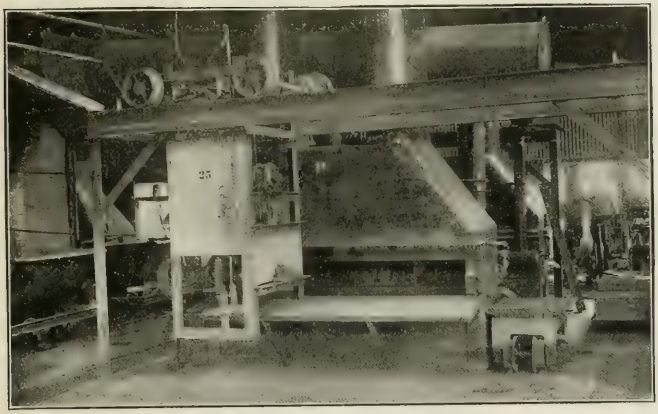

FIG. 1—RABBLING MACHINE AT BEGINNING OF TRIP

Much information regarding these processes may be obtained from *Missouri Geological Survey*, Volume VI; *Illinois Geological Survey, Bulletin* 21; and Pulsifer: *Notes for a History of Lead.*

The reverberatory and hearth methods require pure ores. On this class of ores these processes give fair results when care is taken in smelting. The yield ranges from 80 to 90 per cent of the lead in the ores, allowing no recovery in fume. The blast furnace preceded by roasting in reverberatory is adapted to ores that are less rich in lead, and contain impurities which would cause severe losses if treated by any other process. Also, when there is a large amount of ore to be treated, with scarcity of labor, the blast-furnace process is the more economical.

ANALYSES OF ORES AS MINED IN SOUTHEAST MISSOURI, AND OF VARIOUS GRADES OF RESULTING CONCENTRATES

	Ag. %	Cu. %	Pb. %	SiO_2, %	Fe, %	Al_2O_3, %	CaO, %	MgO, %	Zn, %	S, %	Ni and Co, %
Ore	0.12	0.06	5.7	5.0	4.1	4.9	25.5	14.2	0.8	2.0	...
High-grade concentrates	0.7	0.13	73.2	1.0	3.5	..	2.6	0.8	0.4	15.0	0.05
Medium concentrates	1.3	0.12	68.6	1.4	4.6	..	3.1	1.4	0.8	15.5	0.06
Low-grade concentrates	1.0	0.30	65.8	0.5	3.1	0.5	4.3	2.8	1.7	13.7	...
Flotation slimes	...	0.50	45.0	9.6	4.4	3.1	7.5	4.2	4.0	12.3	...
Flotation slimes High-grade	3.7	0.05	57.8	6.0	2.7	..	2.2	1.4	9.4	15.5	...
Joplin concentrates	...	...	80.2	1.1	1.0	..	0.4	..	1.7	13.3	...

Analyses of the ores as mined in southeast Missouri—which are about the average of the district—also analyses of various grades of resulting concentrates, show that the metallurgy is simple, the removal of the sulphur and the slagging of the dolomite in the blast furnace being of prime importance.

The big improvements which have revolutionized the metallurgy of the Mississippi Valley ores in the last 10 or 12 years are:

1. The introduction of Hunting-ton-Heberlein pot roasting, preceded by a preliminary roast in a mechanical furnace (Godfrey), subsequently smelting in the blast furnace and filtering all fumes through cotton or woolen bags.

2. The introduction of the Dwight-Lloyd sintering process, which eliminated preliminary roasting of the concentrates (but not of the mattes), with subsequent smelting in blast furnace with bag-houses attached.

At Herculaneum, the Godfrey pre-roasting furnaces were abandoned in the Huntington-Heberlein process, and the Wedge roaster was adopted for the pre-roasting of mattes. Later it became apparent that the elimination of sulphur was still unsatisfactory, and that there was an undesirable but necessary dilution of the concentrates from 70 to 65 per cent lead to 40 and 45 per cent to render the Dwight-Lloyd machine applicable with a single roast.

To avoid these objections, the double roast is being installed by both the Herculaneum plant of the St. Joseph Lead Co. in Missouri, and the Federal plant of the Federal Lead Co. in Illinois. A rapid preliminary roast is given on a separate line of Dwight-Lloyd machines, and this pre-roasted material is then turned over to another set of Dwight-Lloyd machines (Herculaneum), or to Huntington-Heberlein pots (Federal) to reduce the sulphur of the finished product to about 2 to 2½ per cent, and with its lead contents increased to 50 or 55 per cent.

It is expected that the double roast will effect the following improvements over present methods:

1. To avoid the large production of mattes which lock up lead and require expensive re-treatment for its recovery.

2. To avoid diluting a 65 to 70 per cent lead concentrate to 40 to 45 per cent, which means large additions of barren fluxes.

3. To utilize to the fullest extent the fluxing values in the ores. This means that no limestone should be added

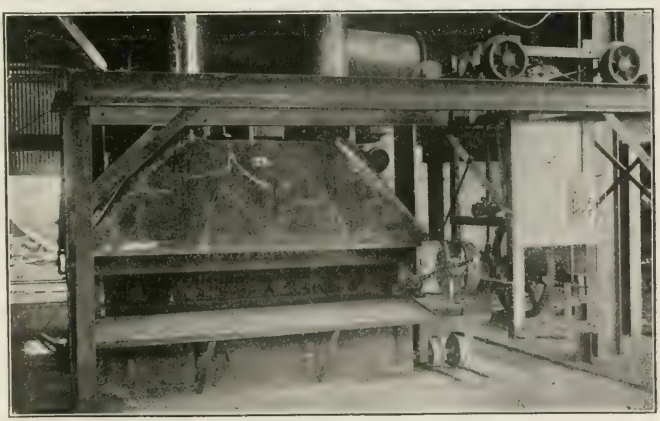

FIG. 2—RABBLING MACHINE AT END OF TRIP

to a blast-furnace charge, while some silica and iron will be required. The resulting blast-furnace slags will contain from 6 to 7 per cent MgO, with a corresponding increase in blast-furnace capacity for original concentrates.

4. To recover a part of the copper in the concentrates, which metal is at present mostly oxidized and lost in the large amount of slags made.

The other important improvement in the metallurgy of Mississippi Valley lead ores was the mechanically rabbled hearth, known as the "St. Louis hearth." This machine was developed at the Collinsville plant of the St. Louis Smelting & Refining Co., and has been fully described by W. E. Newnam.[2]

The St. Louis hearth, which is illustrated in Figs. 1 and 2, is applicable only to concentrates assaying 68 per cent or more in lead, and therein differs from the Huntington-Heberlein and Dwight-Lloyd methods, which treat concentrates of varying grades.

When concentrates assay over 70 per cent it is considered that the hearth shows better recovery in lead, and is the most economical method, although the double roast, when perfected, promises to be equally as cheap as to cost, with the advantage of being able to treat all grades of concentrates.

The peculiar advantages of the mechanical hearth for the higher grade concentrates are:

1. It treats the concentrates undiluted with any flux.

2. It is a very efficient desulphurizer, expelling 95 per cent of the sulphur.

3. It retreats all the dust and fume produced, leaving the gray slag as the only product to be sent to the blast furnace, with a large reduction in slag and matte produced.

4. The hearth makes a total extraction of 82 to 84 per cent of the lead contained in 70 per cent concentrates. With concentrates assaying 75 to 80 per cent in lead, 90 to 95 per cent represents the total extraction, leaving from 5 to 10 per cent of lead contents in the gray slag. This practically eliminates any retreatment of mattes.

The mechanical rabbling machine is limited to 68 per cent lead concentrates, and for this reason, where lower grades of concentrates are received at Collinsville, the Dwight-Lloyd machine must be used as an auxiliary. All mattes produced by smelting the gray slag of the hearths and the Dwight-Lloyd sinter at Collinsville can be easily handled *raw* on the Dwight-Lloyd, so that a Wedge roaster is not needed for pre-roasting.

The St. Joseph Lead Co. is erecting at Herculaneum 12 St. Louis hearths to be used in connection with the double-roast process for the treatment of any excess of high-grade concentrates.

In the southeast district, about 75 per cent of the output of the mills is a high-grade product, applicable to hearth work, the remainder being lower-grade concentrates and flotation slimes. In order to sweeten the mixture for the double roast (*i.e.* to raise its grade) it is necessary to use a certain proportion of the high-grade concentrates for this purpose. The balance of the concentrates should be worked by the mechanical hearth to obtain the most economical results both as to cost and recovery.

[2]See Transactions, American Institute of Mining Engineers, 1916, Vol. 54, p. 485, or Metallurgical and Chemical Engineering, Vol. XIII, Dec. 15, 1915, page 974.

The lead produced from Missouri ores contains very few impurities, and when subjected to a single liquation process can be used for all purposes except corroding. A typical analysis of Missouri undesilverized lead is as follows:

Ag, 0.0080 (2.4 oz. per ton); As, trace; Sb, 0.0030; Bi, trace; Cu, 0.0800; Fe, 0.0015; Zn, trace; Ni and Co, 0.0080; lead by difference, 99.8995.

The Herculaneum and Collinsville plants desilverize part of their lead, recovering about 1 to 2 oz. of silver per ton, and producing an unusually pure lead for the manufacture of white lead and other purposes requiring a very pure lead.

The following analysis of southeast Missouri "refined" indicates the unusual character of Missouri desilverized lead:

Ag, 0.005; As, trace; Sb, 0.0020; Bi, trace; Cu, 0.0002; Fe, 0.0004; Zinc, 0.0004; Lead by difference, 99.9965.

The difference between southeastern Missouri and western refined lead is almost entirely due to bismuth (about 0.05 in Western refined) from which the Missouri ores are singularly free.

The refining of the Missouri crude lead for corroding purposes follows the usual practice, except that no softening furnaces are necessary.

At Collinsville the lead from the blast furnace is poured molten into the drossing kettle. After carefully drossing to eliminate as much copper as possible, it is pumped into a desilverizing kettle. The hearth lead is charged as pig directly into the desilverizing kettle, drossed, and desilverized. Zinc is added, stirred in, and the zinc-silver-lead alloy (crust) is removed. This first crust is reworked in succeeding kettle charges until sufficiently high in silver to be set aside. The resulting retort bullion (lead riches) assays from 500 to 600 oz. Ag per ton, and represents a concentration of the silver contents of 250 to 300 tons of lead into 1 ton of retort bullion. The zinc consumption per ton of refined lead produced is about the same in amount as is consumed in refining argentiferous bullion. Special attention must be given to removing as much copper as possible from the lead to be desilverized.

The quantity of zinc-silver-lead alloy made is insufficient in quantity to warrant the operations of retort and cupels, and heretofore the alloy has been sent to some outside refinery to be separately distilled in retorts, and returns are based on the sampling of the various products obtained, such as retort bullion, dross, spelter, and blue powder. The assay results check quite closely. Retorts and cupels are being installed at Collinsville so as to be able to treat the alloy whenever occasion demands.

St. Louis, Mo.

The Composition of Shell Steel

By Reginald Trautschold, M.E.

The steel used for the manufacture of shells must possess certain physical properties, and with the object in view of assuring such properties the various governments have adopted specifications covering the allowable chemical composition of the stock used. Certain variations must, perforce, be permissible—the chemical "tolerance." The steels universally used may be classified as carbon steels, to which certain other chemical elements are added for improving the quality of the steel and in which there must necessarily be a trace

of other elements which may not be exactly desirable, but cannot be avoided in commercial production.

The object of the chemical specifications is to secure a metal possessing the requisite physical properties, for the strains to which a shell is subjected are all physical, and the efficiency of the shell—its destructive capabilities—is governed not by chemical but by physical properties. Particularly are the physical properties of the steels important in high-explosive shells which are shattered by the charge confined within the projectile. In the case of shrapnel, the properties of the steel are not so important, the main requisite for them being a sufficient tenacity for the projectile to remain intact until moment of "breaking," i. e., the moment of ejection of the shrapnel balls.

The English specifications for high-explosive shell steels are probably the most exacting of any, but those imposed by the United States are sufficiently exacting to prohibit the use of much otherwise available and excellent steel stock. Apart from the iron content, the percentages of chemical elements which may occur in high-explosive shell steel are given in Table 1. With the exception of manganeese, only the maximum allowable percentages are given, so there would seem to be quite a permissible variation in composition. Nevertheless, the allowable percentage of certain elements is so small that exacting mixtures of metal are essential, whether the open-hearth or the converter process is employed in the production of the steel. The specifications of other governments differ somewhat, but the variations cited may be taken as typical of what is generally considered good and necessary practice.

Compared with such requirements, then, the chemical properties of the steel used by the Germans are of particular interest. For, as it must be admitted that the "art" of war has been developed to a high point by this nation, it is altogether probable that the manufacture of shells has been given most careful attention and developed to a high degree of perfection.

TABLE 1

United States Specifications

	Minimum Per Cent	Maximum Per Cent		Minimum Per Cent	Maximum Per Cent
Carbon		0.55	Phosphorus		0.04
Manganese	0.40	1.00	Copper		0.10
Silicon		0.30	Nickel		0.50
Sulphur		0.04			

During the first year of this great war, a number of fragments of the German high-explosive shells which caused such damage in Belgium and France were collected and carefully analyzed in England. These shell pieces were not selected samples, but fragments picked up on battlefields and were presumably parts of projec-

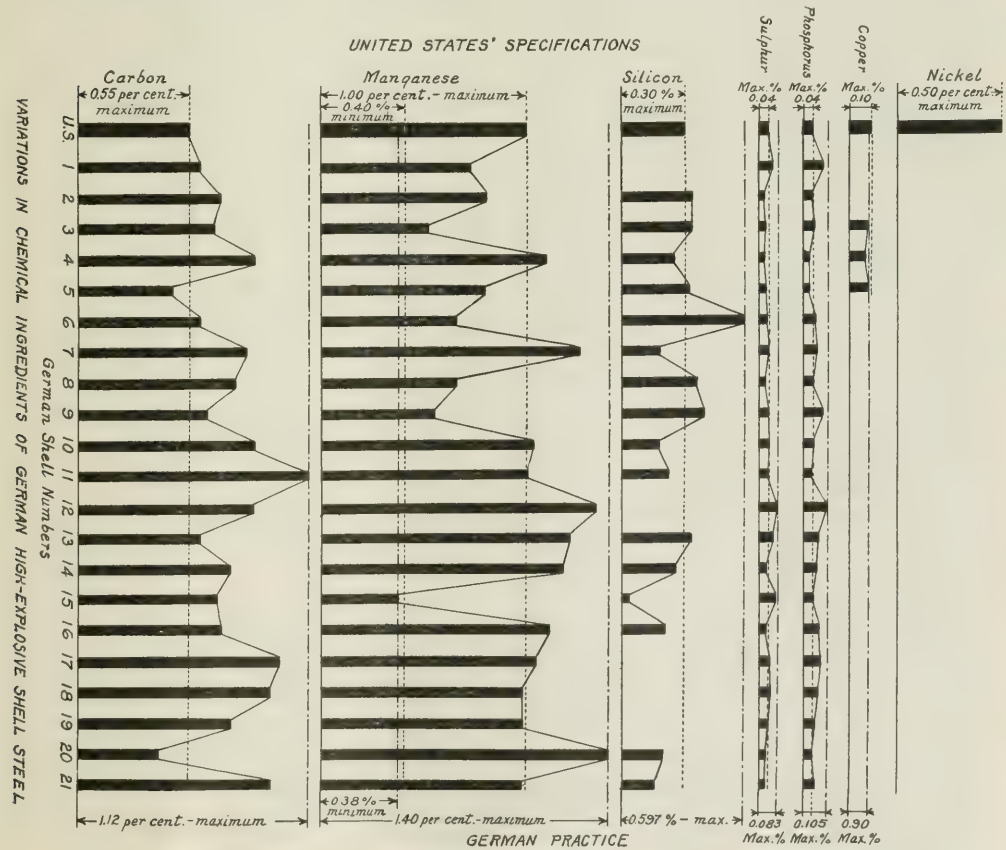

FIG. 1—GRAPHICAL COMPARISON OF UNITED STATES AND GERMAN HIGH-EXPLOSIVE SHELL STEELS

tiles made before the outbreak of the war—projectiles upon the deadly success of which hope of the subjection of Europe, if not of the world, had been based. That is, the fragments collected were unquestionably pieces of the most perfect and most destructive shells the Germans had been able to manufacture at a time when they were in position to obtain any quality of steel they might deem desirable for shell production. This is an important point, for fragments of shells picked up more recently might be of composition which the Teutons had been compelled to adopt by reason of inability to secure metal of better grade. The analysis of the collected samples, which was published by Dr. J. E. Stead in "The Engineer," probably, therefore, depicts the best German practice.

The proportion of the various elements, exclusive of the iron, found in twenty-one of these high-explosive shell-fragments is plotted in Fig. 1. Comparing the chemical composition of these German shells with corresponding allowable percentages in the United States specifications, it will be noted that *not one* German shell would have passed our requirements. Yet every one of these shells was a highly efficient destructive missile.

In the case of carbon content, which, according to our specifications, is limited to 0.55 per cent, there were only two of these tested shells which did not exceed this maximum: in one case the excess was over 100 per cent, while the average excess was 28 per cent.

The manganese content, upon which both a maximum and minimum allowable percentage is fixed in our specifications, does not vary so greatly between German and American practice. Only one of the German shells showed less manganese than our minimum allowance of 0.40 per cent, and this difference was so very slight as to indicate that opinion is pretty well agreed as to the minimum amount of manganese which high-explosive shell steel should contain. About half the German shells equaled or exceeded our allowable maximum of 1 per cent manganese, indicating that our enemies consider the addition of manganese a greater advantage than do our steel experts.

In the case of silicon, when this element is present in German shells, the amount does not differ greatly from our practice, although in one case the German shell contained nearly 100 per cent more than allowable United States maximum. In one quarter of the analyzed shell fragments, however, little or no silicon was found, so it is evidence that this element is not considered so essential in the manufacture of high-explosive shell steel that it need be added to the basic Bessemer steel which doubtless furnished the stock, while, at the same time, an excess of such element seems not to be considered detrimental.

The presence of sulphur and phosphorus is the cause of eliminating much of our steel for high-explosive shell production, but such seems not to be the case in Teutonic manufacture. Although the Germans seem to strive for low percentages of these ingredients they do not reject steel running even some 100 per cent to 150 per cent higher in these ingredients than would be permitted in steel for American explosive shells.

In the few German shells which showed any trace of copper, the content would have been allowable in American practice, but quite evidently the presence of this element is not considered of any particular advantage, for by far the larger majority of the shell fragments showed no trace of it.

In the case of nickel, which may be present according to American specifications in the proportion not exceeding 0.50 per cent, no trace was found in any of the analyzed shells. This would seem to show that the addition of nickel is not considered indispensable by them.

Table 2 gives the allowable chemical variations which would be permitted by the Germans, basing the percentages upon the twenty-one typical shells which were carefully analyzed. The establishment of definite specifications on twenty-one analyses could not, of course, be taken as conclusive evidence that the variations shown may not be exceeded, but, as there is no reason to assume that the fragments examined were other than typical, such specifications may be safely taken as acceptable to the war lords. These allowances may be more exacting than those permitted by the German government, but they are certainly not more liberal.

Table 2

Probable German Specifications

	Minimum Per Cent	Average Per Cent	Maximum Per Cent
Carbon	0.40	0.75	1.12
Manganese	0.40	0.93	1.40
Silicon	0.00	0.28	0.60
Sulphur	0.00	0.05	0.085
Phosphorus	0.00	0.06	0.105
Copper	0.00	...	1.00

Should some such specifications as these be adopted by our Government, it would make available a considerable tonnage of steel which to-day cannot be used in the production of high-explosive shells. With a larger steel supply available, the production of shells could be greatly accelerated. There is no question that shells could be produced in this country quite equal to those made in Germany—a quality of shell which heretofore has proved quite efficient.

The wide variations in the composition of German high-explosive shell steel indicate that not only are no exact chemical requirements imposed, but also indicate the strong probability that the requirements for acceptable shell steel are not based on chemical but upon physical properties. This theory is indorsed to some extent by the French who lay particular stress on exhaustive and reliable physical tests while imposing little limitation as to chemical composition.

The chemical composition of steel can only be taken as indicating what its physical properties *may* be. It cannot be accepted as a definite indication, and for this reason all governments require confirmatory physical tests. It would seem the part of wisdom, therefore, to rely more on physical tests and impose less strenuous chemical requirements.

A shell possessing the requisite physical properties must be satisfactory from the point of view of destructiveness, irrespective of its chemical composition. Some such reliable test as the hydraulic test required by the French government for its high-explosive shells would appear to be the prime necessity. This test may be easily made and would automatically establish sane chemical requirements. Similar practice on the part of our Government would accelerate production, cheapen cost of manufacture and make available much steel which is at present barred by specification.

New York City.

Chemical Engineering Aspect of Renovating a Sulphide Mill*

By Hugh K. Moore

In the winter of 1909 and 1910 I was called to La Tuque, P. Q., Canada, in order to render what services I was able in renovating and reconstructing a pulp mill running on the so-called sulphate process. The word sulphate is a misnomer and I have always objected to the term, which even though accepted in the trade as descriptive of the process, really is not descripive of the process by which the pulp is made. As you all know, the so-called sulphate process is so named from the large use of sulphate of soda as a raw material. This sulphate of soda, however, is not used directly in cooking, as it is reduced beforehand to sodium sulphide, sodium hydrosulphide, caustic soda and carbonate of soda. The essential difference between this process and the soda process is the sulphide content of the cooking liquor. The name sulphide then is descriptive of this particular process of making pulp and is as correct as "soda" and "sulphite," names which clearly designate the other well-known processes by which pulp is made.

Now I wish to say, lest you expect too much, that when I went to La Tuque I did not know what a sulphate mill was and understood nothing about the process; and, furthermore, I was called upon so suddenly that I had not time to inform myself as to the nature of the process before I started.

Before going into details as regards the processes and innovations a few remarks on the scope and limitations of this article may not be out of place. In the first place, this being about one particular mill instead of several mills, I purposely suppress all data on costs, maintenance, repairs, etc., neither shall I give any data as to yield per cord of wood, or salt cake, fuel, labor, repairs, etc., etc., per ton of pulp. Neither shall I give any figures on any of the installation costs. In stating the facts and methods of overcoming the difficulties I want it to be particularly understood that I am not claiming credit for all the different changes made. Many of these I made, but many were made by Mr. Brown, Mr. Lovett and others, many were combinations of ideas of all, and it would puzzle a Philadelphia lawyer to assign to whom credit for certain of these changes should be given. The idea in mind is not to assign credit to any one person or group of persons, but to show how a knotty problem was tackled and solved.

RÉSUMÉ OF SO-CALLED SULPHATE PROCESS

In order that those who have no more knowledge of the workings of the sulphide process than I had at the start (if there be any such) may have an understanding of the difficulties encountered, I think I had better give a short résumé of what the sulphide process is.

Woods of the conifer type are mechanically partitioned to form chips about ¾ in. square and ⅛ in. thick through a chipper, and these are run into a digester. After the digester has the required amount of chips the cooking liquid or alkali is run in, the digester is closed and heated by live steam, keeping the pressure on top of the digester during the cooking at 90-100 lb., relieving the excess of liquor and steam which are separated in a separator and blowing the steam into water to heat it so that it can be used in washing the pulp. When the digester is cooked it is connected with tanks and blown. The steam is blown off through vomit stacks, the liquor drained through false bottoms and the pulp washed according to the principles of systematic counter-current extraction. Now, owing to the propensities of this liquor for foaming the ordinary evaporator was not thought available so the liquor was passed through a disk evaporator, the source of heat being the waste gases from the steam boilers. The disk evaporator in brief is made of hundreds of pieces of iron plates set around a revolving shaft. As these disks revolve they dip into the liquor, then emerge from the liquor with a film of liquor thereon. The hot waste gases from boilers pass over these films evaporating the water. By having several of these in series and enough waste heat you can progressively concentrate the liquor. After passing through the disk evaporators heated by furnace gases the partially concentrated liquor passes another set of disk evaporators heated by gases from the incinerator. By this means it is possible to concentrate the liquor to 20 deg. Bé., where mechanical troubles place a limit to this method of concentration. From the disk evaporator it runs to an incinerator which is simply a brick-lined rotary furnace. The remainder of the liquor is evaporated and the residue charred so that it comes out as black ash which runs from the end of the incinerator on to the floor. The source of heat is the white-hot gases from the smelting furnace. This black ash is then shoveled over, sulphate of soda added thereto and thoroughly mixed therewith. Wood is now thrown into the smelting furnace and this black ash shoveled on top of the wood. Air from a positive blower is injected about 15-20 in. from the bottom of the furnace and the black ash burned, reducing part of the sulphate of soda to sulphide of soda according to the following equations:

$$Na_2SO_4 + 4C = Na_2S + 4CO.$$
$$Na_2SO_4 + 2C = Na_2S + 2CO_2.$$

Also part is reduced to carbonate of soda with small amounts of caustic soda and sulphate of soda passing through unchanged. The soda content in the black liquor is mostly reduced to carbonate of soda though part is also reduced to sulphide of soda. The molten alkali liquor runs from a spout into a dissolving tank in which is an agitator, while the hot gases pass through the incinerator charring the carbonaceous residue, making black ash in the front part of the incinerator and evaporating water in the further end of the incinerator, thence going through the disk evaporators and out of flue as above described.

This liquor in the dissolving tank is pumped to the alkali room, where it is tested and the requisite amount of lime is added whereby the sodium carbonate is converted to caustic soda. This is decanted by allowing the calcium carbonate to settle and withdrawing the supernatant liquor by means of a siphon. The first two washings are added together while the weak liquor of the last washings are pumped to the dissolving tank, and this constitutes the liquor in the dissolving tank into which the molten alkali runs as above stated. The strong washings constitute the cooking liquor for the digester, though some strong black liquor may be added as a diluent.

*A paper read at the Ninth Semi-annual Meeting of the American Institute of Chemical Engineers, Buffalo, N. Y., June 21, 1917.

This, in brief, is a description of the chemical end of the sulphide process.

DRAWBACKS OF PROCESS

Now let us consider what is wrong about the above process from the standpoint of a chemical engineer.

The process being a cyclic one, it obviously makes no difference at which point we start so long as we complete the cycle. Accordingly, I shall start with the evaporation of the liquid.

(1) From the above it will be seen that the process described is one of direct evaporation, the only good reason for the same being the difficulty of accomplishing it by multiple-effect evaporation. It will be noticed that there is a consumption of wood in addition to the heat evolved from the solids of the liquor itself. This consumption of wood I wish to state is in order to get over *mechanical* difficulties rather than an absolute necessity. The consumption of wood is small in amount and is well paid for in the increased production and saving of labor. Even if the sources of heat for evaporation were entirely waste heat, *i.e.*, heat which cannot be recovered and used in other parts of the mill, there is still a sound basis for putting in a multiple effect system, and those who argue to the contrary have an incomplete understanding of the problem involved. Suffice to say for the present that for every pound of solid matter in this liquor there are 5000 B.t.u., which is sufficient not only to do its evaporation but furnish heat to *eliminate the wood bill* and materially reduce the amount of coal consumed in the boilers.

(2) The disk evaporators get out of order and are a constant source of expense. The liquor has a tendency to polymerize and this clogs the disk evaporators. This polymerization is due to the hot flames through which it passes, not its concentration.

(3) The variations in the original strength of the black liquor are passed right on to the incinerators, which are unable to take care of these variations.

(4) The incinerators have a habit of "ringing up" in the inside, one side of the ring having molten alkali, the other side of the ring having black liquor. Now when this ring breaks the liquor runs on top of the molten alkali and an explosion follows. If this ring is located near the end the chances are that one or more men go to the hospital for burns, and the fear of things like this happening tends to prevent the keeping of men long enough in this department for them to become expert.

(5) The unevenness of the fire in the smelting furnace can only have one result, viz., the rapid deterioration of the furnace, not only from expansion and contraction, but also from the stuffing action of the sodium sulphide sublimed with sodium carbonate followed by the oxidizing action of the air under these intermittent conditions of running.

(6) The fine particles of salt cake and alkali are carried from the furnace through the incinerator and disk evaporators and lost with the exit gases.

(7) The separation of the carbonate of lime in the causticizing room takes a very large equipment and is troublesome in the extreme if the liquor happens to contain even a small per cent of iron sulphide. It usually takes six hours to settle a tank once and the heat lost is considerable of an item. The chances of losing alkali in the sludge are considerable, either through accident or neglect of duty.

(8) The sludge, which has a value in itself, is lost and may be treated for lime if so desired.

(9) There is also the possibility of the lime getting into the pulp through careless siphoning here.

(10) The steam, which is separated from the relief of the digesters being blown directly into the water which washes the pulp, blows many impurities therein, which gives the pulp, and consequently the paper made therefrom, an odor which prevents it being used for some purposes; for example, flour bags.

(11) This relief contains somewhat over 200 gal. of turpentine a day which is equal in quality to the best gum turpentine. By the above method all this turpentine is lost.

(12) Now taking up the process of blowing the digester we find that a considerable amount of pulp is blown through the vomit stack and lost.

(13) Every digester blown discharges 18,000 lb. of steam into the atmosphere, the heat of which might be advantageously recovered and used in the mill.

(14) When we come to the washing of the pulp we find the process slow and cumbersome. A process full of inherent difficulties of clogging, which either means a check in production or a waste of alkali. Both of these usually occur.

(15) An appreciable amount of pulp is carried away in the digester liquor.

METHODS OF OVERCOMING DRAWBACKS

Having pointed out the objectionable features of the process as ordinarily carried out, let us consider the methods by which they were overcome and the experiments relating thereto.

EVAPORATION

As before stated, this black liquor is very cantankerous, foaming under the least provocation. Bearing this in mind we built a multiple effect evaporator specially designed to overcome this fault. At first we could not run it at anywhere near its theoretical capacity on account of the foaming propensities of the liquor. Among the experiments we tried was to run the foam and steam through a specially designed centrifugal steam separator run at a very high velocity by a direct-connected steam turbine, the object being to throw the separated liquor through periphery, letting the steam pass through the center to the next effect. This worked very well when the bubbles of foam were large, but when they were small and consequently compact and heavy there was not enough power in the turbine to carry on this increased amount of work. Neither was it advisable to make larger turbines because the power required was so great that the steam consumption would be so great that most of it would have to be wasted as only a small portion could be used in the evaporators.

We finally carried the liquor only about 1½ to 2 in. in the tubes in the first effect, 6 in. in the second effect, and increasing heights as the concentration proceeded. The principle of this objection was that foam was constituted of a globule of steam surrounded by a heavy film of liquor, and that if we could produce the foam and evaporate off the water in the film to make it break we should accomplish our purpose. Now the height at which the liquor stands in the tube limits the quantity of the resulting foam, other conditions, such as steam pressure density, etc., etc., being equal. Now this foam shooting up through the remainder of the hot tubes has

its films transformed into steam, so that there is so much steam and so little film that they readily separate the steam passing to the next effect and the liquor is returned to where it finds its way to the next effect. Care, however, must be taken that too much of the foam shall not be evaporated as gumming up of the tubes results. The levels were for a time maintained by specially designed floats and this was continued until the men got so expert that they were no longer necessary. Large separators were put between each effect to catch any occasional foam and return it to its proper effect. A solenoid was installed which could be regulated so as to return any liquor having over a predetermined strength, and this could be regulated with the greatest nicety. Owing to the mercaptans given off in the liquor which have a very corrosive action we found that we had to redesign many parts of the vacuum pump and substitute rubber rings for the cast-iron piston rings. We got rid of the calcium sulphate which precipitated on tubes by surrounding the tubes with water and putting an acetylene flame down through the tubes, thereby heating the calcium sulphate and cracking it off without overheating the tubes. What with redesigning condensers and other apparatus we finally evolved an evaporator of six effects capable of evaporating considerably over 4,000,000 lb. of liquor a day to a consistency of from 33 deg.-35 deg. Bé., and we have now obtained a uniform liquor. These multiple-effect evaporators made the disk evaporators obsolete and they were scrapped and all the resulting repairs, labor and shutdowns eliminated.

ELIMINATION OF INCINERATOR AND EXPERIMENTS RELATING THERETO

Now, having obtained a uniform concentrated liquor, we are in a position to start work on the elimination of the incinerator. In order to do this several preliminary experiments became necessary which at first sight may seem to have no connection therewith. Previous experiments had shown that iron would not stand either the alkali liquor or the alkali gases under the usual conditions. Experiments were now conducted to see if it would withstand these if kept at temperatures not exceeding 400 deg. Fahr. The preliminary experiments seemed to show that it would, so we then obtained a steam boiler, erected it and built a smelting furnace in front of it, passing gases under the boiler and through the tubes just as if we were burning coal. Before starting we had an inspector from the Hartford Insurance Company go over the boiler and test it thoroughly. We then operated this boiler under 100 lb. pressure for about a year under these conditions, and had a reinspection by the same man and found that it had not deteriorated under these conditions any more than the corresponding deteriorations of a boiler running with the ordinary coal fire. Of course, we had trouble with salt cake subliming and vaporizing and condensing on the boiler and fouling the tubes, but we at this time were not interested so much in this aspect of the case as we were in ascertaining if the boiler would stand up under these conditions.

Having satisfied ourselves absolutely that the boiler would stand up, we next tackled the problem of burning the liquor in the furnace in order to save the heat in the boiler.

Now a few words as to the nature of the residue obtained from evaporating the water from the black liquor. This is a dark-brown plaster or semisolid, according to the temperature. At temperatures of steam it melts forming a sticky, gummy mass, impossible to handle in any known manner. Even in the cold it cannot be chipped, disintegrated, handled or conveyed in any known manner, and two lumps placed one on the other will nevertheless coalesce into one another. It is a most difficult substance to handle. It was thought that if this could be absorbed in sawdust, that we could evaporate the water with furnace gases. We put in a drying tower composed of shelves, blowing the sawdust alternately in and out from shelf to shelf, running the black liquor thereon and passing the flue gases over it from bottom to top. The dried, impregnated sawdust was then carried by conveyors to the furnaces. This worked as long as there was sawdust enough from the sawmill. But there was never sawdust for more than 20 per cent capacity. We then tried hogging wood, but this got us into trouble at once, and it was found that owing to the low absorptive capacity of the hogged wood that it was impossible to build a drying tower strong enough to deal with the resultant sticky mass. We went from 6-in. I-beams to 15-in. I-beams, but found we would twist off the latter almost as rapidly as the former. We even tried using black ash as an absorbent for the black liquor. When it worked the reduction in the furnace was excellent, though it was found the resulting amount of iron in the liquor produced made the problem of settling out of the lime sludge a very difficult one. However, owing to mechanical troubles, this was found, as above stated, absolutely impracticable and had to be abandoned.

We had some time previously tried to atomize this liquid into a hot flame, hoping to evaporate the water from it and have it charred by the time it landed 7 ft. away, but without success, and the reason is very clear, if one considers the difficulty of getting a fine spray with this liquor.

A simple calculation will show that for the evaporation of the water alone, say nothing of charring, the diameter of these droplets could not be over 0.0029 in. if evaporated in gases at 2000 deg. Fahr. traveling a distance of 7 ft., heat abstracted from gases 0.005 in. thickness surrounding the droplets during the entire passage through the furnace, liquor 50 per cent water and temperature 210 deg.

Now, as a matter of fact, this liquor cannot be atomized to this fineness or anywhere near it, so though we started with a good fire we soon put it out by plastering it over with this liquor.

Now, after this drying tower proved such a failure, our minds turned back to our atomizing experiments. If we could only atomize finer and get some additional heat, we figured that it ought to be done this way. There was some chance that by experimenting we might make an improvement in atomization, and it occurred to us that the additional heat might be obtained from radiation. Stefan's law naturally occurred to our minds at this stage of the proceedings, and we at once collected all the data relating thereto to see if we could make a practicable use of the same.

This law is in brief that the heat radiated from one black body to another varies directly as the difference of the fourth powers of the absolute temperature. This may be expressed as follows:

$E = K(T_2^4 - T_1^4)$ where E is the total energy radiated and K a constant, T_2 and T_1 being absolute temperatures, of which T_2 is the higher.

It is not our intention in this paper to drag it out to an interminable length by going into the mathematics of this law, which have been so well established that any one interested may refer to the reference given at the end of this paper.

We have, however, calculated certain results and submit these in the forms, viz., the tabulated and the graphical chart. The calculations finally reduce down to the following simple formula:

B.t.u. per sq. ft. per min. $= 2.66 \times 10^{11} (T_2^4 - T_1^4)$.

CALCULATIONS
ASSUMING STEFAN'S LAW FOR BLACK BODIES
English Units $K = 2.66 \times 10^{11}$ B.T.U. per min. per sq. ft.
B.T.U. $= K(T_2^4 - T_1^4)$

In order that there may be no mistake as to what radiant heat is I will state that it is the heat which passes from a body of higher temperatures to a body of lower temperature through an intervening gas without heating that gas. Thus the heat of the sun heats the earth without heating the intervening air. The earth in turn heats the air. The so-called steam radiator heats by convection, not by radiation. It must be borne in mind that this is not a simple process of evaporation and that this is not the main object in view. The main object in view is the recovery of the alkali present in the digester liquor and that this must be a reducing process.

This liquor after the water has been evaporated analyzes 45 per cent ash and 55 per cent combustible, which is spoken of in the paper as lignin, though it contains sugars as well as lignin, the approximate formula for which being $C_{15}H_{22}O_{11}$. This so-called lignin contains about 36.2 per cent combined water. Analysis shows that 2 lb. of the 50 per cent liquor contains 1 lb. water of solution, 0.2 lb. of combined water and 0.35 lb. of carbon, 0.45 lb. of ash. For this amount of liquor 0.14 lb. of salt cake may be added.

The heat required for evaporation and combustion may be calculated to have the following distribution:

B.t.u. required to evaporate 1 lb. water at 212 deg.	= 1052
B.t.u. required to raise this to 1600 deg. Fahr.	788
B.t.u. required to raise combined water to 1600 deg. Fahr	157
B.t.u. to raise products of combustion (12 per cent CO_2) to 1600 deg. Fahr.	2918
B.t.u. required to melt 0.45 lb. ash in liquor.	164
B.t.u. required to raise 0.45 lb. ash to 2000 deg. Fahr.	43
B.t.u. required to melt 0.14 lb. salt cake.	51
B.t.u. required to raise this to 2000.	13
B.t.u. required to reduce 0.59 lb. of Na_2SO_4 according to following equation: $Na_2SO_4 + 2C = Na_2S + 2CO_2 =$	146
	5332
B.t.u. figuring loss through furnace walls 10 per cent	533
Total heat	5865

It will be seen from the above that the heat in the liquor, viz., 5000 B.t.u., falls considerably short of the theoretical heat needed to carry on the reaction, and that it is this deficiency which must be supplied by radiant heat.

On the other hand it will be seen that a part of this heat is available for making steam if a steam boiler is placed in the pathway of the hot gases.

If we reduce the gases from 1600 deg. to 500 deg. we get:

B.t.u. from superheated steam	610
B.t.u. from products of combustion	2138
Total B.t.u. available for making steam	2748

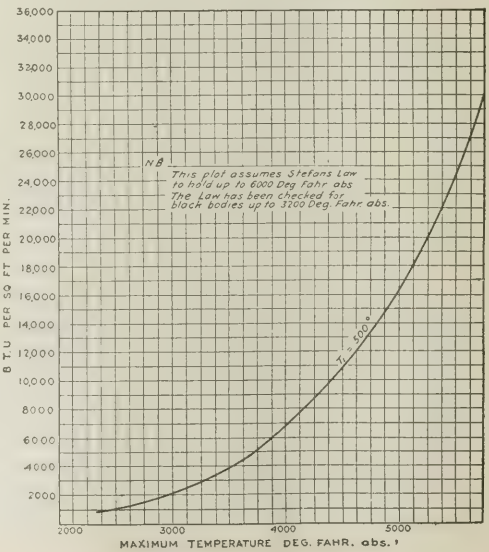

FIG. 1—CALCULATIONS, ASSUMING STEFAN'S LAW

Now we come to the problem of making up the deficiency. There are several ways by which this might be done, but only a few are practicable. If we had plenty of cord wood we could make it up in this way, and, in fact, we did at first. The results, however, were not satisfactory from the reduction side of the case. Coal can be atomized in the furnace and burned, but as all coal contains iron, it is objectionable on account of the difficulty of settling of the alkaline liquors which is occasioned by the iron. Furthermore, the coal contains ash which uses up the alkali, forming silicates and aluminates of soda, etc. It is also not satisfactory from a reduction point of view, as it requires an oxidizing flame.

Atomized crude oil was also tried, and though this gave a very hot flame furnishing the necessary amount of heat, it is not satisfactory from a reduction standpoint. Furthermore, the vaporization of the oil produces a cool zone in the place where it is necessary to have a hot zone tending to chill the smelted effluent.

Producer gas seems at present to be the most satisfactory way of supplying the extra heat needed. This enters the furnace hot and quality and quantity of the gas can be easily regulated. By constantly feeding the producer, we get a gas containing a large quantity of illuminants which are heated to high temperatures upon combustion of the gas and radiate heat to the particles of liquor to be evaporated, and these can be heated to a very high temperature by the burning of the already hot gas furnishing more illuminants.

Now if you will consider the following reactions, I think you will see the utility of this gas for reduction purposes:

$$\underset{328}{Na_2SO_4} + \underset{89}{2C} = \underset{194}{Na_2S} + 2CO_2 = -45.$$

$$\underset{328}{Na_2SO_4} + \underset{89}{4C} = \underset{116.5}{Na_2S} + 4CO = -123.$$

$$\underset{328}{Na_2SO_4} + \underset{22}{4CH_4} = \underset{89}{Na_2S} + \underset{121}{2H_2O} + \underset{97}{CO_2} = -43.$$

$$\underset{984}{3Na_2SO_4} + \underset{88}{4CH_4} = \underset{267}{3Na_2S} + \underset{484}{8H_2O} + \underset{116.5}{4CO} = -204.5$$

$$\underset{2296}{7Na_2SO_4} + \underset{106}{4C_2H_6} = \underset{623}{7Na_2S} + \underset{776}{8CO_2} + \underset{726}{12H_2O} = -277.$$

$$\underset{1640}{5Na_2SO_4} + \underset{106}{4C_2H_6} = \underset{445}{5Na_2S} + \underset{726}{12H_2O} + \underset{232}{8CO} = -343.$$

$$\underset{328}{Na_2SO_4} + \underset{89}{8H} = \underset{242}{Na_2S} + 4H_2O = 3.$$

$$\underset{328}{Na_2SO_4} + \underset{116}{4CO} = \underset{89}{Na_2S} + \underset{388}{4CO_2} = 33.$$

The numbers given in the above equations are in large calories per gm. molecular wt. taken.

It will also be seen that in all cases except the last two the reaction is endothermic. In the last two, viz., saltcake and hydrogen, and saltcake and carbon monoxide, the reaction is exothermic. Now if we could have either pure carbon monoxide or pure hydrogen come in contact with molten saltcake, we should have a reducing action which would not chill the molten liquor so as to congeal it.

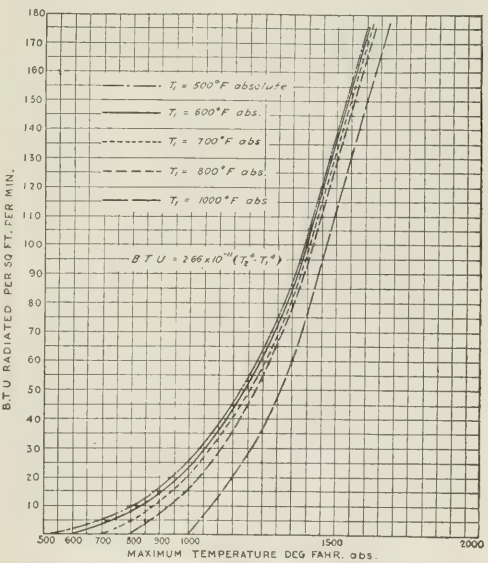
In order that there may be no misunderstandings, I want to say that the operations mentioned in regard to reduction in this paper must not be considered as taking place on pure sodium sulphate nor should the resulting product be considered as pure sodium sulphide. In every case we have a mixture of several ingredients, viz., sodium carbonate, sodium sulphate, sodium sulphide and probably a little sodium oxide. Sodium sulphide pure does not melt at 2000° C. and in order that this should run at ordinary temperatures it must be dissolved in other salts.

Now in the above figures we have figured the saltcake as if all was reduced by the carbon in the lignin liquor. We did this in order to show the distribution of heat and the total heat consumed. As a matter of fact, however, I doubt if very much of this salt is reduced by the carbon of the lignin as the lignin is burning in an oxidizing atmosphere and any sodium sulphide reduced here from contact with the heated carbon would to a large extent be oxidized to sulphate of soda. In fact there is a considerable amount of sulphate of soda found in the smelted effluent of the furnace. The reduction caused by the lignin may be greatly increased by the producer gas. This has been shown many times by stopping temporarily the gas and the liquor and testing the effluent. The reduction of this gas was so marked that many experiments were conducted, the main object being to obtain a better mixture of this gas with the effluent. In all these experiments the reduction was markedly increased but most of them were abandoned owing to mechanical difficulties which developed.

CALCULATED AMOUNT OF COAL TO BE BURNED IN PRODUCER

The question now arises as to the amount of coal necessary to be burned in a producer to furnish the required liquor per ton of pulp produced in the mill. From data obtained we find a coal which analyzes as follows:

	Per cent.
Fixed carbon	53.34
Volatile matter	39.25
Moisture	2.66
Ash	4.75
Total	100.00



B.T.U. RADIATED PER SQ. FT. PER MIN.
MAXIMUM TEMPERATURE DEG FAHR. abs.
T_1 = 500°F absolute
T_1 = 600°F abs.
T_1 = 700°F abs
T_1 = 800°F abs.
T_1 = 1000°F abs
B T U = 2.66 x 10⁻¹² (T_2^4 - T_1^4)

FIG. 2—CALCULATIONS, ASSUMING VARIOUS LOWER TEMPERATURES

and which has an ultimate analysis given as follows:

	Per cent.
Carbon	73.11
Hydrogen	5.88
Nitrogen	2.10
Oxygen	9.24
Moisture	2.66
Ash	4.28
Sulphur	1.73

This will give a producer gas which analyzes as follows:

	By Vol.	By Weight.
Carbon dioxide	3.9	7.32
Ethylene	3.2	3.75
Oxygen	0.1	0.13
Carbon monoxide	24.6	28.86
Methane	3.8	2.62
Hydrogen	17.7	1.51
Nitrogen	46.7	55.81
	100	100

If we assume the gas comes from the producer at 1200° F. and that we burn it with the theoretical amount of air we find the following amounts and distribution of heat for 100 lb. of gas:

Heat of combustion of 3.75 lb. ethylene	77,560	
Heat of combustion of 28.86 lb. carbon monoxide	126,200	
Heat of combustion of 2.62 lb. methane	56,190	
Heat of combustion of 1.51 lb. hydrogen	79,230	
Total	339,180	
Sensible heat 7.32 lb. carbon dioxide	2,228	
Sensible heat 3.75 lb. ethylene	1,820	
Sensible heat 0.13 oxygen	34	
Sensible heat 28.86 carbon monoxide	8,533	
Sensible heat 2.62 methane	1,869	
Sensible heat 1.51 hydrogen	6,494	
Sensible heat 55.81 nitrogen	16,500	37,478
Total		376,658

Now the simplest method of getting the heat radiated is to find the heat leaving in the products of combustion and subtract this from the total heat.

In doing this the following formulas are used:

$(2405+.0000119t)t$ = B.T.U. for 1 lb. N.

$(.19+.00006t)t$ = B.T.U. for CO_2.

$(.2104-.0000187t)t$ = B.T.U. for 1 lb. O.

$(.2405+.0000119t)t$ = B.T.U. for 1 lb. CO.

$(.42+.000103t)t$ = B.T.U. for 1 lb. steam.

Now if we assume that owing to radiation and convection the gases are reduced to 1600° F. going over the bridge wall we have a basis for getting the heat in the products of combustion. A simple calculation shows that for every 100 lb. of gas entering the furnace we have a total of 327 lb. going over bridge wall distributed as follows:

174.48 lb. of nitrogen from air
55.81 lb. of nitrogen from producer

230.29 total nitrogen

11.79 lb. CO_2 from ethylene
45.97 lb. CO_2 from carbon monoxide
7.20 lb. CO_2 from methane
7.32 lb. CO_2 from producer

72.28 lb. total CO_2.

Total of 327 lb. of gases going over bridge wall for 100 lb. of producer gas.
4.93 lb. steam from ethylene
5.89 lb. steam from methane
13.59 lb. steam from hydrogen

24.42 total lb. steam.

Now if we calculate the heat in these given amounts of products of combustion we find we have:

	B.T.U.
Sensible heat of above steam at 1600° F.	19,260
Heat in 230.29 lb. nitrogen at 1600° F.	95,610
Heat in 72.28 lb. carbon dioxide at 1600° F.	23,080
Total heat in products of combustion of 100 lb. of gas at 1600° F. going over bridge wall	137,950

The excess of B.T.U. in the gases generated over those contained in the products of combustion at 1600° F. is found by subtracting 137,950 from 376,658 which gives us 238,708 B.T.U. for 100 lb. of producer gas available as radiant heat to heat the particles of liquor.

Calculation from the ultimate analysis of the coal and the analysis of the gas show 1 lb. of carbon produces 3.729 lb. of gas, or that for every pound of coal burned in producer 14,050 B.T.U. are liberated. Of course all this heat does not come from the coal, but part comes from the steam blown into the producer. Assuming a loss here also of 10 per cent through furnace walls, we have a loss of 1405 B.T.U. to take from the heat of radiation, neglecting heat losses from furnace. We find that we get 2387 B.T.U. per pound of gas to be supplied by radiation and convection to liquor and from this we get B.T.U. per pound of coal, 8851. Subtracting from the latter the 10 per cent heat losses for furnace, 1405, we get 7446 B.T.U. to be applied to making up the 865 B.T.U. deficiency not supplied by the heat in the lignin.

Now let us take as a unit a mill producing 100 tons a day of Kraft pulp.

Wood for making such pulp varies all the way from 45 to 52 per cent cellulose according to kind used and location grown. Let us assume a pulp containing 48 per cent cellulose and 52 per cent lignin. Then a unit of 100 tons pulp would have a content of 108 tons of lignin in the black liquor.

As the dried liquor is 45 per cent ash we find that our 100 tons of lignin makes 197 tons of dried black liquor. Then we have 394,000 of solid matter or 788,000 lb. of 50 per cent liquor.

Multiplying 394,000 by 865 and dividing by 7446 we find that we must have at least a producer capacity of 45,760 lb. per day per 100 tons of pulp. Of course there should be some leeway for poor coal variations in strength of liquor.

As a matter of fact we have found a 20 per cent margin above this not excessive when we consider the troubles eliminated by not running close to the theoretical point where any of the many variables tend to

upset the operation even to the extent of clogging the furnace.

TANGIBLE RESULTS FROM ELIMINATION OF INCINERATOR

As a result, however, of the above process we have been enabled to produce over 1600 horse-power from our liquor in addition to recovering the heat generated in the gas producer. We saved all our hospital bills and damages arising from explosions, we reduced the repair bills in the furnaces enormously, we saved all the repairs on incinerator and disk evaporators and the power required to run same, we saved about 60 men's labor in various departments and, above all, got an even, uniform production of quality never obtained before. In addition to the above it alone was the means of increasing the production many times.

KEEPING BOILER TUBES CLEAN

We have already mentioned that the boiler tubes in the preliminary experiments got dirty from sublimed saltcake and carbonate of soda. The keeping of the tubes clean proved to be a much more difficult problem than we first thought. The sublimed saltcake first deposits on the tube as a powder, but if not removed the additional saltcake soon smelts the whole to a continuous lump almost impossible to remove. The obvious remedy was to blow the tubes often enough to keep this powder from accumulating on the tubes, but how to do this without affecting the operation of the furnaces was a problem. I might also add it is still a problem, for though we have a workable proposition I think there is still a large chance for improvement. If we opened the clean-out doors we spoiled our draft and consequently had to shut the furnace down. We tried automatic blowing, but these blowers would burn off in the vaporized alkali or plug up so we could do nothing. We even had doors made with a hole covered by a small door opposite each tube, but these were unsatisfactory in that we were blowing from the wrong end and the air or steam did not have force enough by the time it got to the fire end of the tube to remove the accumulation of salt and alkali. We finally evolved a scheme by rebuilding the back of the furnaces where we could have a slot on top covered by covers and a rake attachment locating the tubes horizontally. The tube blower was also graduated by a ratchet attachment to locate the tubes vertically. By this means the tube of each boiler is blown twice a shift. Each blowing takes twenty minutes and we run three shifts; it will be seen that two hours are required for each furnace for every twenty-four hours of operation.

ADDITION OF SALTCAKE

The next problem was the constant addition of saltcake in the required quantities to the liquor. We first tried putting the saltcake in the back of the furnace through a tube supplied with saltcake by means of a conveyor. This did not give us the results desired, inasmuch as this was not properly mixed with the liquor, and consequently a great deal passed through the furnace unchanged. In other words, our reduction to Na_2S was small and the desired liquor was not obtained. The next step was to put a horizontal agitating tank over each furnace and mixing the liquor and saltcake therein and supplying each furnace separately according to its consumption. This worked fairly well. The main objections to this was the increase in the amount of labor required and the clogging of the pipes with saltcake when it was necessary to close a valve. We were quite successful in the scheme described in U. S. Patent 1,130,317, Mar. 2, 1915, not described here on account of taking up too much space.

We finally evolved a scheme by which we put saltcake in a hopper from which it was carried to a grinder, elevated to a rotary screen and sifted, the fine particles going to a mixing tank and the coarse particles being returned to the grinder to be reground. The mixer tank was supplied with liquor from the storage tank installed to hold the evaporated liquor, and powdered saltcake added by calibrated diaphragms so that a given amount of saltcake was added for a given amount of liquor. The mixture was pumped to the furnaces through a pipe in which a very high velocity was maintained and the liquor not used in the furnaces was returned to the mixing tank also at a high velocity. The object of having a high velocity in the pipes is to prevent the saltcake, which is only slightly soluble in liquor of this concentration, from settling out. Special valves were designed on the outlets of this pipe so that they could be cleaned without stopping the operation and they were so set into the line as to prevent forming a pocket on the take-off. In addition to the above, many contrivances were adopted for handling this liquor, but as to describe them would stretch this paper to undue length I must omit them.

SETTING AND RESETTING BOILERS

Now, having described the amount of heat coming from the flue gases of the furnaces, it might be well to state the method of recovering the heat contained therein. Experiment had convinced us that the horizontal return tubular boiler was best adapted to our needs on account of the comparative ease, as compared with other types of boilers, by which the saltcake and soda could be removed from the tubes. This we set up following the standard accepted boiler setting. This was found to be a great mistake and the settings had to be entirely changed to meet the new conditions imposed on them. In explanation I wish to say that though saltcake, soda and sulphide of soda vaporize at high temperatures they may be sublimed at 1200° F. in a current of furnace gases. Now the shell of the boiler acts as a condenser and the hot molten alkali condensed forward of the peak in the boiler setting flowed forward into the furnace. But unfortunately all the vaporized alkali was not removed here, but a considerable amount was condensed on the boiler back of the peak and this either accumulated as a lake of molten alkali or gradually solidified or ran out of the clean-out door onto the blow-off pipes or the cement floor. I have at times seen streams of molten alkali as large as my arm so run out of these clean-out doors.

These furnaces had all to be rebuilt with a continuous slope from the clean-out doors to the furnace. Even the whole length of the shell of the boiler was insufficient to condense all the sublimed alkali and this would accumulate in the tubes at first as a powder, but if the tubes were allowed to get too dirty the powder being a nonconductor of heat insulated the boiler tubes and the next accumulation of sublimated soda landed in the tubes in a melted condition cementing this powder to a hard mass. Many and various were the schemes

tried to get over this trouble, and we are still experimenting.

DISSOLVING TANK LIQUOR

As previously stated, the smelt runs into the dissolving tank where it is dissolved in the weak alkali coming from the alkali room. Owing to the greater efficiency of reduction we obtained a dissolving tank liquor much stronger in sulphide content than ever obtained before. Owing to the elimination of the incinerator and the intermediate black ash process the sludge in the dissolving tanks is very much reduced and the pieces of half brick, stones, etc., are reduced to a minimum; thus the constant repairs of agitator arms, etc., were eliminated.

FLUE GASES

The gases from the smelting furnaces contain considerable quantities of alkali irrespective of whether the old or the new process just described is used. This alkali is in such a fine state of subdivision that it is practically impossible to remove it by any of the ordinary means. These gases were run through a tower filled with atomizers, filling the tower with a dense fog and yet the particles were so fine that they would not be precipitated. We finally decided to experiment with the Cottrell Process and made arrangements for the same with the Western Precipitator Co. Owing to the great quantities of moisture in our flue gases we were not very successful at first, inasmuch as the moist precipitate would short-circuit the apparatus. But after making many changes we finally evolved a modification of this process which works finely. This not only prevents a public nuisance but it yields large dividends from the saving of this precipitate.

FILTRATION OF DISSOLVING TANK LIQUOR

As stated before, the dissolving tank contains many impurities among which is carbon, furnace linings, iron sulphide, etc., etc. Now the treatment of this liquor depends on the question of whether or not you intend to recover your lime. If the lime is not to be recovered this liquor can be pumped directly to the causticizing tanks. If, however, it is the intention to recover the lime it is necessary to filter this liquor from all the suspended matter, otherwise every time the lime was recovered there would be an addition of these impurities which would make the recovery impracticable. We have found that the best way to handle this is through a filter press. Here, however, we run up against a great difficulty, though this first made itself apparent in the causticizing operation to be described later on. The canvas used in the filter press does not stand alkali and required renewal so often that it was a source of considerable expense. This difficulty was partially overcome by treating it with a special rubber solution, depositing the rubber on the canvas threads and yet leaving the cloth porous. There is still chance for improvement here. The liquor after being filtered is sent to the alkali room.

ALKALI ROOM

In this room the liquor from the dissolving tank is causticized. This room consists of a large number of settling tanks fitted with siphons, lime, baskets, agitators and steam pipes for blowing in live steam. Here the liquor is tested and the calculated amount of lime added to the slacking baskets, steam blown in and the tank agitated, after which the precipitated carbonate of lime is allowed to settle. The supernatant liquor is siphoned off and weak liquor added from a previous washing and the operation repeated. Finally, the fourth washing is done with water after which the sludge is sluiced. As will be seen this process involves a large installation and requires a considerable amount of steam as well as considerable amount of time. Now the time factor is important inasmuch as if anything happens so that you become short of cooking liquor the digester plant has to shut down more or less waiting for these tanks to settle. Furthermore, the very nature of the process is such that it invites waste by either not washing properly due to neglecting one washing or due to incomplete settling on account of trying to catch up with the digesters, or losses may occur easily by intentional or unintentional manipulation of the labor employed.

In order to eliminate these wastes a filter press was installed which enables us to dispense with the settling and leaves many of these tanks available for storage of liquor. The lime sludge can be washed in the filter press with much less water than is used in the decanting or settling process and may be washed much freer from alkali. Furthermore, if the dissolving tank liquor has been filtered the lime sludge is in a condition for recovery of the lime. This operation allows us to make a stronger alkali solution than we otherwise could, and consequently we can use more black liquor as a filter in our digesters later on. This also means less evaporation later on.

RECOVERY OF LIME SLUDGE

We have experimented quite successfully on the recovery of the lime sludge, but up to the present have not put in an industrial plant. As this is not operating on a large scale I will not go into this here, but may in a future paper show how this is done. The method which gives the greatest promise is the electric furnace method, whereby we get pure CO_2 and recover our lime. We have installed a large experimental electric furnace with this end in view and expect to work it when our water-power development is completed.

DIGESTER HOUSE

The alkali from the filter press goes to storage tanks and thence to the digesters already filled with chips, where it is mixed with a certain amount of black liquor (used as a filler). The digester is steamed and cooked in the usual way. We however, made one very important change here. Instead of blowing relief into water to heat it we constructed a condenser and condensed the relief after first having separated it from the liquor which is contained.

There were three objects in view here. First, there was a limitation placed on the use of our pulp for many purposes, owing to the odor in bags used for holding flour, etc. My experiments had convinced me that a lot of this odor came from the use of this wash water. To get rid of this odor was the primary object but of course we wanted to save the heat.

Turpentine Recovery.—Our experiments had also shown that this relief contained large quantities of turpentine which, with the exception of the odor, tested equal to the best gum turpentine obtainable and far superior to wood turpentine. We consequently constructed, in addition to the condenser and separator

plant previously mentioned, a turpentine plant in which we separated the crude turpentine, made refined turpentine and finally a plant for deodorizing it from the mercaptan smells which accompany it. We have not been able to completely remove the odor, but have so far succeeded that we are enabled to sell our whole production at good prices.

VOMIT STACK GASES

After a digester is cooked the charge is blown into tanks to receive the pulp and liquor and the liberated steam is allowed to escape through a vomit stack. A calculation showed that there might at times be as much as 18,000 lb. of steam liberated in the course of a five-minute blow. Now here is over 20,000,000 B.T.U. per blow going to waste.

To save this we designed special condensers to condense this steam and heat the condensing water so that it could be used for washing the pulp.

VOMIT STACK PULP

Experiments had also shown that this vast amount of steam carried along with it a certain amount of pulp which except for these experiments would have entirely escaped our notice. This pulp, however, which is of the finest quality and should be saved for its own value, must be removed from the vomit stack steam before it enters the condenser, otherwise the plugging of the condenser is liable to follow. To do this we designed a special separating device somewhat on the principle of the cyclone so commonly used in separating shavings from air. This, however, was made with a pipe in the center which was closed at the bottom and had holes in it near the top for the outlet of the escaping steam. The steam was blown in at a tangent to the separator and circulated spirally up the separator, plastering the pulp over the side by its centrifugal force while the steam, now freed from pulp, passed to the condenser. Devices were also arranged for washing this plastered pulp from the sides as soon as the blow was completed.

The above not only enabled us to save an appreciable quantity of pulp but furnished us with immense amounts of hot water practically free of cost, enabling us to make a better and cleaner pulp.

WASH ROOM

The pulp from the digester is washed in the usual manner, though even here we have devised a machine on the counter-current principles of washing which looks as if it would revolutionize the whole washing end of the business. At present it is too soon to say much about this.

LIQUOR FROM WASH ROOM

This liquor instead of going direct to the evaporators goes to a filter press, and it is found that we obtain a considerable saving in pulp. Not only this, but the removal of this pulp from the liquor makes a direct saving, not due to the pulp, but an indirect saving which is even of far greater importance. I refer to the trouble eliminated in the evaporator room by being freed from the accumulation of pulp in the last effort which seriously interferes with evaporation.

We have now completed our cycle, being back where we started. In the foregoing we have not taken into consideration all the departments of the mill. Many of these are undergoing changes, but enough has been said to show that the chemical engineer can play a most important part in the renovation of this kind of mill at least. My own personal opinion is that the chemical engineer has a great opportunity in any mill involving a chemical process. In closing I may say that the average manufacturer considers the chemist and the chemical engineer as non-productive labor and classes them with the office help. As a matter of fact, the chemical engineer can probably not only save him more money than any other department of his mill but also produce him more money.

Chemists in War Service.—The American Chemical Society points out the advisability of following the lead of our Allies in assigning technically trained chemists to chemical service. Lacking an exemption of any group of men as a class, it is unofficially recommended that chemists of military age selected by draft and accepted for service should submit to their local boards a certificate from their employers or college as to their education and nature of present occupation, together with a request that they be allowed to continue in chemical work, either in private plants or in the military service. In any case, the secretary of the society should be promptly notified by members of any change in enrollment.

Operating Details of Zinc Retort Furnaces

By Edward Mackay Johnson

Superintendent Eagle Picher Lead Co.

LIGHT, VENTILATION AND SANITATION

Light, ventilation and sanitation all have at least an indirect bearing upon the recovery of zinc, and in designing a plant, or even in one already in operation, they should receive due consideration. While most of the furnace men do not work over five or six hours per shift as a rule, the rapidity with which they make up and charge a furnace has a decided effect upon the recovery of zinc. The men can do just as good, and at the same time faster work, provided their working conditions are favorable.

Work on the furnaces in the summer time is very hot and trying on the men at the best, and any relief in the way of improved conditions will not only add to their comfort, but will pay for the cost, both in the increased recovery of zinc and in retaining a more efficient organization. Considerable advancement has been made along these lines in the past two or three years by blowing fresh, cool air upon the men while at work during the hot months of summer. A number of the plants have also constructed convenient wash rooms. It is unfortunate, however, that the men in a good many cases have not shown their appreciation of the companies' endeavors to improve their conditions.

FURNACE WORK AND TOOLS—NATURAL GAS FURNACE

Head Charger.—The first duty of the head charger upon coming to work is to mark any bad retorts in the furnace. He then assists in drawing the first four sections of the furnace. As soon as the draw-car and blow-out shield (through which also the retorts have been "bumped") are out of the way, the charger, with a specially constructed scoop (Fig. 1), commences

FIG. 1—CHARGING SCOOP

charging the retorts with material from the charge-car, which travels on a near-by track parallel with the furnace. He should fill the retort from back to front without leaving any "nests" in the charge. Each retort should be "spieced" as soon as charged by inserting a small iron rod along the top of the charge to prevent the charge from blowing out. Each retort should be examined before recharging to see that it is neither cracked nor has a hole in it. The head charger and second charger work in turn, charging five retorts apiece as a rule. After the furnace is completely charged, the head charger cuts out the bad retorts, helps pull them out, and put in new ones. He should also look after changing any bad plates or pillars.

Second Charger.—The first duty of this man is to oversee and help to turn and mix the blue powder with the proper amount of coal and water, being careful to obtain a thorough mix. He now helps draw the first four sections of the furnace and assists in bumping out the retorts in the first section. He then alternates with the head charger in charging the furnace, and helps the stamper (the man behind the car) patch up any holes in the furnace as they go along. As the new retorts are placed, he stamps them with furnace mud.

Man Behind the Charge Car, or "Stamper."—While the first four sections of the furnace are being drawn, the stamper helps in any way he can, pushing the draw-car along, etc., and then he draws the remainder of the furnace down to the blue powder. He then works behind the charge-car, laying the condensers over by the furnace so that the "loamer," or man behind car, can place them upon the castings. The stamper now sets the condensers by placing the butt about an inch into the mouth of the retort, resting the small end or mouth of the condenser upon the "grasshopper" (a small casting somewhat resembling the leg of a grasshopper), adjusting the condenser in its proper plane with respect to the retort, and with the bottom of the condenser practically horizontal. Another important duty of the stamper, and the one from which he gets his name, is to stamp the furnace mud into the openings left wherever new retorts are put in. The stamping tool (Fig. 2) must be hot to prevent the clay from adhering to it.

FIG. 2—STAMPING TOOL

He also shovels one-half of any charge spilled during charging back into the charge-car. He goes ahead and draws the blue powder as soon as it is ready. With the aid of the "loamer" he scrapes off the luteing material from the castings, and cleans up the floor between the track and furnace.

Man Behind the Car, or "Loamer."—The loamer's duties consist of the following: He helps the stamper draw the furnace from the fourth section to the blue powder; places the condensers upon the castings; closes the spaces between the retorts and condensers with loam as the stamper adjusts them to position. The loam usually consists of about five parts coking coal, one part dirt and one part residue, mixed together and moistened with water. While loaming-up he also closes the mouth of the condensers with "stuffing," which may be non-coking coal or samplings from the mouth of the retort mixed with furnace tops. The loamer also helps the stamper scrape off the castings and clean up the floor between the furnace and charge-car track.

Chiseler.—This workman helps to turn the blue powder; chisels and pries the condenser loose from the retort with a chisel bar (Fig. 3); chips that part of

FIG. 3—CHISEL BAR

the broken condenser which contains material valuable enough to be retreated, breaks it up fine and turns it into the blue powder. He also cleans up the floor on the outside of the track and puts in six pans. He gets the clay from the pottery and wheels in the coal for the blue powder; hooks the burnt clay out from between the retorts that are to be changed; carries the pole to

take the new retorts from the preheating kilns to the furnace, and shovels one-third of the blue powder over by the furnace for the charges.

Blow-out.—The first duty of the "blow-out" is to clean the floor and dump the furnace pans. He then takes down the condensers as the chiseler cuts them loose, and samples the mouth of the retort—*i.e.*, he rakes out any oxide of zinc or the richest of the residue, which is nearly always at the mouth of the retort. He scrapes the samplings from off the castings upon the furnace pans, which material goes to the blue powder for the next shift. He pulls these pans out and sweeps up the floor as he goes along, leaving open the channels to the cellar.

He now proceeds to "blow out" the retorts by means of an iron pipe (Fig. 4) drawn to a point and perforated

FIG. 4—BLOW OUT HOSE AND PIPE

with small holes at the end, through which a spray of water under pressure issues. The pipe is inserted through the blow-out shield to the end of the retort with a firm, steady push. As the spray of water enters the hot residue, the rapid generation of steam causes an explosion on the inside of the retort, which ejects the residue from the retort against the shield, whence it falls into the cellar below. The blow-out also puts in the last four pans, shovels one-third of the blue powder over to a convenient place for the chargers, helps the bumper carry the retorts from and to the furnace by means of the goose neck (Fig. 5). He also helps to

FIG. 5—GOOSE NECK OR RETORT CARRIER

clean up the clay from in front of the furnace after the retorts are charged.

Bumper.—The "bumper" helps turn the blue powder, bumps the mouth of the retort free from any burnt loam, etc., and with the same tool (illustrated in Fig. 6)

FIG. 6—BUMPING TOOL

rakes any slag or residue that remains in the retort after blowing out. He works through a slot in the same shield used by the blow-out, alternating with the latter in his work. He cleans the castings after bumping with a hoe (Fig. 7), puts in the second six pans, shovels

FIG. 7—TOOL FOR RAKING OFF THE CASTING

over one-third of the blue powder to the charges, helps take out broken retorts and put in the new ones, and helps clean up clay, etc., after the retorts are all changed.

Condenser Boy.—The duties of the "connie" boy consist in scratching the blue powder and oxide of zinc from the inside of the condenser with an iron button riveted to the end of a light iron rod (Fig. 8). He also

FIG. 8—SCRATCHER BUTTON

bumps off any zinc crust or burnt loam from the outside of the butt of the condenser (Fig. 9), keeps the charge shoveled down in the charge car, and sweeps up the furnace floor outside the charge-car track. After the

FIG. 9—CONNIE BOY'S BUMPER

furnace is charged he keeps the condensers spieced up by introducing through the top of the stuffing a small iron rod drawn to a point. If, after spiecing, a flame shows at the butt of the condenser, he "patches up" or throws fresh loam around the place burning out. He screens the samplings and gets the stuffing ready. One condenser boy attends to two furnaces or one block after 11 a. m. The condenser boy as a rule uses the same buttons that the metal drawer drew the furnace with.

FIG. 10—TOOL FOR HANDLING CONDENSER

Metal Drawer.—The metal drawer, as the name implies, draws the zinc and scratches the oxide of zinc and blue powder from the condenser into a ladle by means of the scratcher button (Fig. 8). In the West he commences to draw the blue powder about 3.30 p. m., finishing about 4.30 p. m. At 4.45 p. m. he commences at the first section of the furnace and draws the charge through to the blue powder, finishing about 7.30 p. m. He makes the second draw in the same way, commencing about midnight and finishing about 3 a. m. The third or morning draw is made by the "half-shifters." The metal drawer should scratch the condenser clean, but should not pull any more hot residue (or "fire") from the mouth of the retort than is necessary to keep the zinc from freezing in the ladle. This should be specially guarded against if the ore carries much lead or iron, as these elements would then be unnecessarily increased in the spelter.

Stuffer.—As fast as the condensers are drawn, the "stuffer" stuffs and lights them, cleans up the scrap and piles the metal.

FIG. 11—TOOL FOR SAMPLING MOUTH OF RETORT

Day Fireman.—The day fireman has general supervision over his block and its workmen. He comes to work about 3.30 a. m. with the half-shifters, or the men who make up the furnaces. In addition to overseeing the work he works over the blow-holes and cleans out bad retorts that appear during his shift. His most important duty, of course, is the actual firing of the block. He therefore has to regulate the supply of air and gas by means of the main air gate and gas valve, and the small air "shievers" on the furnace.

It is almost impossible to describe the actual process of firing, and only a general idea can be given. The method of firing varies not only for different ores, but sometimes on the same ore at different plants. Assume that the furnace is practically worked off, and is at the critical temperature which the retorts will stand. If the night fireman has not already done so, the day fireman will somewhat reduce the air on the whole furnace as soon as he comes on duty by means of the main air gate, and if any sections of the furnace appear to be too hot he will also close the small shievers at those particular places. As the furnace is drawn, he "cuts-in" these shievers behind the draw-car, which operation necessitates reducing the volume of gas entering the furnace by means of the main gas valve. The small gas valves on the furnace are seldom used. As the furnace is charged the fireman opens up these shievers behind the charge-car, thereby burning the gas closer and more rapidly heating that part of the furnace which has been charged.

It is at this point that the firing may vary. In some cases the shievers are opened rather wide, in order to heat the charge rapidly and obtain a heavy flame at the mouth of the condensers in a short time, then "cutting-in" the shievers sufficient to properly regulate or settle this down. In some cases the shievers behind the charge-car are not opened so wide, thereby bringing the heat up more gradually, not permitting the heavy flame to appear at the mouth of the condensers. The main idea in either case is to so regulate the amount of air and gas entering the furnace to get the latter permanently adjusted for the shift, at the same time increasing the heat of the charge so that it is sufficiently worked off in the allotted time. The method of firing an ore depends on whether it is hard or soft, or gives up its zinc with difficulty or with ease.

In either case the day fireman usually has the furnace "settled down" between noon and 2 p. m., according to the nature of the ore and the time the men start and finish making up the furnace. After the furnace is settled down, the small shievers are not disturbed much. The furnace is kept gradually "coming" by means of opening the main air and gas valves a little from time to time as needed.

Night Fireman.—As a rule the night fireman simply continues to keep the furnace "coming" as above, or he may also open up the small shievers a little, his main object being to have the furnace (or at least the first four or five sections) so fired that very little flame is showing at the mouth of the condensers by the time the men come to work in the morning, which is about 4 o'clock.

In addition to firing the block, he oversees the metal drawing, stuffing the condensers, patching up and spiecing, and cleaning out any bad retorts that may show up.

COAL FIELD FURNACES

Hegeler Type.—As this furnace is charged from end to end, the same as in the gas-fired type, the furnace work and tools are very similar, so far as the writer's experience goes. The principles of firing are also essentially the same.

The main feature of this type of furnace is that the artificial gas generated from coal by means of a producer passes directly into one end of the furnace and out at the other without any regeneration, the waste heat being conducted under boilers at the end of the furnaces.

Neureuther Type.—There does not exist enough difference between the tools used by the men in making up this type of furnace and those used on the natural gas furnace to warrant further description. The details of the work are also practically the same, but owing to the fact that the whole bottom row of retorts is charged at one time, working from the bottom row to the top row, the general system varies somewhat.

In making up a furnace of 400 retorts it is divided into four machines, each of 100 retorts, and a crew of three men. Each crew makes up its part of the furnace practically independently of the other crews. In this type of furnace the retorts are changed first instead of after charging. The furnace, instead of being drawn from end to end in the morning by two half-shifters using a draw-car, is drawn by all of the half-shifters working at the same time. Hand ladles are used to make this draw. The furnace is therefore quickly drawn, requiring only ten or fifteen minutes. In this type of furnace instead of charging from cars the mix of ore and coal is strung along in front of and parallel with the furnace. While the residues are sometimes raked out of the retorts in the gas field, in this type of furnace they are always raked out regardless of the kind of ore smelted.

The foregoing practically covers the essential variations in the work upon that type of furnace which is charged and worked off from end to end, and on one that is charged from row to row, and the whole furnace worked off at the same time.

Henryetta, Okla.

The Action of Aluminium Chloride Upon Solvent Naphtha[1]

By Robert J. Moore and Gustav Egloff

The following paper is the application of information obtained in a previous work[2] on pure aromatic compounds to commercial sources of aromatics. The first paper dealt with the action of aluminium chloride upon pure benzene, toluene, xylenes, cumene and cymene. The starting oil used in the following work was a commercial solvent naphtha derived from the thermal decomposition of coal.

SOLVENT NAPHTHA USED

The solvent naphtha used in these experiments was the usual commercial product of approximately 65 to 70 per cent of xylenes and contained ethyl benzene, trimethyl benzenes and higher derivatives of benzene, traces of unsaturateds and paraffins with about two per cent of naphthalene and naphthalene derivatives.

DISTILLATION ANALYSIS

Specific gravity 0.868 at 15.5 deg. C.

The distillation was conducted in a standard 100 c.c. Engler flask.

Temperature Deg. C.	Per Cent by Volume
134.8	1st drop
135.0	0.6
140.0	47.3
145.0	79.4
150.0	85.6
160.0	93.0
170.0	97.7
180.0	99.1
181.0	Dry Point

[1]A paper read before the Industrial Section of the American Chemical Society at the Spring meeting in Kansas City, Mo., April 14, 1917.

[2]This journal, vol. XVI, 1917, Moore and Egloff.

Upon sulphuric acid treatment a lemon color was noted in the acid layer.

Experimental Procedure

The formation of benzene and toluene from solvent naphtha may be accomplished by the action of anhydrous aluminium chloride or by generating the aluminium chloride within the body of the liquid by passing hydrogen chloride gas over aluminium powder or filings in the presence of mercuric chloride. The formation of aluminium chloride within the body of the oil by passing hydrogen chloride over aluminium is enormously increased by the addition of a small amount of mercuric chloride which seems to be catalytic in its action.

Both methods of using aluminium chloride were tried in these experiments. In the anhydrous aluminium chloride experiment a charge of 5 per cent by weight of aluminium chloride was added to one liter of solvent naphtha. The distillation of the solvent naphtha was conducted in a round bottom flask of two liters capacity, with a Hempel column to which was attached a 24-in. Liebig condenser. The distillation was conducted so that in a 24-hour run 78.1 per cent of the liquid distilled over. During the distillation copious volumes of hydrogen chloride came over with some of the volatile aluminium chloride, which in part clogged the condenser tube, and a small quantity also separated out in the bottom of the receiving flask. The distillate was neutralized with a 10 per cent sodium hydroxide solution, washed and dried over fused calcium chloride. The residue in the flask upon cooling solidified in part to a heavy black tar, with a layer of lemon colored light oil upon the surface of the tar. This residue was shaken with sodium hydroxide and filtered free of aluminium chloride compounds of some of the hydrocarbons present and free carbon. The oil layer was separated, washed and dried. The dried oil was analyzed for its benzene and toluene content by a method devised by Rittman, Twomey and Egloff.[3]

In forming aluminium chloride within the body of the oil by the action of dry hydrogen chloride gas upon aluminium powder or shavings in the presence of a trace of mercuric chloride, a charge of one liter of solvent naphtha was used in the same flask as in the above experiment with a slight modification later described. One per cent by weight of powdered aluminium was added to the liquid and 0.1 per cent of mercuric chloride. A glass tube was passed through a hole in the cork extending to the bottom of the flask and attached to the hydrogen chloride generator. The hydrogen chloride was generated in a Freas apparatus by dropping conc. sulphuric acid of 1.84 specific gravity upon ammonium chloride. The gas was washed and regulated by a Dreschel wash bottle containing conc. sulphuric acid. The formation of aluminium chloride can readily be noted by a reddish flecking upon the sides of the flask. This reddish liquid soon colors the whole mass of solvent naphtha to a deep red, increasing toward a blackish looking mass.

The solvent naphtha is best added to the aluminium in the flask, covering it and then adding the mercuric chloride. The distillation was carried on over a period of twenty-four hours and yielded a distillate of 82.3 per cent of the initial charge of 1 liter. The distillate and residue were neutralized, washed and dried. The method of analysis of the oil for its benzene and toluene content has already been referred to.

[3] *Met. and Chem. Eng.*, 13, 682, 1915.

Analytical Data

	Anhydrous $AlCl_3$	Generated $AlCl_3$	Anhydrous[4] $AlCl_3$ on Pure Xylenes	Temperature[5] and Pressure 150 lbs. on Solvent Naphtha 750°	800°C
Recovered oil	0.870	0.872	0.871	0.940	0.989
Per cent of recovered oil 78.1		82.3	97.6	51.6	37.3
Per cent benzene in recovered oil. 1.9		1.5	5.8	19.1	42.5
Per cent toluene in recovered oil.17.9		17.6	19.5	39.9	17.3
Per cent of benzene basis of original oil 1.5		1.9	5.6	9.8	15.9
Per cent of toluene basis of original oil 13.9		14.5	19.0	20.6	6.5

The percentage yields of benzene and toluene by the two methods of using aluminium chloride are not markedly different so as to state definitely any advantage of one over the other as to yields. The percentage yield of toluene is approximately 25 per cent less when using solvent naphtha in comparison to pure xylenes. As has been shown in a previous communication[6] this would indicate less susceptibility of benzene and toluene formation under the conditions of the experiment from higher derivatives of benzene than xylenes. A comparison of the data of aluminium chloride treatment of solvent naphtha with thermal and pressure decomposition indicates that the cracking of solvent naphtha under temperature and pressure yields greater percentages of benzene and toluene as shown in above table.

Summary

1. From the results of a research on pure aromatic compounds with aluminium chloride, a commercial oil, solvent naphtha, was subjected to the same treatment with a view to obtaining benzene and toluene.

2. Two methods of experimentation were used and compared:

(a) Anhydrous aluminium chloride.

(b) Generating aluminium chloride in the body of the oil by the action of hydrogen chloride on aluminium in the presence of a catalyst.

3. A table of comparison is given involving the yields of benzene and toluene from the following methods:

(a) Action of aluminium chloride on pure xylenes.

(b) Action of aluminium chloride on commercial solvent naphtha.

(c) Cracking solvent naphtha under temperature and pressure.

Some Applications of Magnetic Analysis to the Study of Steel Products*

By Charles W. Burrows

Introduction

The possibility of making use of magnetic determinations for estimating the mechanical properties of steel has long been before our minds, a great deal of experimental work has been carried out, and many questions have been answered. The fundamental principle that there is an exact correspondence between magnetic and mechanical properties has been established beyond doubt. Considerable headway has been made in the practical application of this principle. At the present time laboratory tests are being made upon tools, cutlery, springs, ball bearings, cables, rails and a few other articles. Not only are the laboratory methods capable of being expanded into practical shop or commercial tests, but the actual development along certain lines is in progress.

Definition of Magnetic Analysis

The science of magnetic analysis consists of the systematic correlation of the magnetic and other properties of materials and of the application of the laws and principles which underlie the interrelations of such properties, particularly the interrelations of the magnetic and mechanical properties of steel. It is based upon the fundamental fact of observation "that there is one, and only one, set of mechanical characteristics corresponding to a given set of magnetic characteristics, and conversely there is one, and only one, set of magnetic characteristics corresponding to a given set of mechanical characteristics."[1]

The art of magnetic analysis consists in the determination of the magnetic characteristics, or better, a small number of the magnetic characteristics, and from these observations making estimations of the mechanical properties.

Criteria of Mechanical Properties

The nature of a piece of steel may be studied by observing its behavior under the action of certain mechanical forces. The usual mechanical tests result in the destruction of the specimen so that it is not feasible to give such a test to the identical material to be used in a given structure. Even such superficial and intensely localized tests as the Brinell ball hardness test and the scleroscope test require the finishing of the surface tested, and after their application leave the surface in a modified condition.

Another very common way of examining steel is to determine its chemical constituents. The chemical analysis is extremely valuable and is usually considered as being the most valuable criterion of the mechanical possibilities of the steel. This test also must be made on a part of the material which does not enter into the final structure. The assumption must be made that the sample analyzed is substantially of the same composition as material to be used in the construction. The chemical analysis, however, is entirely inadequate to tell what condition the steel may have been left in as a result of its previous thermal and mechanical treatment.

In order to determine whether the steel has had proper heat treatment for a given purpose it is customary to examine the structure of the steel under the microscope, after the surface to be examined is carefully polished and etched by some suitable means. However, the microscopic analysis becomes difficult in the fine-grained steels. Here the structures of steels of slightly different heat treatment are so nearly alike that it is possible to make only a rough estimation of the heat treatment from the microscopic observations.

The mechanical, chemical and microscopic analyses of steel form the basis for the customary specifications and testing. They are, however, open to one or more of the following objections:

1. The test is vicarious. The actual material which is to be used in practice is not itself tested. Usually a certain percentage of the gross amount of material is set aside for test and the remainder is used in construction. This assumes either that the material is all homogeneous or that if non-uniform the test sample is a true representative of the entire lot. It is only by extreme care that either of these assumptions is even approximately met.

2. The test is destructive. In the tension test the specimen is usually broken. The chemical examination changes the nature of the material so that it no longer has the properties of the original. Hardness tests mar the surface to greater or less degree. This destructive nature of a test renders the piece tested unserviceable, no matter how excellent it might have been before the test.

3. The test is local. Chemical analysis may be made upon a drilling, which constitutes only 1 per cent of the sample submitted for test, which sample itself might be considered as representative of one hundred times its own magnitude. A hardness test involves still less material and even this small amount lies within a short distance of the outer surface of the test specimen. The limit of minuteness, however, is attained by the microscopic sample. The usual micrograph represents an area of less than one millimeter in diameter and is quite superficial.

4. The test may be qualitative. Some of these tests are valuable only when compared with similar tests on other material which may be considered as reference material.

Determining Factors in the Mechanical Properties of Steel

It is well known that two pieces of steel which differ in any one of a number of particulars show correspondingly different mechanical properties. It is well supported by experimental evidence, but not so generally known, that two pieces of steel which differ in certain particulars, likewise show corresponding magnetic differences. It is not feasible to go into great detail on this point at this time.[2] For the purposes of the present paper it is sufficient to give a few rather well-known examples of this correlation.

The changes that are brought about by adding certain chemical constituents to steel are well known. In

*A paper, with certain omissions, presented at the Atlantic City meeting of the American Society for Testing Materials, June, 1917.

[1]Burrows, "Correlation of the Magnetic and Mechanical Properties of Steel," *Bulletin*, Bureau of Standards, Vol. 13, p. 207 (*Scientific Paper No.* 272).

[2]In a scientific paper soon to be published in the *Bulletin* of the Bureau of Standards will be given many details on the correlation of the magnetic and mechanical properties of steel. This article will contain a rather comprehensive bibliography.

many cases the corresponding magnetic properties have been studied. With increasing carbon content in a hypo-eutectoid steel there is an increase in hardness and tensile strength and a decrease in toughness. Magnetically an increase in carbon content is accompanied by an increase in coercive force and hysteresis, and a decrease in permeability. Many other cases might be cited.

Mechanical operations also bring about corresponding changes in both the mechanical and the magnetic properties of steel. The cold drawing of a carbon steel increases its tensile strength and simultaneously increases its coercive force and hysteresis. Cold drawing also decreases the magnetic permeability.

The influence of heat treatment upon the properties of steel is fairly well known. A 1 per cent carbon steel quenched in water from a temperature above its critical point has a greater tensile strength than the same material in the annealed condition. Its hardness is also increased while its toughness is greatly decreased. Magnetically, changes of equal magnitude also occur on quenching. The quenched steel has a greater coercive force, a greater hysteresis, and a lower permeability.

In a specific case a 1 per cent carbon steel in the quenched and the annealed conditions had Brinell hardness numerals, in terms of kilograms per 0.1 mm. indention of 4390 and 800 respectively. The corresponding values of the coercive forces for a magnetizing force of 150 gausses were 33 and 12.

Steel changes with lapse of time. The course of this change is not so well known as some of the above changes. However, both mechanical and magnetic changes occur. Glass-hard steel softens with age. The same steel shows a decrease in coercive force.

The mechanical properties of a bar of steel may differ from point to point if the bar has not received the same treatment throughout. For instance, if a uniform bar is given a slight bend and again straightened it will show a slight change in its mechanical properties. There will be an increase in both hardness and tensile strength. The same bar will show a corresponding decrease in permeability in the same region.

Even during the operation of stressing a bar we feel sure that changes in the mechanical nature are occurring. Less is known about this phase of the problem than the preceding. However, we do know that small alternating stresses, even though well within the elastic limit, leave the material mechanically fatigued and if the stresses are repeated often enough rupture occurs. While it is difficult to study the changes in mechanical properties after repeated or alternating stresses, the magnetic problem is quite simple and has been investigated to some extent.

PRACTICAL APPLICATIONS OF MAGNETIC ANALYSIS

Magnetic analysis may be applied to determine the nature of the steel as a raw material, as a finished product, or even after it has been subjected to service conditions.

RAW MATERIAL

It is obvious that one cannot get a good product from inferior materials. Consequently it is desirable to know the nature of the raw stock that enters into the construction of the finished product.

Raw material must be uniform in quality. The proper mechanical and thermal treatment must be determined for each steel that is used. It very frequently happens that two steels of quite different composition may give equally good performance for a particular service provided each steel is given the appropriate heat treatment. In general the heat treatments required for the two steels will be different. It is desirable, therefore, that all the different bars of a given lot of material shall be of the same quality as the material for which the proper heat treatment was determined. Such assurance requires the examination of every individual bar of steel.

The requirement that all bars shall be alike in properties, implies that each bar shall have the proper composition, shall be properly forged, rolled or drawn, as the case may be, and shall be free from local imperfections such as blowholes, segregation, etc.

Occasionally a lot of steel of the wrong composition is supplied through error; or, by some chance, a single bar of different composition may get mixed up with the general stock. If not detected such a bar may cause much loss or annoyance. Very frequently a steel, especially among the alloy steels, may have the proper chemical composition but with the elements not in the proper state of solution.

Another defect that sometimes is found in cold-drawn material is the tearing apart of some of the crystals beneath the outer surface.

Many of these defects would pass unnoticed in the usual examinations by the chemist, microscopist, or mechanical tester. In such cases as the above a magnetic examination may be expected to be of service.

FINISHED STEEL PRODUCTS

The individual test not only permits the elimination of defective pieces but also permits the grading of a product which, while satisfactory in general, is not all of the same degree of perfection. This process of grading will enable the manufacturer to offer a uniformity of product hitherto unknown and permit him to guarantee such uniformity with surety. It is true that certain tools will have to be sold as seconds at a reduced price. On the other hand there will be a new class of exceptional quality which will bring a correspondingly higher price.

The individual test will permit improvement in design. At present we insist upon factors of safety so large that there would be a reasonable factor of safety even though there were a considerable amount of defective material. For example, a cast-iron structure might have a factor of safety of ten while a similar structure of steel would be safe with a factor of four or five.

Frequently it is desirable to make exhaustive tests upon a few pieces. Such cases arise where one or more samples are submitted in competition with other material. I recently witnessed a test on the results of which an order of $200,000 was to be based. Five pieces worth about $2.00 each were submitted by each competitor. The properties of each sample depended upon proper composition and proper heat treatment. Even though the composition were correct a slight error in the heat treatment would place the material at a disadvantage. By a suitable magnetic test the manufacturer could have assured himself that his samples were representative of his best product.

I have made laboratory tests on a number of com-

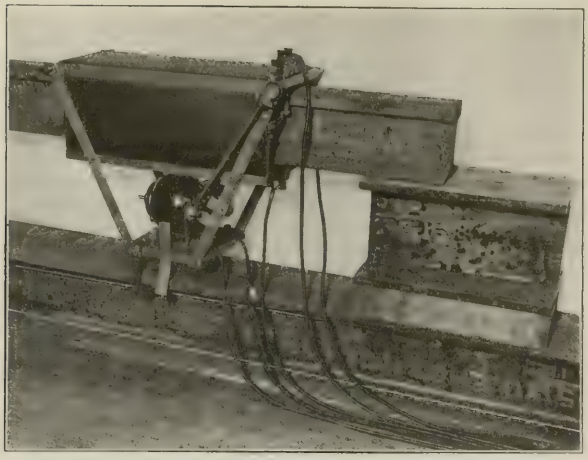

FIG. 1—SOLENOID FOR TESTING MAGNETIC LEAKAGE

mercial articles with considerable success. Experimental evidence already at hand shows that it is feasible to apply individual magnetic tests to many forms of tools, cutlery and springs. These tests are of such a nature that they may be carried out on a commercial scale. Rings and balls for ball bearings are now being tried out by this method with every promise of success. Steel rails, in spite of their size, lend themselves very readily to this method of examination.

Service Effects

Since the magnetic and mechanical properties of steel suffer changes with the lapse of time and under ordinary service conditions, the magnetic method offers a very promising means of examining, without destruction, the changes that develop during the life history of a structure. Some of the things to be looked for are the ordinary results of wear and tear. A good example of this is the mine or elevator cable. Such cables grow old and lose their usefulness or even become a source of danger due to the wearing away of the material, the breaking of strands, excessive strains, the development of a crystalline structure, etc. The causes of deterioration of a cable are so numerous and the possibility of disaster frequently so great that it is customary to replace an old cable by a new one while several years of usefulness remain in the cable. A proper magnetic test would keep the cable under surveillance at all times and make an autographic record.

A structure may fail by the development of flaws. For instance, a steel rail may render apparently satisfactory service for several years and finally develop a transverse fissure which results in a dangerous accident. Periodic examinations of rails which are under suspicion because of excessive duty or other causes may be made and we may thus detect the presence of such a flaw in an early stage of its development.

Another field which has not as yet been tried but for which the possibility has already been established is in the study of the state of stress of a given structural member. For instance, it may be desired to determine whether a given member in a bridge undergoes tension or compression during the passage of a train. The fact that steel suffers certain changes in its magnetic properties when put under tension and certain other changes when put under compression renders such a determination possible.

Routine Tests

The apparatus required and the procedure of testing depends to a great extent upon the nature and size of the material tested as well as upon the characteristic flaws to be expected. Apparatus for examining safety-razor blades is necessarily quite different, notably in size, from apparatus for the testing of steel rails. In the case of a lathe tool in which only the nose is hardened the examination differs from that of a locomotive driving rod which is more nearly uniform throughout.

Rails

If the testing of rails is to give a certainty of the quality of the material, it is necessary to test not only each rail but every element of the length of each rail. This may be accomplished by a double magnetic test. One part of the magnetic test will determine whether there are non-uniformities along the length of the rail. Since this test is based upon a determination of magnetic leakage it is referred to as the "leakage" test. The leakage test determines the homogeneity of the rail. Inhomogeneities, while they may not be due to dangerous imperfections, always cast suspicion upon the rail. Inhomogeneous rails should not be used in places where the highest degree of perfection is required. For instance, inhomogeneous rails should not be used on bridges, in tunnels, or where the traffic is heavy. Homogeneity in itself is not evidence of perfection. A rail may be quite uniform along its length and yet be an unsafe rail. Its dangerous nature may be due to improper chemical composition or to errors in the process of manufacture such as improper finishing temperatures or excessive cooling rates. To determine whether or not such defects exist requires a determination of one or more magnetic constants. These measurements may be made in some form of permeameter and in conformity with the nomenclature for similar tests on small specimens, we call this part of the magnetic examination the "induction" test.

Fig. 1 shows the general appearance of the leakage apparatus for rails. A magnetizing solenoid is moved

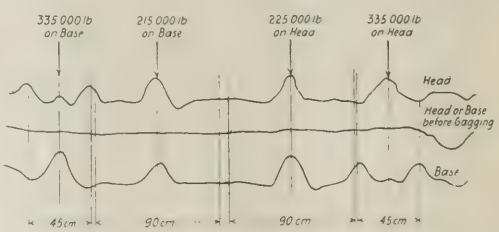

FIG. 2—LEAKAGE CURVES OF A RAIL BEFORE AND AFTER GAGGING

Vertical Arrows Indicate Position of Application of the Gag. Horizontal Arrows Indicate the Distance Between the Supports.

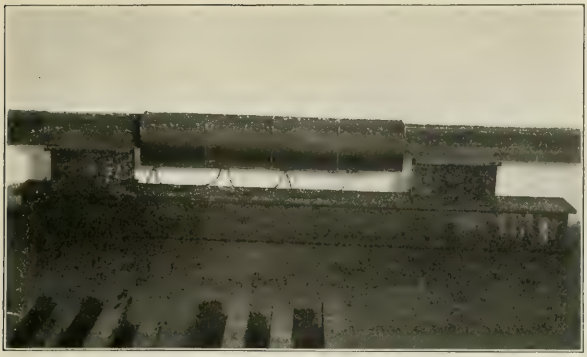

FIG. 3—SOLENOID FOR INDUCTION TEST

along the length of the rail. Any non-uniformity along the rail will cause a variation in magnetic leakage. This variation in leakage develops a small electromotive force which is approximately proportional to the degree and

It is one of a set of rails which was expressly prepared for this investigation. The rails as they left the hot bed were practically straight and therefore did not need to go through the gag press.

The middle record shows the normal record of a rail free from inhomogeneities. The irregularity in the curve at the right-hand end is due to the starting of the apparatus and therefore has no significance. From these curves several observations were made.

1. The rail before gagging shows a magnetic-leakage curve which is substantially a straight line.

2. Pressure applied locally so as to deform the metal produces a magnetic inhomogeneity at the point where the pressure is applied. This is true whether the pressure is applied on the head or on the base.

3. The extent of this local inhomogeneity depends upon the distance between supports. If the supports are far apart the strain seems to extend over the entire cross-section and seems to be greater on the side

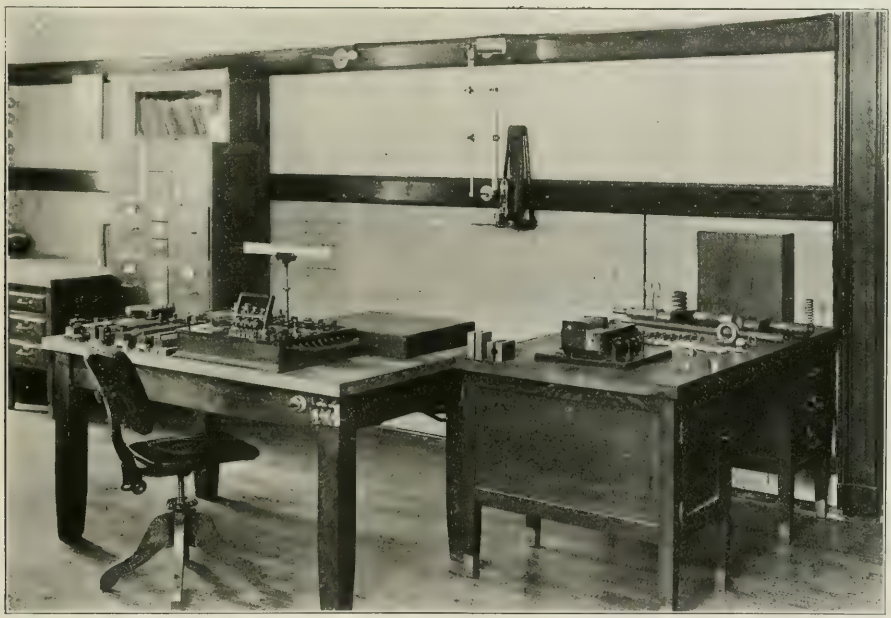

FIG. 4—MAGNETIC TESTING EQUIPMENT FOR SMALL OBJECTS

sharpness of the non-uniformity. A special recording voltmeter, not shown on the photograph, makes a photographic record of the magnetic inhomogeneities. This examination of a rail can be made in about one minute and excessive demands for skill and training are not made upon the operator.

Fig. 2 shows a set of magnetic-leakage records of a 105-lb. rail before and after gagging. This rail has the following chemical composition:

Carbon	0.68%
Manganese	0.98
Phosphorus	0.025
Sulfur	0.031
Silicon	0.144

of the rail opposite the point of application. If the supports are close together the strains are localized on the side on which the pressure is applied.

4. The strains set up by the supports depend upon the distance apart of the supports. If the supports are 90 cm. apart the magnetic effect of the supports is insignificant. If they are only 45 cm. apart this effect is considerable. In fact, the side of the rail on which the supports lie shows a magnetic inhomogeneity at each support which is greater than the corresponding inhomogeneity opposite the gag.

5. Other observations on other rails show that the

degree of magnetic inhomogeneity increases with the load applied by the gag.

6. Furthermore it is worthy of note that another rail from the same ingot which had been annealed showed a much less effect for the same gagging stress.

This ability of the magnetic leakage test to indicate the effect of gagging is of importance in view of the fact that many people consider that excessive gagging produces minute failures in the rail which are in effect potential transverse fissures.

The induction test is fairly simple. Fig. 3 shows the test rail and magnetizing solenoids in position. The accessory apparatus, which is similar to that required in induction measurements of small rods, is not shown. The most useful magnetic quantity is probably the coercive force. For the purpose of illustration we may give the coercive forces of two lots of rails of substantially the same chemical composition, made at the same mill, and differing only in their method of cooling. Four rails rolled in winter were from the first ingot which passed through the mill in starting the round for that particular date. Consequently these rails were the first upon the hot bed which was initially cold. Two other rails of substantially the same chemical composition were selected from a full hot bed and from the middle of a round rolled when the atmospheric temperature was 70 deg. Fahr. The averages of the coercive forces for a magnetizing force of 145 gausses were 10.30 gausses for the winter rails and 8.91 gausses for the summer rails. This difference of 1.39 is probably due in great part to the difference in the rate of cooling of the two sets of rails.

Tools

Fig. 4 shows a type of apparatus designed especially for the testing of drills, lathe tools, cutlery, etc. It is so arranged that the portion tested may consist of the major portion of the piece or it may be limited to the end portion.

A number of other pieces of apparatus suitable for magnetic analysis have been described more fully elsewhere.[3]

The coercive force is probably the most important test in the magnetic method, particularly in analyzing heat-treated specimens. An annealed steel may have a coercive force (the force necessary to neutralize residual magnetism) of 10, but this may be about 30 or 40 after the specimen is quenched. The coercive force will indicate differences in quenching temperatures as close as are measurable by means of the pyrometer. With rails it has not been found feasible as yet to apply the coercive force test, but dependence is placed on variations in permeability.

Commercial Magnetic Analysis

The fundamental fact that there is a definite relation between the magnetic and mechanical properties of steel is so well established that the successful application of magnetic analysis to commercial testing is assured. In any particular case the apparatus must be developed and operators trained. However, the difficulties presented are not excessive. Before shop methods of examination of any given product can be installed, a preliminary investigation must be carried out which involves five steps.

1. Magnetic data of representative material must be determined. Good, bad and indifferent materials must be examined and the data thus obtained correlated so that one may know what magnetic characteristics go with each grade of material.

2. From the mass of data thus obtained the most suitable magnetic criteria must be determined. In some cases any one of several magnetic constants may be equally satisfactory. In other cases only one specific constant may be used. Still others may require the combination of two or more magnetic constants.

3. Suitable apparatus must be designed. After the proper criteria have been determined the next step is to determine what type of apparatus is best suited for the particular material to be tested.

4. Limits of quality must be determined. Since the proper combination of speed, cost and accuracy may call for some slight deviation from the ideal theoretical considerations, the material to be tested must be examined by the final form of apparatus. From these data the final criteria of quality must be determined.

5. The final step of this preliminary investigation is the reduction of all the operations to mere routine, so that shop determinations may be made by an observer who is not necessarily an investigator.

It is not feasible to make an estimate of the cost of the testing equipment. However, it would not be excessive. The rail-testing apparatus shown could be duplicated for about $1,500.

Explosions of Picric Acid

By T. Sington

The process of making picric acid consists broadly in mixing carbolic acid with strong sulphuric acid, diluting this sulphonate with water and then running it slowly into nitric acid. The mixture is allowed to cool, when the crude picric acid crystallizes out and it is subsequently purified by re-crystallization. After thorough washing with water to remove all traces of free nitric and sulphuric acids, the material is whirled in a centrifuge to remove the bulk of the water. It is then removed to the drying shed where it is spread on glass steam-heated beds until all moisture is removed. The acid is then transferred in large open drums to the sifting room where it is ground, passed through a revolving screen, taken to the packing room, and packed in barrels of 100 pounds each. The large crystals which fail to pass through the sieve are reground in a crushing mill.

A suitable range of buildings for the manufacture of picric acid may consist of five buildings in which the wet processes of manufacture are carried out, and of four or more others in which the acid is dried, sifted, packed, and stored. These buildings ought to be separated from one another and from the "making" rooms by intervals of about 30 feet.

Explosions in picric acid factories are of rare occurence, but the destruction is then so thorough that there is considerable difficulty in tracing the cause. In opinions based on prolonged experience and on records ex-

tending over a long period of time, it has been considered that an explosion is impossible, provided the quantity of acid in any one building is limited to a moderate amount and that the acid is absolutely free from picrates. An entire factory may thus be regarded as constituting a fire risk, rather than an explosion risk, and consequently no distances beyond those necessary to prevent the communication of fire are necessary. Brick walls have therefore been deemed sufficient to protect life, inasmuch as explosions of picric acid have always been preceded by a fire of some minutes' duration.

In the case of an explosion of picric acid two separate and distinct questions may present themselves for discussion: First, the means by which the heat necessary for ignition is produced, and, secondly, why an ignition may develop into an explosion, instead of merely resulting in a comparatively harmless combustion. One of the manufacturing processes through which the material passes is of a nature which in connection with explosives is never entirely free from risk—this is the operation of grinding the larger crystals of picric acid which have failed to pass through the screen. While picric acid is by no means easy to ignite, when it occurs ignition is most likely in the grinding mill. Thus, the operation of grinding *dry* acid occasionally gives rise to fires, which may not be followed by explosions and which are readily put out, but the possibility of explosion is always present.

That the mere process of grinding is not necessarily dangerous follows from the immunity experienced during the operation of drilling out the primer space in the solidified charge of filled shells by means of power-driven steel drills, a method which has been very generally employed without the slightest accident. It does not necessarily follow that because picric acid may be safely ground in an iron mill, that nails, stones and similar hard foreign bodies which may accidentally find their way into the powdered material, are equally harmless. In fact, many fires in picric acid factories have been traced, after careful examination, to the presence of a nail in a grinding machine. Foreign bodies may find their way into the hoppers of grinding machines in a variety of ways, but it is contrary to all experience that an explosion should follow ignition. Should this occur, it would be necessary to reconsider all previous conclusions, and even to modify to a very considerable extent the conditions of manufacture.

A picric acid explosion of exceptional violence, causing widespread destruction of property, occurred in one of the manufacturing towns of Great Britain many years ago. After an exhaustive inquiry it was established beyond all possibility of doubt that the explosion was due not to picric acid alone, but to the presence of considerable quantities of lead and strontium compounds, which under the influence of heat and in contact with the melted picric acid led to the formation of lead and strontium picrates, both of which, and more particularly the lead salt, are not only in themselves violently explosive, but are capable of detonating picric acid in contact with them. Another explosion of picric acid occurred after a fire had been raging for nearly ten minutes; it was said to have been due to the formation of picrate of lime from the mortar in the roof of one of the buildings.

Textbooks for many years stated, on the authority of chemists of the highest standing, that when suddenly heated, picric acid will explode, but the actual experience of manufacturers furnishes a very emphatic contradiction to this statement, that pure picric acid when unconfined cannot be exploded by fire. Investigation of accidents such as the above also support this view, as do also the results of experiments instituted for the special purpose of clearing up this point. A case is recorded in which an iron vessel with a very small orifice and containing 25 lb. of picric acid was placed in a reverberatory furnace, when the acid burned away without explosion.

It has been found quite possible to explode picric acid by a blow, but the blow must be one of considerable force, if the material is cold. In fact, all experience appears to prove, as surely as negative evidence can be said to prove anything, that it may be taken as a practical impossibility for picric acid to explode without giving sufficient warning by fire to enable anyone in the vicinity to escape, and moreover a fire in its initial stages can be extinguished by water without much difficulty.

In the best planned picric acid factories the quantity of material which may be present in any one compartment is limited to 2000 pounds. When this limit is adhered to, and suitable sprinklers fitted up in every building liable to contain picric acid, the danger of a fire developing into an explosion is so slight as to be negligible. The process of dry grinding is also being discontinued, and some method of dealing with large crystals in a wet state substituted.

Manchester, England.

Control of the Chamber Process of Making Sulphuric Acid

At the winter meeting of the American Institute of Chemical Engineers held in New York, February, 1917, Andrew M. Fairlie of the Tennessee Copper & Chemical Company, presented an abstract of a paper on a method of controlling the chamber process. This was published in our issue of Feb. 1, 1917, p. 149. In the *Chemical Trade Journal and Chemical Engineer* for April 7, 1917, H. E. S. Cory discusses the same problem and says that the Fairlie analytical method, while excellent, does not, perhaps, go far enough. He says the important point, *i.e.*, keeping down the nitre consumption, has engaged the attention during the last few years of many technical managers in England, and has resulted, in some of the more up-to-date works, in the application of much more scientific methods of controlling the chamber process. The well-tried methods (*a*) of observing temperature differences at different points in the system, (*b*) noting the color of the gases, and (*c*) a combination of the two, are still very useful in conjunction with other means, though it must be admitted that in many works to-day these remain the only methods utilized.

To control a plant, and to work it economically on a scientific basis, many observations and tests are necessary, and in the larger and more modern of our works, where able technical control is available, the standard has been greatly improved.

One great point, frequently formerly and indeed often to-day practically ignored, is the necessity for maintaining an adequate supply of atmospheric oxygen in the system, this being regulated in conjunction with a com-

paratively rich burner gas. A series of daily tests of the burner gases for SO_2, SO_3 and oxygen are very necessary, and often considerable fluctuations are to be found, particularly in the case of hand-worked burners, the variations being due largely to working operations from time to time. Most particularly on sets working with a low chamber space, the need for a good supply of atmospheric oxygen is very essential, since otherwise the nitre will supply the deficiency, thereby causing loss of efficiency with regard to the full utilization of the nitrous gases, and, incidentally, raising the amount to be added at the nitre ovens.

Granted an adequate supply of inlet oxygen in the burner gas (9 to 10 per cent is a good figure when using pyrites), a rich SO_2 is also to be aimed for, say 6½ to 7½ per cent, and at the same time a sufficiency of oxygen at the exit should be available. With a "tight" set this latter figure should not fall below 5 per cent, and to a large extent will regulate the composition of the burner gas itself.

The percentage of total acids and oxygen in the gases leaving the Glover tower, but before entering the first chamber, is another useful test, as it demonstrates the amount of work done by this tower and is an aid to the most effective working of the Glover. Again, the functions of the Glover tower are to be constantly observed, so that one obtains (1) perfect denitration, (2) effective gas admixture and cooling, (3) satisfactory concentration of acid, (4) efficient cooling of the acid leaving the tower, and (5) free gas passage through the tower.

The temperatures of the gases at the front and back ends of the first chamber should be noted at regular intervals, and water gages placed at various progressive points in the system serve to show the speed of the gases.

"Drips" placed at frequent intervals on all the chambers indicate the strengths of acid being made, and should be compared with the strengths of the "bottom acids" in the chambers, which comparison varies accordingly as water sprays, steam, or a combination of both be used, and depends somewhat upon the position and shape of the "drips" or drip-catchers. The "bottom acids" should be tested frequently for strength and nitrosity, and the drips occasionally and qualitatively for nitrosity.

It is highly desirable that the acid in the chambers be thoroughly circulated, so that all acid is drawn off at the front end of the leading chamber after traversing the length of all the chambers in the system and always moving in the opposite direction to the gases. By using connecting chutes alternately at opposite ends of the various chambers such a circulation can be easily carried out, and intimate contact between acid and gases is established, fresh acid surfaces continually presenting themselves. Also, the leading chamber may be used as a "denitrating" chamber, so that all acid run on from the chambers is free from nitrous compounds. This is not essential, and often not advisable where the whole or a large part of the acid make is concentrated by the Glover tower.

Any nitre contained in the "bottom acid" flowing round through this leading chamber is thus evolved, and, intermingling with fresh gases from the Glover tower, proceeds through the system again.

At times acid may be again dispatched to the last chamber after having worked round, in order to come forward again, thus maintaining an active acid circulation continually. With acid continually on the move, a nitre content to a reasonable extent frequently helps the workings, and at the same time does not damage the lead materially, as no stagnant acid is present in the system.

The acid distribution on the tower tops requires regular attention, and constant flows, particularly on the Glover tower, should be maintained. Any shortage or excess of nitrous vitriol in the circulating acids can be remedied by adjustment of the absorber tower feeds, the Glover feed never being reduced for this purpose.

As oxygen is required in the absorber towers to insure correct chemical reactions, gas tests taken between the last chamber and first absorber are most useful. The SO_2 at this point should not exceed 0.1 to 0.2 per cent, and oxygen should be 5 per cent or more, these figures applying to sets burning pyrites. However, a rise in these figures does not necessarily demonstrate a deficiency of nitre in the system, but may be due to excessive draught, which is easily righted.

Tests of the gases for total acids, *i.e.*, SO_3 and SO_2 combined, together with oxygen, may be taken occasionally at the end of each chamber, and give the operator an indication of the comparative work done by each chamber in the set.

On the absorber towers cool acid is essential, and should not exceed 90 to 100 deg. Fahr., while a minimum strength of 140 deg. Tw. is desirable. Where two absorbers or a series are working, intelligent variation and adjustment of the flows render absorption the more satisfactory.

In a well-regulated system one important aim is that of maintaining a good "nitre circulation," and to this end the acid flowing down the Glover should be frequently measured at the inlet, the nitre contents being tested simultaneously. This enables the circulation of nitre going forward from the Glover tower to be calculated in pounds of $NaNO_3$ per hour or similar convenient form. An efficient and constant nitre circulation obviously is to be aimed for, as the nitre added at the pots is thereby reduced.

Nitrosity tests of the acids leaving absorber towers should be taken thrice or more daily, and the gas "smell" test is very useful. The mode of operating the latter is as follows: The operator takes a sample of chamber gas into a small hand aspirator consisting of a rubber bulb fitted with a glass tube jet at a place not too far back in the system. A little experience enables the operator to judge how his chambers are working by differences in the "smell" of the gases, and any variation or tendency toward "souring" is checked in good time by an extra charge of nitre at the pots.

Exit tests may be done with advantage about thrice daily (express as grains SO_2 per cubic foot of gas), and a good working figure should usually not exceed 1.8 to 2 grains. As the "burner gases" at certain periods come forward into the chambers in "flushes," the following method of applying the nitre at the pots is recommended as being most economical. A minimum amount of nitre is added each hour at the pots, and this should be accurately weighed on a scale, and at intervals this amount is raised—*i.e.*, if 10 lb. per hour is being potted, perhaps every three or four hours, 20 lb. would be added in order to counteract the gas "flushes." This is undoubtedly more economical than using a regular and heavier

charge of nitre hourly, and the "smell" test is of great utility at this point. With the latter method a continuous nitre saturation is present, and this state of affairs is certainly not beneficial to the leadwork, as, on the contrary, occasional "souring" of the gases has, if anything, a good effect upon the leadwork.

A fan worked by direct-coupled motor and equipped with variable speeds should be fitted between the two absorbers, and the speed taken at regular intervals. A convenient speed for most systems is 300 to 400 r.p.m. on the fan.

A control damper fitted in the draft pipe between the last chamber and the first absorber is very suitable, and the sizes of the draft pipes should gradually diminish throughout the system. Inspection doors fitted into the chamber curtains at a height of some 3 ft. or 3 ft. 6 in. above floor level enable the operator to observe the color and movements of the gases, and are useful when acid samples are required. These doors should preferably be at an angle of 45 deg. to the lead curtain. The speed or draft is an important factor requiring frequent observation.

The control of the burners or furnaces is the most important part of the system; the control of the burners largely depends upon the analysis of the "burner gases," but painstaking examinations of the burners themselves are necessary to insure good and regular chamber workings.

By adopting such means of control as described, he states that a most economical nitre usage with a maximum make of acid should be obtainable. A maximum figure for "nitre circulation" should be decided upon for each set, as too much nitre going forward, while reducing the amount to be added at the pots (to make good chemical and mechanical losses), has a detrimental effect upon the chamber leadwork. With a reduced chamber space, however, the nitre circulation requires usually to be raised, and this undoubtedly largely contributes to the increased wear and tear. Where several sets are working together or adjacently, as in many of the larger and more modern works, these methods of control should prove very useful. Where nitric acid is used the same rules apply, though nitre may also be used for the purpose of counteracting gas "flushes" where practicable.

Synopsis of Recent Metallurgical and Chemical Literature

Japanese Industries

Current Chemical News from Japan.—In Vol. 1, No. 4, of the Chemical Technology are given several pages in English of current news from Japan, as in previous numbers. In regard to the iron and steel industry it says the production in 1914 was 303,407 tons and the consumption 1,300,000 tons. Recently a great many new companies have started up and old ones have so expanded that the production has increased enormously. The available ore is given as 50,000,000 tons of magnetite, 4,293,000 tons of hematite, 494,000 tons of brown iron ore, and 226,000 tons of sand iron. This will not last long and Japan is investigating in Manchuria, Korea and inner China for further supplies.

Gelatin and Glue.—In regard to gelatin and glue the following is of great interest:

"The importation of gelatin and glue had increased its amount to a million yen, and the quick development of our paper, spinning, cloth-finishing, sweets-making and match industry has demanded more and more importation. But the manufacturing of the gelatin and glue at home has also quickly developed. The research work has been also established at Tokyo, Osaka, Wakayama, Nara and Tokushima.

"Among the new establishments, the Takasago, Kogyo Kabushiki Kwaisha is the largest, which is going to produce 10,000 lb. gelatin and 15,000 lb. glue monthly. This amount will well fulfill the home demand. Furthermore, the Osaka-Alkali Company is going to start the manufacturing, while the Mitsubishi Company is enterprising a big firm at Kakogawa. These big firms will certainly bring a big surplus against our home trade and we must expect certain panic in a near future unless they will find a proper market."

Chemical Exhibition.—An exhibition of chemical products is being arranged and it is hoped to open same in October.

Wood Distillation.—Prof. Dr. Tamara has issued a report as follows:

Total demand of 80 per cent Ca-acetate per month is:

For glacial acetic acid	110,295	kwan.
For acetone	61,250	"
Total	171,545	"

Total production of 80 per cent Ca-acetate at home is:

The Nippon Acetic Acid Co., Shiwobara Works	13,800	kwan.
Kabafuto (Sagalin) Government Works	8,280	"
Tottori-ken, Kondo Works	3,600	"
Chichibu Distillation Works	3,200	"
Wakayama Province	20,000	"
Saëtama Province	5,000	"
Others	7,000	"
Total	60,880	"

This output is only 36 per cent of the demand, the rest, 64 per cent, being imported. On the other hand, the demand of glacial acetic acid at rubber districts of Oceania has lately enormously increased.

Crude methyl alcohol is also much required, which is converted into 99 per cent pure methyl alcohol, 95 per cent spirit, 90 per cent spirit. Among them, the pure methyl alcohol is much consumed for the manufacturing of formalin. The total demand of formalin at home is about 1,500,000 lb. annually, which corresponds to about 1,250,000 lb. 99 per cent methyl alcohol, or 3,125,000 lb. crude methyl alcohol. That is, we require about 260,000 lb. crude alcohol per month. At present crude alcohol is produced monthly as the following:

The Nippon Acetic Acid Co., Shiwobara Works	18,000	lb.
Kabafuto Government Works	15,000	"
Tottori-ken, Kondo Works	3,600	"
Chichibu Works	1,000	"
Total	37,600	lb.

This amount is only 14.5 per cent of the total demand. We want further wood tar, not only for the producing of formalin, but for the manufacturing of creosote, guiacol, guiacole carbonate, thiocole.

Refractories

Hot and Cold Sizes of Firebricks.—In the *Iron and Coal Trades Review*, June 15, 1917, the results are given of experiments by J. W. Mellor, on hot and cold sizes of typical firebricks. The article is included in a report of the Refractory Materials Committee of the Institution of Gas Engineers, made at its meeting in London June 5. The experiments were carried out at the County Pottery Laboratory, Stoke-on-Trent, and formed one of a series on refractories.

The measurements on the whole brick were made with Coppée's apparatus. Two cuts are made in the brick; each cut is intended to hold a pointed platinum wire. The two saw cuts are arranged so that the wires fit tightly. The distance apart of the tips of the wires is measured while the brick is cold (15 deg. C.) by means of a cathetometer provided with an invar scale. The brick is heated in a furnace to the desired temperature, and, by means of suitable apertures in the furnace, the distance apart of the wires is measured again. The results are indicated in Table I.

Table I

Type of Brick	Distance Between Platinum Wires. Before Firing. Cms.	Distance Between Platinum Wires. After Firing. Cms.	Percentage Expansion	Linear Co-Efficient of Thermal Expansion
Silica brick	17.95	18.05	0.56	0.0000048
Firebrick	18.78	18.87(5)	0.51	0.0000044
Firebrick	20.31	20.45	0.69	0.0000059

Firebrick	18.29	18.41	0.66	0.0000057
Firebrick	18.71	18.84	0.70	0.0000060
Firebrick	19.41	19.53	0.62	0.0000053
Red silica brick	19.29	19.46	0.88	0.0000076
Silica brick	18.27	18.41	1.77	0.0000066
Silica brick	18.52	18.78	1.40	0.0000121
Silica brick	18.85	18.94	0.48	0.0000041
Firebrick	18.53	18.66	0.70	0.0000060
Firebrick	18.84	18.98	0.74	0.0000064
Firebrick	18.89	19.06	0.90	0.0000177
Firebrick	19.50	19.70	1.03	0.0000088
Firebrick	18.93	19.07	0.74	0.0000064
Magnesite brick	18.39	18.66	1.47	0.0000126

If the brick is imperfectly burned, there is superposed on the effects of thermal expansion an after-contraction or after-expansion. In consequence, in the former case the results are too small, and in the latter case too large. Still further:

(1) The brick does not contract to its original volume on cooling. The difference between the cold sizes of the brick before and after firing shows the magnitude of the after-contraction or after-expansion, when the brick was heated under conditions of the experiment.

(2) In all cases of after-contraction (or, *mutatis mutandis*, after expansion), the brick may show a smaller volume at, say, 1,180 deg. C. than it does at, say, 1,060 deg. C. This shows that the effects of thermal expansion are altogether masked by the after-contraction. Thus:

Distance of wires at	15° C.	18.72 cm.
" "	1,060° C.	18.80 cm.
" "	1,180° C.	18.75 cm.

It was only when the whole of the cold and hot measurements were under consideration and were being extended to different temperatures that the duel character of the phenomenon was discovered; and it has made the Committee suspect these and other measurements of the coefficients of thermal expansion of refractory materials at high temperatures—unless it can be demonstrated that the results are not affected by the error under consideration.

These measurements also show that the coefficient of expansion of fireclays and of silica bricks decreases with rise of temperature. Thus, in two cases:

Silica Firebricks.

	I.	II.
From 15° to 940° C.	0.0000069	0.0000081
From 15° to 1,180° C.	0.0000060	0.0000060

Silica Firebricks.

From 15° to 940° C.	0.0000051
From 15° to 1,180° C.	0.0000064

It will be observed that the coefficient of thermal expansion represents the average increase in length which a break undergoes when unit length is heated 1 deg. C.; so that a 9-in. brick with a coefficient of 0.000005 will be 9 $(1 + 0.000005 \times 1{,}200)$, or 9.054 in. long at 1200 deg. C. Otherwise expressed, a brick $2\frac{1}{2}$ in. thick when cold will be $2\frac{1}{2}$ $(1 + 0.000005 \times 1{,}200)$, or 2.515 in. thick at 1,200 deg.; or, neglecting the jointing cement, sixty-six bricks piled one on top of the other would expand 1 in. when heated to 1,200 deg.

After-Contraction or After-Expansion of Firebricks in Oxidizing and Reducing Atmospheres.—Another investigation by the same author dealt with the above subject. It is well known that ferrous iron has a far greater fluxing action than ferric iron, so that the contraction of a brick fired under reducing conditions will probably be greater than when fired under oxidizing conditions, providing no bloating occurs. Nearly all firebricks are burned under oxidizing conditions. It therefore appeared of interest to find the difference in the results obtained in the specification contraction test when conducted under oxidizing and under reducing conditions. Some measurements are given in Table II.

C signifies contraction, *E* expansion; the specimens marked with an asterisk were fired at cone "12" for two hours, and the others at cone "14." See standard specification.

These results show a general tendency for silica bricks to give a less expansion in a reducing atmosphere than in an oxidizing atmosphere; and for (fireclay) firebricks to give a greater contraction in a reducing than in an oxidizing atmosphere. This result might have been anticipated, because it is in agreement with the much greater fluxing effect of iron in a reducing than in an oxidizing atmosphere.

Table II

Type of Brick	Percentage After Expansion or Contraction (Means of Duplicates). Oxidizing Atmosphere		Reducing Atmosphere	
Silica brick, unusually fine grained..	0.44	C	0.77	C
Silica brick, high in "iron"	0.58	E	0.48	E
Firebrick	0.21	E	Nil	—
Firebrick	Nil	—	0.33	C
Firebrick	1.12	C	1.27	C
Silica brick	0.20	E	0.13	E
Silica brick	0.13	E	0.12	E

The magnitude of the fluxing effect induced by the reducing atmosphere depends upon a number of factors. For example: (1) It depends upon the strength of the reducing atmosphere; that is, on the proportion (and kind) of reducing gases in the given atmosphere; (2) it will also depend upon the rate the gases penetrate into the interior of the brick, and this in turn depends upon the character of the superficial skin and on the

porosity of the brick; and (3) on the time and temperature the brick is bathed in the reducing atmosphere. It is, therefore, difficult to get comparable results with the contraction test under reducing conditions. This agrees with some previous results obtained by determining refractory tests under reducing and oxidizing conditions.

For similar reasons, a neutral (or slightly oxidizing) atmosphere was prescribed for the refractory test, until further experiments showed how this source of variation could be eliminated. It would be unwise to prescribe a test which gives variable results. The author expects that further experiments on this subject will be ready for the next annual report; meanwhile, it is recommended that the "contraction test" be conducted like the refractory test—that is, in as nearly a neutral atmosphere as practicable.

Recent Metallurgical and Chemical Patents

Sintering

Apparatus for Roasting and Sintering Ores.—ARTHUR S. DWIGHT of New York, N. Y., has patented

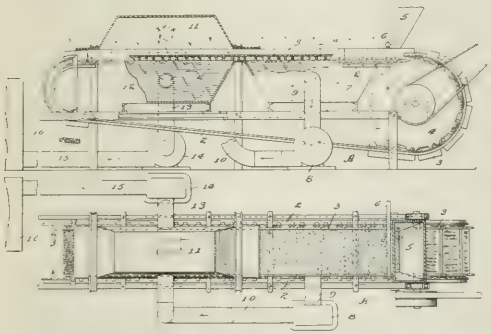

FIG. 1—DWIGHT SINTERING MACHINE

a new sintering machine which is illustrated in Fig. 1. The improvement in this machine over the Dwight-Lloyd machine consists in eliminating the waste of the fine sulphur which is found in gases coming off from some sulphide ores during the operation of the last-named machine. This sulphur is in a very finely divided state and ignites on the gases issuing into the air. It is the aim in this machine to convert the elemental sulphur escaping from such ores into sulpur dioxide, thus increasing the amount of this gas in the gases coming from the machine. This is accomplished by constructing the apparatus in such a way that the ignited sulphide ores may be repeatedly treated by the same volume of air in separate units, i. e., the air used to treat the first unit of ignited ore is passed to a second body of ore and supplying thus the oxygen required for the roasting or sintering of said second body of material. In this manner the patentee has been able to increase the sulphur dioxide content of the gases to 9 per cent, and it is his belief that the proportion of dioxide of sulphur may be increased still more. (1,215,637, Feb. 13, 1917.)

Agglomerating Flue-Dust and Fine Ores.—A patent was granted to WILHELM SCHUMACHER of Berlin, Germany, for a new method of roasting or sintering finely divided ores and flue-dust. The principle employed consists in incorporating in the form of small, permanent, ball-like or egg-shaped briquettes the finely divided particles of such fine ores whose sintering and melting points are relatively close together, then exposing such briquettes to a temperature between the sintering and melting temperatures of the ores and maintaining continual movement of the briquettes while in the sintering or roasting zone. (1,222,893, April 17, 1917.)

Nickel

Treatment of Nickel Ores.—A patent was granted to FREDERIC A. EUSTIS of Milton, Mass., for the extraction of nickel from its ores by a wet method. The ore is first subjected to heat treatment, preferably a sulphatizing roast. This is done with the intention of converting the nickel into a soluble form. If not enough sulphur is present in the ore as such, 5 to 10 per cent of its weight of sulphur-bearing material such as pyrite should be added. Roasting takes place at about 460 deg. C. and is continued for approximately 4 hours. It is also possible to moisten the ore with the least possible amount of sulphuric acid and then roast at 500 deg. C. for a considerable length of time. The roasting converts a large proportion of the nickel present into the soluble sulphate. A considerable amount of alumina is also converted into the sulphate, while a relatively small amount of the iron is converted into sulphate. The heat treatment also affects the amount of iron which will be taken into solution. Little soluble iron is formed. The roasted product is then leached with dilute sulphuric acid, or with a solvent consisting of water containing one-half of 1 per cent of sulphuric acid and 7 per cent of hydrochloric acid. The solvent should be applied hot (100 deg. C.), so as to prevent as much as possible the solution of iron salts.

The solution containing the nickel and some alumina and iron, is then preferably passed through a trommel containing pieces of limestone. The trommel is slowly rotated and the solution becomes neutralized and calcium sulphate is precipitated. After neutralization has been accomplished the solution should be drawn off and received in another receptacle containing limestone. This will primarily precipitate the alumina and near the end iron will come out. When this point is reached, the solution is again drawn off and conducted into a vessel containing soda ash or some other material forming soluble sulphate. The precipitated nickel may be sold as such or re-treated with a suitable solvent such as sulphuric acid or a solution of ammonium or potassium sulphate in sulphuric acid to form an electrolyte from which the nickel as such may then be deposited. (1,212,334, Jan. 1, 1917.)

Rare Metals

Method for Treating Vanadium-Bearing Ores.—ROYAL S. DAVIS of Newmire, Col., was granted a patent for an improved method of treating vanadium-bearing ores and particularly for the recovery of values ordinarily rejected when treating the ore preparatory to reduction. The ores are subjected to a chloridizing roast in a reverberatory furnace to convert the vanadium into a vanadate. The roasted ore is then leached and the residue left, containing recov-

erable amounts of vanadium in the form of V_2O_5, is then treated for the recovery of the vanadium content.

The gases coming from the chloridizing furnace are scrubbed and cooled by passing them in a coke tower. The water trickling over the coke collects and absorbs the SO_2 and Cl in the gases. This solution then is applied to the ore residue and it is found will convert the V_2O_3 to a soluble vanadate, which in turn is then leached. It is claimed that the unscrubbed gases may be applied directly to the moist ore, giving satisfactory recoveries. Ten to fifteen per cent greater recovery is claimed for this method over the ordinary water leaching process. (1,223,567, April 24, 1917.)

Alloys

Aluminium Alloy and in Articles Made Therefrom.—A patent under the above heading was granted to Albert W. Morris of Springfield, Mass. The invention relates to an aluminium alloy and to castings and forgings made therefrom, the object being to provide an alloy which will permit of the full chilling effect of the mold or die, will reduce the shrinkage of the castings or forgings, overcome the danger of cracking, increase the tensile strength and the elongation properties. The alloy may consist of aluminium and iron alone, or it may contain zinc, copper, nickel, cadmium, magnesium and manganese, besides the aluminium and iron. A certain proportion of iron, properly alloyed with the aluminium will, according to the inventor, produce the claimed effects. Where the alloy contains other metals, the percentage of aluminium should not be less than 70 per cent of the whole, and the percentage of the iron present should not be less than from 1 to 6 per cent. Care should be exercised to keep the silicon content as low as possible. The iron may be introduced in the form of ferro-aluminium, ferro-zinc, ferro-copper or the like, or it may be introduced in the metallic state in form of filings or chips, or it may be derived from the furnace pot or crucibe in which the aluminium is melted. The invention, it is claimed, is of especial importance in the manufacture of fuses and detonators for explosive shells as it creates a great density in the product and prevents leakage through it of the gases, which would cause premature explosion of the shell. (1,227,174, May 22, 1917.)

Gases

Electrical Treatment of Hydrocarbon Gases.—A process of treating gases, such as illuminating gas with a high-tension electric discharge, is patented by J. G. Davidson and R. W. Ford of Vancouver, B. C. By subjecting a gas or vapor containing a hydrocarbon or hydrocarbons, such as illuminating gas, or other gas produced by the destructive distillation of coal or petroleum, or other methods of manufacture or production, to the action of a high-tension electric discharge under certain conditions, a considerable change may be effected in the final product, indicating an increase in the proportion of fixed gases in the total final product and an increase in the volume of gas produced. An important object of the invention is to increase the percentage of fixed hydrocarbons in illuminating or similar gases, by breaking up condensable constituents into substances of less molecular weight and less condensability. Another object incidental to the above is to increase the volume of gas produced. (1,229,042, June 5, 1917.)

Platinum Substitute

Platinum Substitute.—Alloys of palladium, silver and cobalt are patented by Hugh S. Cooper of Cleveland, Ohio, and assigned to the Electro-Metals Products Co. of Cleveland, Ohio. One composition stated to be a successful platinum substitute for electrical purposes consists of 70 per cent silver, 25 per cent palladium, and 5 per cent cobalt. Platinum may be substituted for the palladium with good results, and nickel for the cobalt. The alloys are adapted for use in coils, magnetos and all vibrating instruments. (1,229,037, June 5, 1917.)

Iron and Steel

Low-Carbon Ferromanganese.—A method of making ferromanganese containing less than 1 per cent of carbon is patented by Ernest Humbert of Niagara Falls, N. Y. The reduction of the carbon is affected by treating commercial ferromanganese containing up to 6 per cent of carbon with manganese oxide. An electric furnace of the Heroult type is used. A specific example of the process is given as follows: "Take 2000 lb. of ferromanganese containing 6 per cent carbon. This is 120 lb. of carbon, and requires 160 lb. of oxygen. This amount of oxygen will be found in 710 lb. of manganese oxide (MnO). If the reaction were perfect there would result 2000 — 120 + 550, a total of 2430 lb. of ferromanganese containing no carbon. These calculations are for pure oxide of manganese. As commercial manganese ore is never pure MnO, the calculations must be made on the MnO content. Also a certain excess of the oxide must be used, about 10 to 20 per cent over the theoretical amount, because a certain amount of the oxide remains in the slag. The ferromanganese is introduced into the furnace either cold or molten. If cold, it is first melted in the electric furnace. The manganese oxide is then added. Probably the best voltage to use is 50 volts at each arc, but it may be varied according to the design of the furnace and other considerations. The quantity of current, amperes, should be sufficient to keep the mass at the temperatures stated. A test of the metal will show a reduction of carbon by the appearance of the fracture, being less crystalline and more like steel than in high-carbon ferromanganese. Also the specimen will be less brittle the lower the carbon.

The low-carbon ferromanganese produced by this method is stated to be of a special utility in the making of what is commercially known as manganese steel containing a comparatively high percentage of manganese, ordinarily from 10 to 15 per cent. (1,228,925, June 5, 1917.)

Welding Scrap Nickel Anodes

The practice of utilizing every pound of nickel anodes for service by welding the scraps together is effecting a considerable saving in many plating departments and establishments, and is of special importance at the present time. An account of experiments made by the Prest-O-Lite Co. of Indianapolis, Ind., was given in our issue of July, 1915, page 453.

Until recent years, many firms sold their anodes as scrap for want of a thoroughly satisfactory method

of utilizing them. This was always a source of considerable loss to platers, for the scraps often represent a considerable portion of the original anodes and their junk value is less than one-half their original cost. By welding the scraps together, by the oxy-acetylene welding process, every pound of the costly metal is utilized for plating purposes.

The practice of welding scrap anodes is usually as follows: The worn anodes, as they are withdrawn from the tanks, are turned over to some workman who handles the welding. A scrap of suitable size and shape is selected as a "hanger" and other scraps are "tacked" to it by welding until the desired size and weight are secured. The "tacking" consists of melting the scraps, at the point of welding, by the heat of the oxy-acetylene flame, allowing them to run together or "fuse" into one piece. The "tacking" of a joint requires but a moment as the temperature of the oxy-acetylene flame, which is approximately 6300 deg. Fahr., causes the metal to "fuse" quickly.

No flux is used—the metal simply runs together and where necessary another piece of scrap nickel is used as a filling rod.

The oxy-acetylene flame is also used to remove the brass hooks from the scraps, the solder melting rapidly, leaving the pure anode to be welded.

Several other methods of utilizing scrap anodes have been tried in the past, but with uncertain results. The method of fastening them together by means of rivets and similar methods are seldom thoroughly dependable because of uncertain conductivity. It is impracticable for anyone but the manufacturer to remelt and repour anodes, because in so doing the composition is changed. An advantage claimed for welding the scraps together is that the original composition is not changed and the fused joints insure conductivity equal to that of new anodes.

Another advantage claimed is the fact that no skill or experience in the art of welding is required to weld up scrap nickel anodes. Any workman of average intelligence can do the work without previous knowledge of the process.

The accompanying illustration shows the welding of scrap anodes by the Prest-O-Lite process of oxy-acetylene welding. Welded anodes are seen in the foreground.

OPERATOR WELDING SCRAP NICKEL ANODES

American Sulphur Company Rapidly Expanding

The accompanying illustrations, Figs. 1, 2 and 3, show the pumps, foundations and buildings of the Freeport Sulphur Mines located at Brazoria County, Texas, at the mouth of the Brazos River on the Gulf of Mexico, and are the property of the Freeport Sulphur Company. The discovery of the sulphur deposit was accidentally made while prospecting for oil, and its location is believed to be unique as being the only mines situated at tide water and having a deep-water harbor immediately adjacent from which shipments by vessel are made.

It may be stated that the great sulphur deposit underlies "Bryan Heights," one of the domes which dot the coastal plain. It has an area of about 500 acres, and its crest is but 28 ft. above mean low tide. The suplhur-bearing horizon lies many hundred feet under the surface, surmounted by a limestone cap, the sulphur occurring in pockets and veins in a porous gypsum formation heavily loaded with water, as it is below sea-level. To recover the sulphur, millions of gallons of boiling water are forced into the formation under heavy pressure, searching out the sulphur and freeing it from the rock which contains it. In its melted state it is pumped by compressed air to the surface, where it is forced through piping to immense storage bins, where it congeals and builds up huge blocks of solid sulphur 99½ per cent pure.

It is of interest to note that the largest oil-burning steam boiler plant in this country has been established at the mines to recover the sulphur. The experimental plant, known as plant No. 1, was built in 1912, and has a capacity of 3000 boiler-horsepower. Plant No. 2 was built adjoining plant No. 1 in 1914, and has a capacity of 4000 boiler-horsepower. Plant No. 3, finished this year, and plant No. 4, now under construction, are situated on the other side of the mound and have a capacity of 8400 horsepower each, making

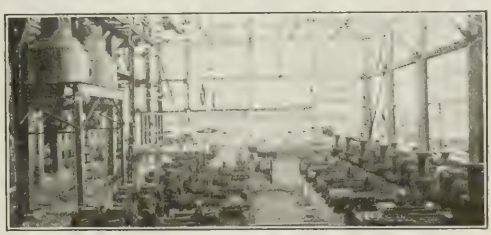

FIG. 1—FREEPORT SULPHUR COMPANY, FREEPORT, TEX. PUMPS IN PLANT NO. 3

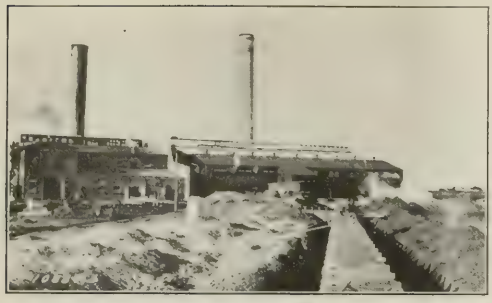

FIG. 2—FREEPORT SULPHUR COMPANY, FREEPORT, TEX. PLANT NO. 1 AT LEFT, NO. 2 AT RIGHT

a total installation of 23,800 horsepower. The buildings are constructed of steel and corrugated iron on concrete foundations. Fuel oil for boiler purposes requires continual tank steamer service from the Mexican oil fields, and the Freeport Sulphur interests own and operate their own tank line.

It may be mentioned that the boiler water supply is obtained from a series of wells, pumped by air compressors, and is stored in two reservoirs. The mine water supply is obtained from the river through a canal 3½ miles long, and is pumped into two separate reservoirs. Both mine and boiler water are treated with calcium hydrate to remove scale-producing salts before going to the reservoirs, where the precipitation takes place. The precipitated sludge is periodically pumped out of the reservoirs by a hydraulic suction dredge. A day's water supply is pumped and treated in 8 hours, and 7000 lb. of calcium hydrate are daily used in the process.

Electric power is used to great extent, the pumps being electrically driven. The power equipment consists of two 250-kw., 2200-volt generators, and one 500-kva., 22-volt generator. This power plant transmits current to the town of Freeport for lighting and power as well as to the pumping stations. A 4-ton ice-making plant and water-purification plant furnish the works with all ice and drinking water required. All excess steam about the plant is used for heating water. After scale-producing salts have been removed from the boiler water there still remain salts which cannot be removed by chemical treatment and cause foaming and priming in the boilers.

It is claimed that the concentration in the boilers is kept within safe limits by continuously blowing them off, and special arrangements are made for recovering the heat from the blow-off water. At the water's edge a large timber-loading dock was built. Sulphur dynamited at the storage bins is loaded by means of two locomotive cranes with clamshell buckets into 50-ton cars and carried to the dock.

The storage tracks for full and empty cars at the dock are so graded that cars are delivered by gravity to the foot of the incline leading to the elevated dock structure and empties returning from the dock are delivered by gravity to the empty storage tracks, thus doing away with the service of a switching engine. The loaded cars are hauled one at a time by a barney car operated by a 200-hp. winding engine up the 15 per cent incline to the top of the elevated dock where they discharge the sulphur into chutes leading directly to the hold of the vessel. The empties are returned three or four at a time down the incline by the same means. A 3000-ton ship can be loaded between tides.

FIG. 3—FREEPORT SULPHUR COMPANY, FREEPORT, TEX. PLANT NO. 3 IN BACKGROUND, FOUNDATIONS FOR PLANT NO. 4 IN FOREGROUND

Operation of a Temperature Regulator

The enormous pressure developed when oil is heated in a filled metal cylinder is utilized in the Sarco temperature regulator, made by The Sarco Company, Inc., of New York City. The regulator operates gas, steam or water valves and can be used for tank or atmospheric control. Referring to the illustration, Fig. 1, the oil cylinder communicates through a pipe with another cylinder in which there is a piston, the entire system being completely oil filled. The piston in the piston cylinder actuates a valve. If the oil cylinder is immersed in a tank containing the fluid, temperature of which is to be regulated and that tank is heated, say by a gas flame, the supply of gas to which is regulated by the supply valve, the mode of operation is obvious. When the temperature of the tank liquid rises, heating the oil in the oil cylinder, the expanding oil pushes the piston outward in its cylinder and closes down the supply valve, thus reducing the gas flame. If on the other hand the tank temperature falls, the oil in the cylinder cools and contracts, thus allowing the piston in the piston cylinder to go back under the influence of a spring (not shown) opening the supply valve and thus turning the gas flame higher.

Were the piston in the piston cylinder of the conventional type, trouble would ensue because, obviously, successful operation requires that the oil system be absolutely tight, the escape of even a minute quantity of oil altering the whole setting. In other words, it is imperative that the piston packing be leak-proof, capable of withstanding the enormous pres-

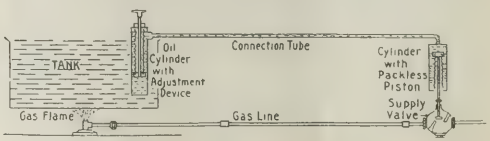

FIG. 1—DIAGRAM OF REGULATOR AND CONNECTIONS

sures which are involved, and at the same time frictionless. The Sarco Company has developed a spirally corrugated tube, a section of the same being hermetically attached to the outer surface of the piston at one end, and to the inner skirt of the oil cylinder at the other end, as shown. This tube will withstand pressures in excess of 3000 lb. per square inch.

While the regulating system as so far described is complete and would be commercially operative, it is naturally desirable to add some means of adjusting the temperature setting. This is accomplished by having the connection tube issue from the side of the oil cylinder instead of from the top, and then inserting from above a piston which can be adjusted up or down by a regulating screw. When adjusted downward the temperature in the tank need evidently rise less before pressure is transmitted through the connection tube to close the supply valve, and if adjusted upward the temperature must rise higher before closing will take place.

A relief element is also supplied which will yield if the pressure after the control valve has been closed should for some special reason continue to rise and exceed even the high limit of strength of the tubing. The element is a special heavy spring interposed between the manually adjustable head of the rod in the oil cylinder and the piston which the rod pushes. The spring strength is such that it will yield when pressure is too high, restoring itself to normal length when normal conditions are resumed.

An Automatic Starter for Induction Motors

In a paper recently presented at Chicago before the Association of Iron & Steel Electrical Engineers, H. F. STRATTON, vice-president and chief engineer of The Electric Controller & Manufacturing Company, Cleveland, Ohio, described an automatic starter for squirrel cage alternating-current motors. He said the need of an alternating current automatic motor starter has been clearly shown by the constant demand for something which would do for the squirrel cage motor, what the automatic starter has done for the direct current motor.

Unfortunately, the same advance has not been made in the development of the automatic starter for alternating current motors, although there are more squirrel cage motors in use than any other type of electric motor from the standpoint of numbers and total horsepower.

Speaking generally, the E. C. & M. automatic compensator starts a squirrel cage motor in the usual way, in that the motor initially receives a reduced voltage through a transformer, and after the attainment of considerable speed, the reduced voltage is withdrawn and line voltage is quickly applied to the motor. Beyond this similarity, the compensator differs radically from any existing equipment.

Fig. 1 shows the starter with cover removed. The case is full of oil and the machine itself is built in one unit and fits simply in the case.

Fig. 2 is a three-quarterd side elevation, showing the compensator in the "starting" position and Fig. 3 shows it in the off position. T_1 and T_2 are the two coils of an open-delta transformer. The voltage taps from this transformer are brought up to a terminal board which is above the oil level. Any one transformer is built up entirely of laminations of the same shape and size, so designed that they can be assembled with all joints lapped. The assembled transformer laminations are clamped between the transformer end frames, marked EF_1 and EF_2.

M is a U-shaped member built up of high-silicon steel laminations which are electrically welded together along six different places on the exterior of the magnetic circuit. Steel plates are also electrically welded to this frame, and are tapped so that, by means of bolts, the magnet may be attached to the main frame of the compensator. Three small horizontal slots and one larger horizontal slot are cut into the upper pole face. The three small horizontal slots are oil canals to permit the armature to open rapidly when the magnet is de-energized. In the large slot is held a copper bar, each end of which is riveted to a brass casting extending upward and supported by a slanting piece of molded asbestos board marked AB. This asbestos board also supports on its under side a cast grid resistance unit. The induced current flows through the copper bar, the two brass castings and the resistance unit when the magnet is in operation, and as this electrical circuit encloses only a portion of the upper pole, there are set up magnetic forces in different sections of the upper pole of the magnet which are out of phase with each other, and which prevent the magnet from chattering.

FIG. 1—COMPENSATOR WITH TOP OF CASE REMOVED

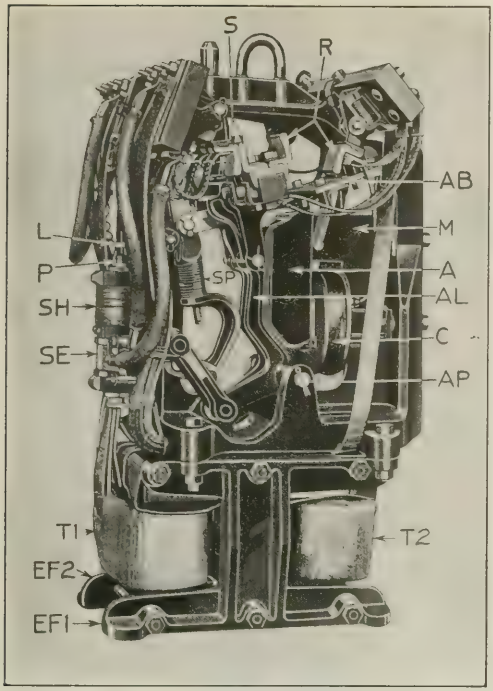

FIG. 2—COMPENSATOR IN STARTING POSITION

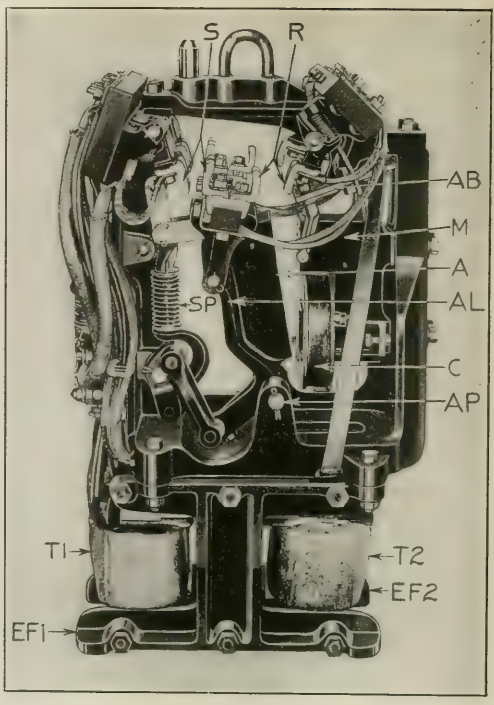

FIG. 3—COMPENSATOR IN OFF POSITION

The operating coil *C* encloses the lower pole of the magnet, and the wire is wound on a brass spool with supporting lugs.

At the face of the lower pole a strip of non-magnetic metal is loosely supported, forming a gap in the magnetic circuit when the armature is closed. This material is not only non-magnetic, but it also has high ohmic resistance, to reduce the heating and the useless wattage which would be caused by eddy currents which are set up.

The armature, *A*, is also built up of electrically welded steel laminations, and it is welded to the cast steel armature lever, *AL*, which is pivoted to the frame by means of the phosphor bronze rod, *AP*.

It will be noticed that there is only one operating magnet for the entire mechanism, and that this one magnet, when energized, must establish the starting connections and, after a delay, allow the starting connections to be broken and the running connections to be established. This is accomplished by an interesting mechanical movement. With the armature in its closed position, as shown in Fig. 2 it will be noticed that the contacts, *S*, are in engagement, establishing the starting connections to the motor, and that the spring, *SP*, has been compressed. The compensator remains in this starting position until it is released by the action of the transition relay. Its plunger, *P*, lifts when the starting current in the motor drops to a value which is suitable for a change in motor connections from the transformer to the line. When the transition relay operates, it raises the pivoted latch lever, *L*. This movement of the latch lever permits the compressions spring, *SP*, to act on a toggle joint, quickly throwing the movable contacts from the starting side to the running side; in other words, the motor is disconnected from the transformer and is connected to the line. When it is desired to stop the motor, with the compensator in either the starting or running position, the operating magnet is de-energized and all parts fall into the "off" position, shown in Fig. 3.

The following is a brief summary of the sequence of operations:

First, the operating magnet is excited, closing the armature, compressing a spring and connecting the motor to the source of supply through the transformer; second, after the motor has attained a suitable speed, the transition relay operates a latch, permitting the compression spring to disconnect the motor from the transformer and the transformer from the line and to connect the motor to the line; third, when the operating magnet is de-energized, the armature falls open and the motor is disconnected from the supply lines.

The transition relay shown in Fig. 2 includes a top shunt coil, *SH*, tending to lift the plunger, *P*, when energized, and a bottom coil, *SE*, in series with the motor in starting, tending to hold the plunger down when energized.

The transition relay is self-adjusting, in that the selection of the voltage taps also selects the right adjustment for the operation of the transition relay. In other words, the higher the votlage tap selected, the higher will be the value of motor-starting current at which the relay functions.

Personal

Mr. **James J. Bajda,** formerly chief dye chemist and chemical engineer for B. Heller & Co., has associated himself with the Block Chemical Laboratories, where he will have charge of their many dye plants now under construction.

Mr. **R. A. Bull,** formerly of the Chicago Steel Foundry, is now vice-president and general manager of the Duquesne Steel Foundry Co. His headquarters are in the Arrott Building, Pittsburgh, Pa.

Prof. **William Campbell** of Columbia University, New York, is now serving as consulting metallographist at the New York navy yard.

Mr. **J. D. Collier,** director of L. J. Healing & Co., Ltd., Tokyo, engineers and contractors, is visiting America on a short business trip and expects to arrive in New York the first week in August. His address is c/o W. J. Sparks, Inc., 17 Battery Place, New York.

Prof. **C. E. Davis** has resigned as professor of chemistry at the Utah Agricultural College at Logan, and accepted a position as research chemist for the National Biscuit Co., with headquarters in the Havemeyer Laboratory, Columbia University.

Mr. **H. M. Deavitt,** consulting chemist, with offices and laboratories in the Rookery, Chicago, Ill., has been elected a director of the Mechanics and Traders' State bank.

Mr. **George B. Hogaboom,** formerly plater with the International Silver Co., Meriden, Conn., has joined the research forces of the Scovill Manufacturing Co., Waterbury, Conn.

Messrs. **Henry D. Lindsley** and **Thomas C. Desmond** announce the organization of their business as investment bankers and engineers under the name of Lindsley, Desmond & Co., Inc., 31 Nassau Street, New York City.

Mr. **R. M. Klein** has been appointed sales manager of the International Oxygen Co., with headquarters at the company's main office, 115 Broadway, New York. Mr. Klein was formerly an engineer in U. S. Government employ, salesman and sales manager for the Diehl Manufacturing Co. and manufacturers' representative handling a number of mechanical lines. He entered upon his new association on July 1.

Mr. **A. W. Phillips,** for the past year general superintendent of the Aetna Chemical Co.'s Canadian smokeless powder plant at Drummondville, P. Q., has resigned this position to accept immediately the superintendency of the Canadian Electro-Products Co.'s synthetic acetone plant at Shawinigan Falls, Quebec. R. A. Lockerby, who has been the operating superintendent at Drummondville, succeeds Mr. Phillips in the position. Mr. Phillips formerly was superintendent of the Aetna Explosive Co.'s guncotton plant at Gary, Ind.

Mr. **Forest Rutherford,** for many years superintendent of Reduction Works for the Copper Queen Consolidated Mining Co. at Douglas, Ariz., severed his connections with the company on June 1 and will go into business for himself as a consulting metallurgical engineer. His present address is c/o First National Bank, Pueblo, Col.

Obituary

Prof. **K. Birkeland** of Christiania, the eminent Norwegian engineer who developed, in conjunction with Dr. Sam Eyde, the well-known Birkeland-Eyde nitrogen fixation process, passed away in Tokyo on June 18.

Professor Birkeland, who was born in December, 1867, was educated at the University of Christiania, and subsequently studied in Paris, Geneva and Bonn. In 1898 he became professor of physics at the University of Christiania, but prior to this he contributed a number of interesting papers on electric waves, on cathode rays and on atmospheric electricity to "Wiedemann's Annalen," the "Comptes Rendus," etc. On three occasions he got together and led expeditions for studying the polar aurora and magnetic disturbances, and the results of these expeditions have been published in Christiania and London. During some experiments in 1903 he discovered a special electric high-tension "disk flame." From this as a starting point, he and Dr. S. Eyde worked out a practical method for the production of nitrates from the air and as a result great manufactories for developing this process have been erected in Norway.

The results of this work were completely described in our Volumes II, III and IV, including a paper read before the Faraday Society by Professor Birkeland in 1906.

The Société Norvégienne de l'Azote et de Forces Hydro-Electriques are the owners of the Birkeland-Eyde patents, and at the beginning of 1908 the great Notodden-Svalgfos works were opened with 40,000 hp. Subsequently the company constructed works at Lienfos (15,000 hp.) and Wamma (55,000 hp.). With the Badische Anilin and Soda Fabrik, and two other German companies which possess their own method (the Schonherr), the Norwegian Nitrate Company has formed subsidiary companies which possess plants at Rjukan (227,000 hp.), Tyin (81,000 hp.) and Matre (83,000 hp.). Professor Birkeland was an honorary member of several learned societies.

CURRENT MARKET REPORTS

The Iron and Steel Market

The pig iron, unfinished steel and finished steel markets have come to a dead stop. In finished steel the buying had been of diminishing volume since April, the forward deliveries being more and more neglected while the early deliveries were largely unobtainable. The pig iron market had seen its greatest activity and its last price advances in June. Then, after the iron and steel price-control feature had been dropped from the food bill in the Senate, President Wilson published his statement urging mine owners and manufacturers to "forego unusual profits" and enunciating the "one price for all" doctrine, *i.e.*, for the Government, its Allies, and the general public. Business, already of small proportions, then ceased altogether.

That was a very easy thing for the market to do in a period of heavy demand. When times are dull no one buys ahead and if operations are at only one-half capacity it is necessary for business to be done almost every day. When everyone has bought far ahead, consumers are covered and producers' order books are filled, it is not necessary for new business to be done.

It was a combination of influences that brought the market to a stop. In the first place, prices had gone altogether too high all along the line. In the second place, there were no longer any prices for finished steel products for regular forward delivery. The Steel Corporation subsidiaries practically withdrew from the market in April, and afterward the quoted prices advanced, but they were really prices for early deliveries, what would be called premium prices if there were regular forward prices with which to compare them. In the third place, jobbers and manufacturing consumers became doubtful what their requirements really would be six months or more hence, with the country at war, labor scarce, and conditions generally changed. In the fourth place, Government fixing of prices was more or less expected either in the near or more distant future. Finally, President Wilson enunciated the "one price for all" doctrine, and that was the last thing needed to cause buyers to decide to stop and await developments.

Even if there were no influence whatever from Washington, the course of the market would be one of no activity for a period of months, except for occasional oddlot buying, until a new price level should be established. On such an occasion in the past prices have dropped to a point not far from the cost of production, buying being then resumed and being stimulated by the price advances that would follow. In present circumstances the case is different. The mills are not sold as far ahead as they usually become on such a protracted price advance as that of the past two years and a half, partly because they have been reserved in their sales policy and partly because buyers have also been reserved during the past few months.

There are various influences from Washington, however. The Government is to make large purchases of steel for itself and its allies. How large these purchases will be no one ventures now to predict, but the estimates of 30 days or more ago, that they may run to 40 or 50 per cent of the productive capacity, now seem to be rather high. It is no longer to be considered a foregone conclusion that they will take up the slack that is to be produced by a lighter scale of buying by the general public. The Bridge Builders' and Structural Society, for instance, reported that the fabricated steel bookings in June represented only 47½ per cent of a month's fabricating capacity, against 56½ per cent for May, also a small amount. The railroads have ceased buying entirely.

Another influence from Washington is the fixing of prices on steel for the Government. These prices are expected to be made within a few weeks, orders placed meanwhile being subject to the price to be set later. Last March, when special prices for the Government were under discussion, there were many steel manufacturers who objected on the ground that to give the Government a special price would mean that the whole market would work down to that level. Now, when it is settled that the Government is to have a special price, they doubtless prefer to express another view, but President Wilson has thrown the weight of his influence in the direction of one price for all. If the buyers also adopt his view they may be as successful in getting the market down as they have hitherto been in working it up, for it was chiefly competition among buyers, when mills professed an indisposition to sell far ahead, that produced most of the advance in the market.

The only prices that can be quoted for the market are prices for delivery in the next few months, which very few mills can compass, the following figures giving a rough idea: Bars, 4.50c. to 5c.; structural shapes, 4.50c. to 6c.; plates, 9.50 to 10c.; blue annealed and black sheets, 9c.; galvanized sheets, 11c. to 12c.; steel pipe, 42 per cent off list; nails, $4 per keg.

PIG IRON

The pig iron markets have come to a complete halt. Unlike the finished steel market, pig iron was being sold for regular forward deliveries, at prices substantially the same as those ruling on small lots for early shipment. On the prices ruling since late in June a little iron has been sold for the remainder of this year, with a considerable tonnage for the first half of 1918. The furnaces are sold up practically full for the remainder of this year, and to the extent of perhaps 40 or 50 per cent of their output for the first half of next year. In the second half of July there has been scarcely any business done. The fact that furnaces have not reduced asking prices is no evidence that they do not expect lower prices. It is never productive of business to cut prices after such an advance. Prices at all northern furnaces are a trifle above $50, at furnace, while Alabama iron is a shade under $50.

Non-Ferrous Metal Market

Wednesday, July 25.—There was very little activity in any of the metal markets during the past two weeks owing to the fear of Government regulation of prices. Labor troubles in the West are still holding up production. Copper is considerably lower and lead is lower in the outside market. Tin is virtually unchanged and spelter fractionally lower.

Copper.—The copper market has been very dull and little business has been done. Lake has dropped from 28.50 to 25.50 and electrolytic has dropped from 29.00 to 26-26.50. Some business has probably been done at slightly lower figures than this.

Tin.—About the only thing of importance in the tin market has been the scarcity of spot Straits, the price of which is now 62.50, or about ½ cent higher than on July 16. Tin is coming in regularly without loss. Chinese and Banca tin are slightly lower.

Lead.—The feature of the lead market has been the selling by independents at prices ranging down to 10.00 cents. The demand has been very poor. Labor troubles are still holding up production in the West, and on July 23 a slightly firmer tone reigned on this account.

Spelter.—The price of prompt spelter has remained virtually unchanged with fractional variations up and down. It is now about 8.60 New York. The market has been very dull.

Palladium	oz.,	110.00

Chemical Market

Coal Tar Products.—The past fortnight has witnessed a generally slow and easier market for practically all items under this classification and the usual

quietness incident to midsummer has prevailed. Stocks have accumulated in most cases and consumers have, as is usual in a weak market, shown little if any desire to buy.

Benzol.—Reports from practically all factors indicate rather ample supplies of benzol for nearby deliveries and with the basic material for the majority of coal tar products showing a tendency to weakness the general line of subsidiary products reflected this condition. Sales during the two weeks have been strictly confined to actual wants of buyers who are not inclined to purchase ahead in view of the easy tendency prevailing. On contracts there is a tendency on part of firms controlling supplies to hold off and business of this character has been unimportant.

Toluol.—The conditions governing benzol have found reflection in the market for next higher fraction to a minor degree however. Spot supplies have accumulated somewhat but important quantities of toluol are not generally reported in dealers' hands for immediate shipment. Spot values have receded somewhat and minor contracts covering deliveries for the next two months have been put through at very attractive figures. Contracts, however, are difficult to secure. Most firms in control of supplies are well sold. Several inquiries are in the market for large quantities but in view of the uncertainty as to the desires of the government these have not been closed.

Phenol.—A weak market continues and there does not appear to be any immediate hopes of relief for the manufacturer. A large production continues and this bears prices. Consuming demand from domestic sources is meagre and the only important transaction noted lately was for a large shipment to the Orient which was placed at the lowest figure so far prevailing this year.

Benzoic Acid.—The production continues at such an unusual extent that prices have sagged to the lowest level that has prevailed since the beginning of the war. Offers have been made under the $4 mark but it is rumored that manufacturers in their own interest will curtail the output which seems to be in excess of the consumption. The same conditions prevail in the market for *Benzoate of Soda.*

H Acid.—The entry of several new producers into the manufacture of this product has not so far resulted in lower prices. A firm of substantial standing is offering the product at 4½ cents per unit, material generally testing 82 per cent. This price, however, brings the cost of direct colors to a level that will allow of but limited competition with the large, old established firms producing their own H acid.

Gamma Acid.—There has been a production in a liquid form of this material in the Middle West for the consumption of the producer. It is now stated that a dry salt will shortly be marketed by this firm and in addition at least one other producer will shortly be in position to deliver.

Paramidophenol.—A larger production of this material is noted and while the older manufacturers are holding to previous quotations the new operators are cutting prices. The same conditions seem to prevail with *paraphenylenediamne.*

Salicylic Acid.—In contrast to other coal tar products the demand for this product has probably exceeded the supply one hundred to one. Production is centered in few hands but active and rapid preparation is being made to increaes the output and the market will probably go through the same process of elimination noted last year. This condition prevails in *salicylate of sodium* and *salol.*

HEAVY CHEMICALS.—The weakness in the market for *bleaching powder* seems to be the outstanding item of interest during the two weeks. Prices have sagged and sagged until the bottom more than dropped out. The product is a difficult one to move in the summer but no one expected a price that closely approximated pre-war times. *Caustic soda,* however, after a temporary weakness of one or two days strengthened and prices are again higher. This product continues to be the item of most interest to the chemical speculator. *Soda ash* has revealed firmness especially in futures. Spot supplies have been meagre and the demand has been rather urgent. *Copper sulphate* has moved slowly with a tendency to improve as we write. Prices are quietly firm. *Cyanides* are easier and not in special demand. Imports from England are somewhat heavier than usual. *Chlorates* have remained neglected. Domestic business is obtainable on a basis equal to that for export, so anxious are holders for business. *Epsom salts* are somewhat easier and supplies are more easily secured. *Formaldehyde* after a long period of firmness has eased off but supplies are not by any means large. *Phosphorus compounds* have continued scarce and high but a few cases have generally been obtainable from time to time. *Sodium nitrite* has remained practically out of the market and sales have passed above the 50c. level. This compares with a normal price of about 6c. Several productions are planned and contracts are being offered. *Nitrate of Soda* has sold at a record price and importers continue to express bullish views. *Sulphate of ammonia* has been practically eliminated from the market aside from contract business. An offer of 100 tons is very unusual. Prices have soared to unheard-of levels.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, JULY 23, 1917

Acetic anhydride	lb.	1.70 —	1.90
Acetone, drums	lb.	.32 —	.33

INDUSTRIAL

Financial, Construction and Manufacturers' News

Financial

New Companies

Aniline Bases Co., 1 Newark Street, Hoboken, N. J., $120,000. Manufacturing dyes, chemicals, etc.

Arkansas City Refining Company, Wilmington, Del., $500,000. Incorporators: Harry Emmons, Kenneth L. Emmons, Anna L. Dorsey, of Wilmington

Bookertee Smelting & Refining Co., Henryetta, Okla., $1,000,000. Incorporators: F. R. Bouldin, S. Walker and V. V. Grant, of Bouldin.

The C. P. N. Chemical Company, New York, N. Y., has been incorporated with a capital of $10,000, to manufacture chemicals. H. M. Peyser, G. D. Aranow and A. N. Harris, 320 Broadway, are the incorporators.

The Charleston Alloy Steel Company, Belle, W. Va., has been incorporated with a capital of $500,000, to operate a local plant. J. M. Payne, Berkeley Minor, Jr., and G. P. Brennan, all of Charleston, are the incorporators.

The Chemical Apparatus Manufacturing Company, Wilmington, Del., has been incorporated with a capital of $150,000 to manufacture chemicals. C. L. Rimlinger, and Henry M. Robinson, Wilmington; and Clement M. Egner, Elkton, Md., are the incorporators.

Chicago—Miami Lead & Zinc Co., Miami, $150,000. Incorporators: Wallace E. Shirra, Claude K. Church, Chicago; Charles McCafferty, Oklahoma City.

Corona Salt Co., Inc., Groton, N. Y., $425,000. Oil, gas and salt production. Incorporators: F. R. Miller, 120 East Eighty-ninth Street, New York City; E. A. King, 1215 Union Avenue, Bronx; S. M. Bell, Montclair, N. J.

The Dittenhoefer Tube & Rubber Company, New York, has been incorporated in Delaware with capital of $1,000,000, to manufacture automobile tires and tubing. Arthur W. Britton, Samuel B. Howard and John A Moore, all of New York City, are the incorporators.

The Durham Paper & Pulp Company, Phillipsburg, N. J., has been incorporated with a capital of $125,000, to operate a local plant. Walter L. Cochran, O. S. McConnell and E. Hulings Antrin are the incorporators.

East Chicago Foundry Company, East Chicago, Ind., $30,000, foundry. Directors: Harry C. Stuart, Henry S. Evans, Phili S. Graver, William F. Graver.

The Franklin Paint Co., Cleveland, Ohio, $10,000. F. H. Meier and others, incorporators.

The Great Western Potash Company, San Diego, Cal., has been incorporated in Delaware with a capital of $1,000,000, to manufacture potash and aluminum. J. A. and E. M. Henry, and W. E. Shaw, all of San Diego, are the incorporators.

Havemeyer-Seamans Oil Company, $10,000,000, acquire oil and gas lands and develop the same, construct railroads, etc. Incorporators: C. L. Rimlinger, Henry M. Robinson, Clement M. Egner, Wilmington, Del.

Independent American Oil & Sulphur Corporation, Wilmington, Del., $15,000,000. Incorporators: A. M. Holleran, M. H. Morris, Ferris Giles of Wilmington.

Kentucky Oil Company, Ashland, $200,000. Incorporators, Marshall Bond, Henry F. Benn, Frank M. Laird and C. C. McCoc.

Joseph G. Kessler & Co., Inc., Brooklyn, N. Y., $45,000. Smelting and refining zinc ore and its products. Incorporators: J. G. Kessler, B. Goldberg, 105 Kent Street, Brooklyn.

The Keystone Chemical Supply Company, Philadelphia, Pa., has been incorporated with a capital of $50,000 to manufacture chemicals. G. A. Street is the principal incorporator.

Lambert-Georgian Chemicals Corporation, Manhattan; capital $100,000. Drugs and chemicals. Frances Kriegel, Maurice Hotchner and Luis F. Cores.

The Lee Paper Box Company, Philadelphia, Pa., has been incorporated with a capital of $15,000 to operate a local plant. Edwin A. Lee is the principal incorporator.

W. C. McBride, Inc., Wilmington, Del., $100,000. Petroleum and natural gas. Incorporators: C. L. Rimlinger, Henry M. Robinson, Clement M. Egner.

The Massillon Steel Castings Co., Massillon, Ohio, has been incorporated for $250,000. The new steel plant will begin operation in a short time.

Montezuma Mining & Reduction Corp., $1,000,000, do a general mining business in all its branches. Incorporators: M. L. Rogers, H. W. Davis, L. A. Irwin, Wilmington, Del.

Nica Refining Co., Washington, D. C., $100,000. Incorporators: A. H. Coombs, H. P. Olden, of Washington.

The Oklahoma Consolidated Producing & Refining Co., Wilmington, Del., $5,000,000. The business of drilling and marketing oil, natural gas, etc.

Ossining Chemical Works, Inc., Ossining, N. Y., $25,000. Alkalies, drugs, and chemicals. Incorporators: A. F. McCabe, H. W. Bense, H. S. Ferrigro, 37 Wall Street.

The Ouachita Cotton Oil Company, of Camden, Ark., $60,000 ($37,000 subscribed). Incorporators: W. H. Warnock, T. S. Grayson, D. P. Baker, W. W. Boyd, A. A. Reid, J. O. Hutcheson, James G. Brown, J. L. Davis and C. W. McKay.

The Penn Paper Products Company, Philadelphia, Pa., has been incorporated with a capital of $50,000 to manufacture paper goods. LeRoy Jacobs, Philadelphia; Cyrus E. Tomlinson, McKinley, Pa., and George L. Townsend, Jr., Wilmington, Del., are the incorporators.

The Potash Extraction Corporation, New York, N. Y., has been incorporated with a capital of $100,000, to operate crushing plants and quarries for felspathic rock. G. F. McKay, D. Lillis and A. A. Alexander, 2 Rector Street, are the incorporators.

Priest-Lee-Bell Oil Corporation, Wilmington, Del., $300,000. To refine, market and develop crude oil and its products.

The Radiant Glass Company of Fort Smith, Ark., $10,000, filed articles of incorporation. Incorporators: George D. Carney, M. N. Carney and J. S. Parks.

The Sotter Brass Foundry Company, Pittsburgh, Pa., has filed articles of incorporation with a capital of $10,000, to operate a local plant. Charles J. Sotter is the principal incorporator.

The Southern Ferro Alloys Company, Chattanooga, Tenn., has been incorporated with a capital of $200,000, to operate a plant for the production of ferrosilicon, ferrochrome and kindred alloys. It is said that the company has acquired a site for the proposed plant and will commence operations with three electric furnaces. P. J. Kreusi is president of the company.

The Stalnaker Steel Company, Pittsburgh, Pa., has been incorporated with a capital of $150,000 to operate a local plant. Harvey D. Stalnaker is the principal incorporator.

Standard Asphalt and Refining Company, $5,000,000, to refine and market oil and products thereof. Incorporators: L. E. Phillips, J. B. Bailey, Dover, Del.

The Standard Tungsten Company, Newark, N. J., has been incorporated with a capital of $100,000, to manufacture tungsten specialties. R. T. Rodger and G. Dazet are the principal incorporators. C. H. Vail, 810 Broad Street, is agent for the company.

The Superior Glass Manufacturing Company, Martins Ferry, Ohio, has been incorporated in West Virginia, with capital of $50,000, to operate a local plant. Frank A. McMahon and R. R. Marshall, Wheeling, and William W. Davis, Cumberland, Md., are the incorporators.

The Sweetser & Bainbridge Metal Alloy Company, Albany, N. Y., has been incorporated with a capital of $10,000 to manufacture metal alloys and metallic compounds. S. P. Sweetser, E. F. Bainbridge and H. G. Batcheller, Albany, are the incorporators.

The Tennessee Paper Mills Company has been incorporated with a capital of $200,000 to manufacture paper boxes. The new factory will make two kinds of paper, straw board and chip board.

Transportation Petroleum Company, New York, $1,000,000: F. Fried, G. M. Healy, New York; Liciam Ross, San Antonio, Tex.

The United States Nitrates & Ammunition Company, New York, N. Y., has been incorporated in Delaware with a capital of $100,000 to manufacture nitrates of soda products and other specialties. William L. Underwood, Patchogue, L. I.; George E. Wilson, New York; and Elmer E. Fowler, Spencer, N. Y., are the incorporators.

Virginia Chlorine Products Co., Newark, N. J., $1,500,000, chemicals. Incorporators: Henry Van Arsdale, Jr., Newark; C. J. Kulberg, New York.

The White Chemical Company, Louisville, Ky., has been incorporated with a nominal capital of $5,000 to manufacture chemicals. I. L. and Emile Steinfeld and W. G. Rork are the incorporators.

Capital Increases

The Erie Iron & Steel Company, Erie, Pa., has increased its capital from $100,000 to $500,000.

The Hewitt Rubber Company, 240 Kensington Street, Buffalo, N. Y., has increased its capital from $1,000,000 to $1,500,000. The company specializes in the manufacture of air brake hose for locomotive service.

The Buffalo Pressed Steel Company, Buffalo, N. Y., has recently increased its capital from $30,000 to $75,000.

The Minotola Glass Company, Minotola, N. J., has increased its capital from $100,000 to $500,000 for expansion.

Construction and Operation

California

INDIAN FALLS.—The Noble Electric Steel Company, which is already engaged in producing electrically smelted steel in commercial quantities at its plant in Heroult, Shasta County, has taken a lease upon the manganese mining property originally located by Messrs. Mason and Braito, situated at the "watering trough" near Indian Falls.

J. Carey is superintending the development work which is now being started. It is reported that the company intends to build a 700-foot tramway and to prosecute the work with a crew of 30 or 40 men. The manganese property is situated almost on the line of the Indian Valley Railroad.

MARTINEZ.—The Shell Oil Refinery will expend $1,000,000 on its plant. A contract has been let for nine 55,000-barrel steel tanks.

REDDING (Shasta County).—At a special meeting of the directors of Noble Steel Electric Company, operating at Heroult on the Pitt River, W. H. French, vice-president and general manager of the Judson Manufacturing Company, has been elected vice-president and general manager. H. H. Noble, the man who developed the plant at Heroult, retains his stock in the company, but it is understood he has given his proxy to French.

The new general manager has been head of the Judson company for five years and during that time increased the business from one-quarter to three millions a year. Already he has made arrangements with the United States Government to take the ferromanganese, ferrochrome and ferrosilicon being turned out at Heroult.

H. E. Bothin, president of the Judson Manufacturing Company, is backing French in his venture at Heroult.

Dr. W. W. Clark will remain in charge of all plant operations.

The plant now has two furnaces working 24 hours a day; one on ferromanganese, turning out 8 to 10 tons every 24 hours, and the other on ferrosilicon, turning out 5 tons every 24 hours. The company also has ready three small furnaces, each of which will turn out one and a half tons of ferrochrome every 24 hours.

Slow shipments of electrodes from the East and freight tieups have held down production at Heroult, but the railroads have assured the new management that since they are making ferroalloys all materials will be rushed.

SAN BERNARDINO.—Building of a sodium reduction plant in San Bernardino

will begin within a few days. Sodium deposits on the desert will furnish the material.

SAN FRANCISCO.—A $350,000 refining plant for cocoanut oil is contemplated in San Francisco. Mr. C. E. Johnson of Milwaukee, president of the Johnson Manufacturing Company, is looking for sites.

SAN FRANCISCO. — The Fleischhaker Paper Co. has taken a lease on a 4-story 123 x 130 ft. reinforced concrete factory to be built at Second and Harrison Streets by the Clinton Construction Co., Twenty-first and Treat Streets. It was purchased for $125,000.

SAN FRANCISCO.—Plans have been completed for the 1-story mill and foundry building to be erected for the Jewell Steel & Malleable Company at Potrero Avenue and Twenty-fifth Street. The building will cover an area of 148 by 108 feet. Further extensions will be erected as soon as this unit has been completed.

SAN FRANCISCO.—Potash is said to be the secret of the recent declaration of a 13 per cent stock dividend to the shareholders of the Santa Cruz Portland Cement Company, on stock of record July 14. A large stockholder of the company said yesterday tha the Santa Cruz is no wmaking 600 pounds of potash daily, with only a single unit of an inexpensive plant in place and in operation. This potash is a by-product, extracted from the flue dust and fumes generated in making the cement. It is figured that with eight kilns in operation the company ought to make two tons of potash daily.

Delaware

WILMINGTON.—The Harlan & Hollingsworth Corporation, West Street, has filed plans for the erection of a new copper and tin shop at its shipbuilding plant.

WILMINGTON.—The Wilmington Steel Company, it is said, is planning for the rebuilding of its 18-inch mill and other sections of the plant recently destroyed by fire with loss of about $150,000. The Midvale Steel Company, Philadelphia, operates this organization.

Florida

JACKSONVILLE.—General Manager J. C. O'Dell of the Municipal Docks and Terminals announced recently that he had concluded arrangements with F. M. Whittle, manager of the Florida division of the Virginia-Carolina Chemical Company, to have the branch plant of that company located on the properties of the Municipal Docks and Terminals near the St. Johns Mill Road. The space will be approximately three acres, and will have buildings on it to cost between $150,000 and $250,000. These buildings consist of warehouses and manufacturing plants and an acid tower.

Idaho

WALLACE.—The Tamarack & Custer Mining Company has resumed work on its properties in the Cœur d'Alenes after a lull of three months. The company, which owns a half interest in the smelter at Northport, Wash., according to a report, will send its ore to the Bunker Hill & Sullivan smelter at Kellogg. This move is taken on account o fthe difficulty in getting coke at Northport.

Illinois

CHICAGO.—The Marks Manufacturing Company will expend $14,500,000 in the construction of its new steel works at East Chicago, which is $9,500,000 in excess of the estimated cost a year ago. A 600-ton blast furnace, complete with docks, ore and coke handling machinery, an open-hearth steel department with a capacity of 250,000 gross tons of ingot a year, and a universal plate mill with a capacity of 180,000 gross tons of universal and sheared plates will be added.

Iowa

DES MOINES.—A deal was closed to-day for the purchase of an acre of land at East Twenty-sixth Street and Dean Avenue by the Keith Furnace Company of 336 Southwest Eleventh Street. It is planned to erect a four-story factory and a large one-story foundry, which will be a modern, fireproof, daylight type building. R. S. Keith is owner of the plant.

Kentucky

HELLIER.—The Allegheny Coke Company is reported to be planning for the installation of a new battery of coke ovens to double the present output, making a total capacity of about 20,000 tons of coke per month.

Louisiana

NEW ORLEANS.—Steel rolling mill promoters have enlisted the services of a broker to seek a large site on a public belt railroad and served by water transportation. The promoters have incorporated under the law of Delaware as the Dixie Steel Corporation, with a capital of $500,000 to utilize high-grade scrap iron.

Maryland

BALTIMORE.—The Crown Cork & Seal Company, Guilford Avenue, will build a new four-story, reinforced-concrete plant at Foster Avenue and Twelfth Street. The structure will be 30 x 125 ft. and will be equipped for the manufacture of bottle stoppers and kindred specialties.

Minnesota

DULUTH.—The Minnesota Steel Corporation will expend two million dollars for construction work. The enlargement of the plant will begin at once, and includes two blast furnaces and four open-hearth furnaces, costing $1,500,000, plans for which are already under way. Erection of a benzol plant was started some time ago, costing $500,000, and is expected to be in operation in eight months. A second unit of furnaces will be constructed next year, consisting of six blast furnaces and fourteen open hearth furnaces.

MINNEAPOLIS.—A one-story factory building 100 by 120 ft. is being built at Johnson and Broadway, which will be occupied Sept. 1 by the Columbia Chemical Company to manufacture phosphoric acid, caustic soda and fertilizers.

MINNEAPOLIS.—Coincident with the opening today of the Mississippi River navigation to Minneapolis the Columbia Chemical Company announced it will build a plant here and bring Tennessee phosphate rock by river transportation for treatment. The plant will comprise for the present a brick and steel two-story building on ground 100 by 150 feet and a boiler house 40 by 50 feet. The Austin Company of Cleveland has the contract. C. N. Lockwood is secretary of the new company and George Walker, chemist, is the technical head. The plant will make sodium phosphate, caustic soda, phosphoric acid and sodium sulphate.

Montana

BUTTE.—The selection of a site for a rod and wire mill at the plant of the Boston-Montana Smelter of the Anaconda Company at Great Falls, Mont., is officially announced. The mill will involve an expenditure of $700,000 and will have a daily capacity, with only one shift working, of 200,000 pounds of copper rods and 65,000 pounds of copper wire.

GREAT FALLS.—Owing to the strike in Butte, the Washoe smelter of the Anaconda Copper Mining Co. has closed, and the Great Falls smelter has curtailed production. Plant here is out of copper concentrates, and copper refinery is also short. Labor troubles in Butte is reflected by the decrease from 20,000,000 to 8,000,000 pounds of copper for the June output.

HELENA.—Representatives of Pennsylvania steel mills are now in Granite County looking over the ground with a view to erecting a large smelter for the reduction of manganese ore.

HELENA.—Employees of the East Helena smelter of the American Smelting & Refining Company were notified recently of a voluntary increase in pay of 25c. per day, to prevail as long as the sale price of lead is $11 a hundred weight or more.

KELLOGG.—The Bunker Hill & Sullivan Mining & Concentrating Company's big smelter is almost ready for complete operation. Roasters are taking ore, and the furnaces will be blown in within 10 days. The first of the cintering machines has been adjusted and the other four machines will be put in operation. Ore for the first blast will be supplied by the Bunker Hill & Sullivan mine, which made the erection of the smelter possible. The Hecla Mining Company at Burke, Idaho, will become one of the large contributors.

Nebraska

OMAHA.—The United Oil & Refining Company has commenced operations on its 25,000-acre lease in Madill Field, Bryan County. Mr. C. J. Bowman, formerly vice-president of the Southern Oil & Gas Company of Tulsa, is president.

New Jersey

JERSEY CITY.—The American Can Company, 120 Broadway, New York, is reported to be negotiating with the local Chamber of Commerce for a site in the Fairmount Terminal section for the construction of a new plant, to cost about $500,000.

JERSEY CITY.—The Interstate Chemical Company will build a one-story addition to its plant on Garfield Avenue, near Marcus Street.

JERSEY CITY.—The Natural Products & Refining Company, manufacturer of refined oils, etc., will build a new one-story plant at Jane and Commercial Streets.

NEW HOPE.—The Union Paper Bag Company is building an addition to its plant.

NEWARK.—The Balbach Smelting & Refining Company, Avenue R and Doremus Avenue, has filed plans for the construction of two one-story additions to its plant, 49 x 100 ft. and 29 x 90 ft., respectively.

NEWARK.—The Nicklesburg Brothers' Company will build a one-story shop addition, 34 x 40 ft., to its leather manufacturing plant on Meadow Street.

NEWARK.—The Hanson & Van Winkle Company, 269 Oliver Street, manufacturer of chemicals, etc., will build a new two-story plant, 46 x 50 ft., on Adams Street, to cost about $15,000.

PARLIN.—The T. A. Gillespie Company has acquired about 640 acres of property in the vicinity of its powder plants at Parlin and Runyon, and is reported to be planning for the construction of extensive additions to provide for increased capacity.

PATERSON.—The East Jersey Pipe Corporation, East Thirty-sixth Street, is remodeling and improving its works to provide for the manufacture of shells. New machinery is being installed. It is planned to commence operations early in August.

PERTH AMBOY.—The General Bakelite Company, manufacturer of insulation specialties, has commenced the erection of a five-story addition to its plant, about 50 x 80 ft., to be used for increased capacity. The company is a subsidiary of the Roessler & Hasslacher Chemical Company, Fayette Street, Perth Amboy.

ROCKAWAY.—The New York & New Jersey Chemical Company has been organized to take over the former plant of the Lincoln Architectural Iron Company, and equip and operate the works for the manufacture of chemicals.

New York

BUFFALO.—The plant of the Buffalo Copper & Brass Rolling Mill Company, 446 Military Road, has recently been acquired by the American Brass Company. The works, which have been used for the manufacture of rolled copper and brass, will be operated at full capacity.

BUFFALO.—The Sizer Forge Company, 238 Larkin Street, manufacturer of steel forgings, is planning to lease property over the Mill Race Strip for extensions to its plant.

FARMINGDALE, L. I.—The Farmingdale Chemical Company has purchased the former plant of the E. C. Nelson Manufacturing Company, to be used for the manufacture of chemicals.

LONG ISLAND CITY.—The Oakes Manufacturing Company, foot of Blackwell Street, manufacturer of dyewood specialties, will build two reinforced-concrete additions to its plant, to consist of a three-story building, 30 x 100 ft., and a two-story structure, 60 x 80 ft.

POUGHKEEPSIE.—Negotiations were concluded recently looking toward the establishment of the Reliance Aniline Chemical Company of Brooklyn in the vacant factory of the Standard Concrete Construction Company.

SYRACUSE.—The Syracuse Malleable Iron Works, North Geddes Street, specializing in the manufacture of metal wheels for motor trucks, is planning to increase the plant capacity from 25 to 40 sets of wheels daily.

TOTTENVILLE, S. I.—The Tottenville Copper Company has filed plans for the erection of a two-story addition to its plant on Bethel Avenue.

WATERVLIET.—The Ludlum Steel & Spring Company, Fifth Street, manufacturer of crucible cast steel specialties, is planning for the erection of a two-story addition to its plant on Spring Street.

Ohio

CLEVELAND. — The Clarke - Kessler Chemical Works has purchased from a Cleveland syndicate 17 acres between the

New York Central tracks and St. Clair Avenue and east of Lloyd Road in Wickliffe for a consideration of about $25,500. The first unit of a chemical plant which will cost about $30,000 has been started.

COLUMBUS.—Work will start soon on the modern factory sheds which are to be built on Bonham Avenue at the plant of the General Chemical Co., to cost about $100,000.

PORTSMOUTH.—The William R. Pollock Co. will soon complete a blast furnace for the Whitaker-Glessner Co., after which resources of the concern will be devoted to building a furnace for the Tate Iron & Steel Co. of Sakchi, India.

Pennsylvania

BETHLEHEM.—The Bethlehem Steel Company has awarded a contract for the construction of a one-story, brick and steel addition, 60 x 120 ft., at its Sparrows Point, Md., plant, to be used as a copper shop. The Singer-Pentz Company, Baltimore, has the building contract.

COLUMBIA.—The Keeley Stove Company, Second and Maple Streets, is planning to increase its capital from $200,000 to $300,000 for extensions.

FAYETTE CITY.—The Pittsburgh Steel Products Company announced recently mammoth building projects, including new plants and a new town and involving an expenditure of more than $3,000,000. The extensions will be located in Allen Township, Washington County, on the Monongahela River. The land was purchased last fall and work has already begun.

LANSDALE.—Fire recently destroyed the plant of the Lansdale Rope Works, with loss of about $20,000. It is said that the plant will be rebuilt. The Barrows Manufacturing Company, Lansdale, operates this property.

MARIETTA.—The National Casting Company is making rapid progress in improving and extending the former plant of the Marietta Manufacturing Company, recently acquired, for the production of iron and steel castings. J. H. Foreman is head of the company.

PHILADELPHIA.—Barclay White & Co. and H. E. Baton are estimating on plans for alterations and additions to the plant of the Surpass Leather Company, at Ninth and Westmoreland Streets.

PHILADELPHIA.—Charles Lennig & Co., manufacturers of chemicals, are building a two-story addition to their plant on Richmond Street, to cost about $11,000.

PHILADELPHIA. — The Philadelphia Drying Machine Company, Westmoreland Avenue, has awarded contracts for the erection of a new plant at Westmoreland Avenue and Stockley Street, to cost $40,000. The new site will be used as the main plant of the company, which specializes in the manufacture of drying machinery, allowing for the removal from its present Germantown works.

PITTSBURGH.—The Cunningham Glass Works properties on the south side is under option to the Jones & Laughlin Steel Company for a price of about $200,000. The property consists of the old glass factory on a lot measuring 360 x 120 feet at Mary and South Twenty-sixth Streets, and two large vacant lots, measuring 252 x 120 feet and 264 x 120 feet on Jane and South Twenty-sixth Streets.

PITTSBURGH.—The Jones & Laughlin Steel Company, Third Street, is said to have acquired an option for the purchase of the plant of the Cunningham Glass Works, Mary Avenue, for about $200,000. It is said that the plant will be used for extensions.

READING.—The Reading Malleable Iron & Steel Company is reported to be planning for the erection of a new plant at Norristown.

Tennessee

CHATTANOOGA.—Actual manufacture of ferroalloys will probably begin in October at the old plant of the Southern Steel Works in Chattanooga, which has been taken over by the Southern Ferro-Alloy Co. Hydroelectric power will be obtained from the Tennessee Power Co., 3000 hp. having been contracted for. The first product of the new company will probably be ferrosilicon, 50 per cent or higher. The plant of the old steel company is fairly well adapted to the new purpose, but three months will be necessary for its remodeling and for the installation of machinery, which was designed by the FitzGerald Laboratories, of Niagara Falls, N. Y.

CHATTANOOGA.—The Tennessee Paper Company, recently organized with capital of $200,000, is planning for the construction of a local plant with capacity of about 50 tons daily. The mill is estimated to cost $150,000. A. M. Shepherd is head of the company.

Texas

HOUSTON.—The contract has just been awarded by Swift & Co. of Chicago for the construction of a cottonseed oil refinery here to cost $250,000. It is stated that a specialty will be made of converting cottonseed oil into a lard substitute and other cooking materials. The buildings will be of fireproof brick and concrete construction.

HOUSTON.—R. S. Sterling, president of the Humble Oil & Refining Company, which was chartered recently at Austin with a capital stock of $4,000,000, stated that they will build a refinery with a capacity of at least 3000 barrels of crude daily at Fort Worth, which will be started as soon as the material can be assembled.

Virginia

GOSHEN.—The Southeastern Iron Corporation, Tower Building, Chicago, recently organized with a capital of $500,000, is reported to be planning to take over the plans of the Goshen Iron Company and the Victoria Iron Company. It is proposed to remodel and improve the works to provide a total capacity of 200 tons daily. The extension is estimated to cost $150,000. Francis H. Hardy is president.

Washington

CHEWELAH.—Handy & Chippendale, who have leased the Double Eagle mining properties near this city, will erect three calcine kilns in the development of the magnesite property.

COLVILLE.—The Crown Willamette Paper Company of Portland, Ore., will develop its dolomite properties near here, the dolomite to replace magnesite in paper making. Field kilns for calcining the dolomite will be installed.

KELLER.—The Manila Copper Mining & Smelting Company, Keller, Wash., has been organized, and will operate a 200-ton smelter in Keller. A smelter at that point, built nine years ago, but never blown in, will form the basis of the plant. Plant has copper stack with 150 tons capacity; lead stack of 50 tons; electric power plant, sampling room and laboratory. Considerable new equipment will be added, and the plant put in operation to handle commercial ores.

NORTHPORT.—The Electric Point Mine has opened up a vein of solid high grade lead carbonates in a body 59 ft. wide. Property is to be developed on a large scale.

NORTHPORT.—The Northport Smelter here, at a cost of $100,000, is putting in a Cottrell plant for the saving of values in the smelter smoke. The smelter has been losing $600 a day through its smoke, and it is claimed this plant will pay for itself in six months.

NORTH YAKIMA.—The Utah Idaho Beet Sugar Company's plant at North Yakima is nearing completion. It will have a capacity of 500 tons of beets per 24-hour day and it is estimated to cost $400,000 to $500,000. A novel feature in the equipment being installed is a pulp dryer which, so far as the Utah Idaho company is concerned, is a new departure.

NORTH YAKIMA.—Harry Y. Saint, secretary of the Commercial Club, states that according to a telegram from Eastern interests, a potato starch factory will be erected in the near future in the city.

PORT ANGELES.—A plant will be established in this city by the Washington Pulp & Paper Company for the extraction of tannin from hemlock bark for use in the tanning industry. Plant will have capacity of 24 cords of bark daily.

SEATTLE.—The Charles A. Newhall Company, chemical and inspection engineers, Seattle, has received contract for inspection of a large order of creosoted timber and creosoted piling, work to be done under U. S. Engineer's Office, Major E. J. Dent. The Newhall Company is associated with the Pittsburgh Testing Laboratory.

SEATTLE.—The Hurley-Mason Company, Hoge Building, has received contract for construction of coal bunkers and 60 beehive coke ovens at Croker for the Carbon Hill Coal Company.

SEATTLE.—The Pacific Coast Steel Company, headed by William Piggott, has purchased the plant of the Oregon Steel & Iron Works at Oswego, Ore., and will put the plant in operation for the manufacture of pig iron, using ores from the west coast of South America. The plant cost $300,000 and was built twenty-five years ago. It has been idle a large part of the time. The Pacific Coast Steel Company also announces the merger of the Seattle Car & Foundry Company of Seattle with the railway car-building plant of Twohy Bros., of Portland and Spokane, under the name of the Pacific Car & Foundry Company. William Piggott is president of the new concern. The company recently purchased and is putting in operation the Irondale plant of the Western Steel Corporation, where blast fornaces are being installed. An extensive program of car building, pig iron manufacture and industrial development is planned by the new corporation.

SPOKANE.—The United Copper Mining Company, according to Conrad Wolfe, president, will immediately double the capacity of its concentrating plant. The plant will have increased capacity of 600 tons daily. New equipment to be installed will include tube mill, 10 tables and classifiers.

SPOKANE.—The American Fire Brick Company's branch plant will be established here at once. An old brick plant has been taken over by President-Manager C. F. Oudin, and will be converted into a plant for manufacture of calcined magnesite, magnesite brick and other magnesite products. All of the machinery in the plant will be scrapped, and new equipment, costing $25,000, will be installed.

SPOKANE.—The Giant Ledge Mining Company, operating large mining properties in the Coeur d'Alenes, plans the installation of a 150-ton mill, which will later be enlarged to twice that capacity.

West Virginia

BELLE.—A deal was closed recently by New York interests for the Slack Farm at Belle, a town 12 miles east of Charleston, on the Kanawha and Michigan side of the river, on which property they propose to construct a million dollar electrical refining plant to refine high-grade chemicals and by-products from other factories now located in the Kanawha district.

MOUNDSVILLE.—W. H. McSwain and associates have organized a company to operate a local plant for the manufacture of glass rolling machinery.

SISTERSVILLE.—The Independent Glass Company is making extensive repairs to its plant which will make it almost like a new plant when it is completed. New tanks and two new ovens are being placed in the plant and the stack has been raised 35 ft. and four new sections of roof have been put in place. Five gas producers will be installed and two 50-horsepower boilers will be added.

WHEELING.—The Wheeling Chemical Products Company, 3102 Jacob Street, has been manufacturing matches, glue and other chemical products since the first of the year and promises to be one of the large match factories of the world.

WHEELING.—The Wheeling Mold & Foundry Company, manufacturer of iron and steel castings, is planning for the operation of its plant at maximum capacity for the production of battleship armament. It is said that the works will be devoted to this specialty for the next twenty-four months.

WIERTON.—The Phillips Sheet & Tin Plate Company, specializing in the manufacture of cold rolled strip steel and tin plate, is planning for the construction of additions to its plant to increase the present output.

Alaska

CORDOVA.—About 200 mines in the Bonanza and Jumbo Mine, the property of the Kennecott Copper Corporation, have struck for wage increases of from 15 to 50 per cent, depending on market price of copper. About half of the crew is at work.

SEWARD.—The Seward Brick & Tile Company has leased a site in this city and will establish a brick and tile manufacturing plant. Large deposits of the finest pottery clay have been tested and found available.

SEWARD.—The big mill of the Alaska Juneau Mining Company, now operating four units, or about one-third of its maximum capacity, will have all twelve of its units in operation within thirty days About 100 men will be employed.

SEWARD.—William Martin, here, announces that on account of the high cost of cyanide he will not operate the cyanide plant this season, but has installed a centrifugal amalgamator which will remove the gold from the slimes.

British Columbia

FERNIE.—Coke has started to move from the Crow's Nest Pass collieries, and four furnaces of the Grand Forks smelter

of the Granby Consolidated & Mining Company will be blown in shortly. Production is 60 per cent normal, and in the near future 400 tons of coke will be turned out daily from the ovens at Fernie. The two-months strike has been terminated, and most of the men are back at work.

TRAIL.—About 40 tons daily is the average output of the electrolytic zinc smelter of the Consolidated Mining & Smelting Company. The first story of the No. 4 treater plant, requiring 150,000 brick, is practically finished, and steel is being erected.

TRAIL.—The Trail smelter of the Consolidated Mining & Smelter Company, according to a report recently issued, received 3852 tons of ore in the seven days ending June 14, as compared with 2749 tons in the last previous seven days. The mine which made the greatest number of tons shipment to the Trail smelter for the year is the Sullivan Mine at Kimberley, which is unaffected by the coal strike. Its total to date is 61,462 tons. The output is zinc ore, which is treated at the Consolidated company's electrolytic plant at Trail, and requires no coke for smelting.

VANCOUVER.—As a result of the Crow's Nest Pass coal strike, the metalliferous mining industry in the Kootenays is at a standstill, there being at present an extreme shortage of coke.

Manufacturers' Notes

JAPANESE INDUSTRIAL ACTIVITY IN MANCHURIA.—The Government General of Kwantung and the authorities of the Manchuria Railway Company are taking steps to develop industries in the railway zone, and especially in and about Dairen, according to Commerce Reports. They have been making investigations with special reference to the manufacture of oil from Manchurian beans and of soda from Kwantung salt, as well as the zinc-refining and iron-refining industries. The railway company already has acquired the right to exploit a Chinese iron mine, and it is expected that operations will be started before the end of the year. It is now reported that the authorities have nearly completed arrangements for undertaking the soda industry. What shape the project will assume is not yet definitely known, but according to one report, it will be undertaken by the Dai Nippon Engyo Kaisha, which has the sole right of importing Kwantung salt into Japan proper, with the financial assistance of the Manchuria Railway Company. Messrs. Suzuki & Co. and the Mitsui Bussan Kaisha, according to another report a separate joint stock company with $1,985,000 capital will be established for the purpose.

It is understood that the authorities are in communication with Suzuki & Co. and other capitalists interested, and that the project will soon materialize. It will have the advantage over similar undertakings in Japan proper of getting supplies of Kwantung salt at less than 7½ cents per 100 lb., as against 24½ cents paid at home. With this cheap supply of material, it is hoped that the new company will be able to compete with British and German rivals successfully, even after the conclusion of the war.

It is said that a project for the manufacture of bean oil also is maturing. Apart from these official or semi-official undertakings, there have been increased private undertakings for spinning and weaving recently in the zone of the South Manchuria Railway Company.

AMERICAN CHEMICAL COMPANY TO OPERATE IN BRAZIL.—The American Chemical Works (Inc.), with headquarters in Wilmington, Del., has been authorized by the President of Brazil to operate in the Republic, according to Commerce Reports. The capital of the company is said to be $50,000, and the amount set aside for operations in Brazil $10,000.

A. H. NEY, INC., consulting chemists and chemical engineers, have taken over from Moses, Pope & Messer, the chemical laboratories hitherto occupied by the latter at 76½ Pine Street, New York. Mr. J. M. F. Leaper, vice-president of the company, is in charge as director of the laboratory.

THE ASBESTOS PROTECTED METAL COMPANY of Pittsburgh announces the temporary closing of its Cincinnati office on August 1, 1917, due to the fact that Mr. E. G. Irwin, Cincinnati manager, has entered the Ohio national guard. Communications addressed to the home office, First National Bank Building, Pittsburgh, will receive immediate attention.

THE LACKLAND-PAYNE REFRACTORIES COMPANY, composed of Henry K. Lackland and James K. Payne, announced the opening of their office at 1603 Boatmen's Bank Building, St. Louis, Mo. The company is in a position to make prompt shipment of firebrick and clay.

AMERICAN CATALOGUES WANTED. —The American Chamber of Commerce for Italy, located at Via Victor Hugo No. 4, Milan, desires to secure catalogues and price lists from American firms relating to all kinds of goods. This organization, which was formed over two years ago, now has a membership of over 500 and is doing a great work in promoting trade relations between the United States. Recently it has established a trade catalogue library and desires to make it more complete. It is in possession of many catalogues, but desires to secure duplicates for this reason firms that have already sent one copy are requested to send another, and other firms are asked to forward them in duplicate. In addition to the catalogue library the chamber possesses a library containing books on trade information. It solicits contributions in this line also.

BROMINE AND CALCIUM CHLORIDE. —According to figures recently compiled by R. W. Stone, of the United States Geological Survey, the quantity of domestic bromine marketed in the United States in 1916 was 688,260 lb., valued at $922,225. This quantity includes only elemental bromine made from natural brines pumped in Michigan, Ohio, and West Virginia; it does not include bromides, the salts of bromine that are widely used in photography and medicine. The production reported in 1915 was 555,857 lb.

Bromine is used instead of chlorine as an oxidizer in many chemical reactions, and for dissolving gold and separating it from platinum and silver; it is also used in disinfectants, drugs, and photographic chemicals, and in making aniline colors. Recently it has been extensively used in making the asphyxiating gases employed in the European war.

The quantity of calcium chloride made from brine and sold in the United States in 1916 was 26,062 short tons, valued at $216,729, an increase of 22 per cent in quantity and 65.7 per cent in value over the production of 1915. This quantity does not include calcium chloride obtained in the manufacture of soda, as calcium chloride so obtained is not an original constituent of the brine.

Calcium chloride is made from natural brines at Mount Pleasant and Saginaw, Mich.; Pomeroy, Ohio, and Mason, Hartford and Malden, W. Va. As the same brines yield salt and bromine, practically every constituent of them is turned to profit. Calcium chloride is used as the circulating fluid in refrigerating plants, in cement concrete, and in automobile gas-engine radiators to prevent freezing, and for laying dust on roads, drying gases, vegetables, and fruits, and dehydrating organic liquids. Calcium chloride in solution is especially valuable in automatic-sprinkler systems and in fire buckets.

LARGE INCREASE IN SALT USED BY CHEMICAL WORKS.—The domestic consumption of salt in 1916 was 15,720,860 barrels of 280 lb. each, an increase of more than 3,000,000 barrels over the consumption of 1915. According to statistics compiled under the direction of R. W. Stone of the United States Geological Survey, the domestic production of salt in 1916 was 15,449,329 barrels, the imports were 871,992 barrels, and the exports 600,461 barrels. This was an increase of 19 per cent in the quantity of salt produced. The total value of the salt was $13,645,947.

Michigan, as usual, was the largest producer, and New York was a close second. The production, in barrels, by the leading States was as follows: Michigan, 14,918,278; New York, 14,087,750; Ohio, 4,706,193; Kansas, 4,564,793; California, 1,124,236.

Perhaps the most marked feature in the salt industry in 1916 was the great increase in quantity of brine sold as such or used by chemical works, the increase being 37 per cent and the total production over 18,000,000 barrels. The production of rock salt increased over 17 per cent and amounted to 9,973,950 barrels, valued at $2,685,270. On the other hand, the production of evaporated salt increased only 5 per cent, to 17,575,629 barrels, but the value was $10,149,412, an increase of nearly 15 per cent.

FELDSPAR PRODUCED IN 1916.—The production of feldspar in the United States in 1916, as reported to the United States Geological Survey, was 118,465 long tons, having a value as crude material, f.o.b. mines, of $404,689. Of this amount 75,165 long tons entered the market as crude feldspar, valued at $251,372, and 48,496 short tons were ground by the producers and sold for $450,906. During the year the price of crude spar averaged about $3 per long ton and of ground spar about $9.30. Feldspar was mined in the following States, named in order of quantity produced by each: North Carolina, Maine, Maryland, New York, Connecticut, Pennsylvania, Georgia, Virginia, California, New Hampshire, Vermont. The output came chiefly from 50 quarries, but a like number of small or intermittently worked deposits contributed materially to the total.

Feldspar is used mostly in the pottery and enameling industries, which consumed 82 per cent of the year's output. Probably less than 1, 2, and 3 per cent, respectively, of the total output were used for chicken grits, soap, and other abrasive purposes, and in making glass. Roofing and cement surfacing consumed about 7 per cent and an equal proportion was used in preparing fertilizers and in the experimental extraction of potash.

DISTRIBUTION OF ITALIAN SULPHUR SUPPLIES. — An announcement has been made, according to Commerce Reports, by the Minister of Munitions that in connection with the distribution of Sicilian sulphur the Italian Government has allotted certain specified quantities to each of the Allied Governments, and accordingly the British Government will purchase hereafter directly from the Italian Government the quantity allotted to Great Britain. The distribution in England thereupon will be undertaken by the Ministry of Munitions. A committee has been appointed to deal with the matter and it has decided to offer to supply imported sulphur in lots of not less than 5 tons for use in approved trades and industries. The prices per ton for the present will be: Flowers of sulphur, $112; roll brimstone, $102; thirds, $60.83, including delivery to the purchaser's nearest railway station.

From the prices mentioned above a discount of 2½ per cent will be allowed to recognized sulphur merchants and dealers, but not to consumers. Applicants claiming this discount must furnish satisfactory evidence that they were recognized sulphur merchants or dealers before the war.

The committee understands that "recovered" sulphur can be procured, in the ordinary way of business, from the home producers.

Manufacturers' Catalogs

FALKENBURG & LAUCKS, Seattle, Wash., has issued a booklet on "Ore Testing Schedules," dealing with different tests.

THE HOSKINS MANUFACTURING COMPANY, Detroit, Mich., has issued Bulletin 3-A, June, 1917, describing Hoskins pyrometers.

THE ECONOMY FURNACE APPLIANCE COMPANY, Chicago, Ill., has issued a pamphlet on "Stop Making Smoke."

THE LINK-BELT COMPANY, Chicago, Ill., has issued an interesting booklet on "The Ideal Drive for Textile Machinery."

THE GENERAL FILTRATION COMPANY, Inc., Rochester, N. Y., has issued a booklet on "Filtros," describing physical and chemical properties, shapes and sizes, grades, uses, electro-filtros, installations, containers and care of filtros.

SAUVEUR & BOYLSTON, Cambridge, Mass., has issued a pamphlet on "Photomicrographic Apparatus" describing and illustrating their different instruments.

THE CHICAGO PNEUMATIC TOOL COMPANY, Chicago, Ill., has issued Bulletin 34-Y on "Gas Gasoline Driven Air Compressor."

THORDARDSON ELECTRIC MANUFACTURING COMPANY has issued sheets on their transformers, wireless and low-voltage, jump spark coils and make and break coils.

D. R. SPERRY & CO., Batavia, Ill., has issued an attractive catalog on the Sperry Filter Press with illustrations.

Profits of the Steel Corporation

Earnings of the steel companies increased through the second quarter of this year and unless production is greatly curtailed by hot weather the earnings in the present quarter will make a new high record. In presenting its report for the second quarter, the United States Steel Corporation deducted an allowance for the excess profits tax on the basis of the House bill as reported to the Senate July 3. It is correct, of course, to deduct taxes before reporting earnings, but at the same time this particular tax is upon profits. The first quarter earnings had been reported without deduction, of course, but the estimated amount for the first quarter is deducted from the surplus previously reported for the quarter. To harmonize the reports for the two quarters the figures may be presented thus:

	First quarter.	Second quarter.
Total profits	$113,121,012	$144,498,076
Excess profits tax	33,863,000	53,918,872
Earnings remaining	$79,258,012	$90,579,204

The excess profits tax thus computed is not particularly onerous, even though it represented 30 per cent of the total profits in the first quarter and in the second quarter 37 per cent. The second quarter earnings, even with the tax deducted, were at the rate of $362,000,000 a year, whereas the earnings in 1916 were $333,574,178, and the earnings in the best preceding year, 1907, were $160,964,674.

Since the latter part of 1915 the tonnage output of the Steel Corporation has not varied greatly. There has been an increase on account of new plant capacity, but not as large an increase as occurred in the case of the independents. Last winter, output was materially restricted on account of traffic congestion on the railroads which persisted even to the second quarter of this year. The earnings were about $17,000,000 per month in the last quarter of 1915, and they amounted to about $50,000,000 last June, without allowance for the excess profits tax. By far the major part of the increase in earnings has been due to higher prices realized on the shipments. These increases followed advances in the open market by a period of from six to nine months, as the corporation has been sold well ahead. Last December, January and February the earnings were less than in the preceding November, this being due to restricted production, coupled with the fact that from May to July inclusive, the steel market had not advanced materially. Beginning with last March there have again been large increases continued in monthly earnings. The June shipments were chiefly against sales made last November, as an average period, and as the corporation's prices

continued to advance until the latter part of April further increases in earnings per ton are to be expected. The corporation did not participate in the advances made by independent mills in May and June.

The utterly fictitious character of the finished steel market as lately quoted is brought out by some simple comparisons. The June shipments were about 1,250,000 gross tons, while the total profits were $50,000,000. There is good ground for estimating that the average invoice price of the shipments was at least $60 a ton less than the lowest prices now quoted as "the market": 4½ cents for bars and shapes, 8 or 9 cents for sheets, 9 or 10 cents for plates, and so on. Were such prices realized the profits would be $100 per ton instead of $40 and a month's total profits would be $125,000,000, equal to $1,500,000,000 for a year. As the corporation, at present, is less than a 50 per cent interest, the steel industry's total profits would be considerably in excess of three billions a year, or about three billions greater than the average profits in the three years preceding the war. Serious question has been raised whether a much less amount than this could be raised in war taxes without greatly disturbing business. If there is question whether all the industries of the country together cannot pay two billions without having their activities impaired, it is quite certain that one class, the consumers of steel, could not possibly pay an extra three billion to the producers of steel.

No doubt the steel producers realize this fact perfectly. They have shown no disposition to point it out, and two reasons for the reticence may be assigned. First, they would like to see the business run along with consumers paying higher and higher prices until something breaks of its own accord. Second, they have been fearful of the Government exacting from them prices so low that nothing like a reasonable profit would remain. For this fear certain persons in position of more or less authority have given good ground, for repeatedly they have spoken of "cost plus 10 per cent" which is absurd in the case of steel, because in the case of an integrated concern, meaning 75 to 85 per cent of all the production, the capital is turned over, at full operation, once in from two and a half to three years, so that 10 per cent on the cost of production is from 3 to 4 per cent on the investment, with no allowance for depreciation and exhaustion allowances.

The Steel Corporation realized the danger of the situation when last April it ceased advancing its prices. Its last official prices average fully $30 a ton lower than the prices now quoted as the market, while its realized prices in June were as much below its quotations.

A readjustment in steel prices is about to occur, whereby a level will be reached at which business can be conducted, and it will readily be observed that very great reductions from the present fictitious quotations can occur without pushing earnings of steel producers below an extremely satisfactory level. In the meantime, buying by private consumers and the allied governments has been almost entirely held up, awaiting some stability in prices before making future commitments.

The Handwriting on the Wall

Commodity prices are up, away up beyond that warranted by the present wage scale; either the wages must go up, or the prices come down to a more equitable ratio—a disastrous explosion of domestic disorders will unquestionably follow a maintenance of the present status. It may be accepted without argument that prices, taken by and large, are too high. Even thoughtful manufacturers have been moved to restrain if possible the unconscionable antics of the soaring markets by urging caution, knowing the truth in the old song, "Never birdie flew so high she didn't have to light." And in that "lighting" is the rub—for prices have been so top heavy that a readjustment is absolutely necessary, and yet the danger of a crash is imminent. One of the most pressing problems before the American government, manufacturer and common citizen, is therefore the ways and means of getting the prices of raw materials and finished products down to reasonable levels, and that safely.

Individual effort on the part of isolated manufacturers of unusual public spirit will not affect the desired result, for his patriotic differential would be meat for the middleman, as long as other producers demanded and could get a higher price for the same material.

On the other hand, a representation from the producers meeting and agreeing upon a "fair and equitable" price would be little more successful. On the face of it, this seems to savor much of illegal combinations for fixing prices, and is very liable to all the ills of monopolistic control. A glowing example of the way this scheme would work is before our eyes from the conference of bituminous coal operators. Here a standard price of three dollars a ton at the mouth of the mine was promulgated, a price promptly denounced as exorbitant by a cabinet member, and frankly acknowledged by the coal trade to be so good as to allow them a very fattening income to make up for "lean" years in the past. Even though the scheme would work better with other more patriotic and more centralized industries, such as aluminium, the difficulties grow apace with decentralized, poorly organized producers, such as, for instance, fertilizers.

If only the Government were concerned, if it were the only buyer of a certain commodity, an "excess-profits tax" would in effect lower prices to a reasonable figure. England, for instance, through her Ministry of Munitions, controls essential industries, both as to their labor conditions and their profits, the latter being generally limited to 120 per cent of the average before the war, any excess going to the government. Should the Government be the only consumer it would be entirely indifferent what price might be charged, since all excess returns as taxes. What boots it, however, to ruin less fortunate corporations and individuals through extortionate prices for necessities, in order that a larger excess-profits tax might go into the national treasury? Even though the outsider survive, the arrangement savors much of hateful taxation without representation; furthermore the principle of "one price to all" is lost.

A further suggestion advanced by paternalists is that the Government bodily take over and operate certain basic industries. This scheme is too un-American to receive much consideration. Or rather, the American public is so familiar with the uneconomical and graft-ridden administration of certain public undertakings, that they have a suspicion that such hastily devised governmental operation would be quite likely to defeat its own ends. American industry is so delicately interrelated and depends so much upon the directing force of innumerable keen masters to run along of its own inertia after the operating minds are removed and replaced by well-meaning but less competent bureaucrats.

If one were willing to accept the hackneyed excuse of the profiteer—the overworked "law of supply and demand"—he might think that the best way to reduce prices was to reduce the demand, that is, to curtail consumption. If the entire consuming public could be reached and convinced and induced to reduce its consumption, the demand for a certain commodity, or for all commodities, for that matter, might be reduced to such a point that one cause for high prices would be eliminated. To state this possibility is but to realize its impossibility. Yet in some such manner must and will the prices of munitions to the Government be reduced. And if we mistake not, the tools are already in the hands of the Government, and the Government is proceeding to use them. It now behooves the industries to read the auguries, and direct their steps accordingly.

The twins "supply and demand" are hybrid; the terms are not of the same order. The expressions "supply and requirement" and "offering and demand" are of the same order. The former is material, the latter is mental. "Demand" is what people ask for, "offering" too often is the bluff of the producer; "supplies" are really the material on hand to sell, and "requirements" represent the real needs of the consumers. Prices can evidently be raised by a large demand and small offering as readily, or even more readily, than by a long requirement and a short supply; the danger one can not see is the worst feared. In fact the producer is now busy explaining that present prices are really fictitious in that they cover a low volume of sales forced to that level by the demand of excited consumers whose immediate requirements had not been contracted for months ago.

Yet if prices can be boosted by a commercial poker game, they certainly can be lowered by like mental processes. Witness the stagnation of business and the abrupt halt in price ascension immediately following the President's statement about "Patriotism and Profits," and his proclamation of adherence to the "One Price to All" principle. The requirements still exist; yet the demand has vanished.

Now comes the War Industries Board and their Central Purchasing Commission with advisory power over all army and navy contracts. These committees are composed of men who know their business, who have been in touch with big business long enough to be informed of the total production of any one commodity, to remember the prices which a year or two ago were returning a very fair profit to the manufacturers, and to understand the effect which altered conditions and wage advances should have upon these prices. They also have at their disposal correct information as to the exact figures the allied governments are paying for their munitions, both at home in "controlled" industries, and abroad on contracts. With this combined experience, knowledge and data, the War Industries Board will call into conference with it committees of producers of munitions—steel, alcohol, gasoline, motor trucks, copper, what you will—and say to this committee of manufacturers, "We want fifty per cent of your output of ship plates, we will pay 2½ cents a pound on account, and hold the exact price in abeyance pending investigation of the actual costs by the Federal Trade Commission."

Then the American manufacturer can do two things. He can either accept the offer of the business, gracefully and patriotically, or he can refuse. But on second thought, can he refuse, short of shutting down his plant? For suppose he elects to refuse the Government business and attempts to renew business on the present basis of maybe 6, hopefully 10 cents per pound. Who else but the Government is buying ship plates just now, what with the activities of the Shipping Board in laying down new construction and commandeering ships on the ways? And would England wish to buy ship plates from America at maybe 6, hopefully 10 cents a pound, when she can get them at home for 2½ cents? Or where would the steel man get bottoms to ship his metal even though he find a neutral market? After surmounting these difficulties, who would lift the embargo on plates from his suffering shoulders? Or does he delude himself into thinking the independent structural steel fabricators or tank and boiler makers are coming to his rescue for any higher price than the "one price to all" assured by the President?

The consumer views the situation with equanimity. The psychological aspect is pregnant with power: the demand is sentimentally lacking; the material aspect is overbearing in its weight: the requirements are artificially limited. The price is bound to come down, and the manufacturer should steer his course accordingly, and at once, thankful that he is assured of a just price, "a price which will sustain the industries concerned in a high state of efficiency, provide a living for those who conduct them, enable them to pay good wages, and make possible expansion of their enterprises which will from time to time become necessary as the stupendous undertakings of this great war develop." Where could he find extenuating circumstances to justify more liberal treatment from consumers, at last with the whip hand?

Of course the war industries board has advisory capacity over Government purchases only. But private enterprise can wait for a price adjustment—absolutely nothing *must* be done to-day excepting that which is necessary for the war. Then too, the illustration is taken from a certain branch of the steel industry because its control has been best accomplished at the present day. For ship plates merely substitute TNT, tungsten, pyrite, or what not.

The Sulphuric Acid Treatment of Gasoline

To the Editor of Metallurgical & Chemical Engineering

In these critical times when practically the whole world is one vast battle ground, every conserving influence for the preservation of food, steel, ships, or petroleum, is of importance.

In a warning given at Washington on May 25, 1917, Mr. Van H. Manning, director of the Bureau of Mines, stated that:

> One of the serious problems confronting the United States at this time is the production and consumption of petroleum and gasoline in the United States. The situation is serious, and it is my purpose to give you a few of the essential facts and allow you to draw your own conclusions as to the remedies that ought to be applied. As a nation, we are wasteful, apathetic and forgetful. We waste our natural resources with shameful prodigality, we are apathetic of the future.

On July 22, 1917, Mr. A. C. Bedford, president of the Standard Oil Company of New Jersey, and chairman of the committee on petroleum of the Advisory Commission of the Council of National Defense, stated:

> If our government is to have the petroleum it will need to prosecute the war successfully, and supply all necessities directly growing out of the war, two steps will have to be taken, namely:
>
> 1. The public will have to economize in the use of gasoline. Sufficient gasoline should be available to provide for the normal uses of automobiles. But pleasure riding should be curtailed. People should look upon their automobiles as necessities to be used only when needed. Not a gallon of gasoline should be used in the present emergency except for some useful end.
>
> 2. Every oil producer in the country should be encouraged as a patriotic effort to secure the utmost possible output of crude oil.

It is the purpose of this note to indicate that 700,000 barrels (in round numbers, 30,000,000 gal. of gasoline) could be saved in the refinery by eliminating the sulphuric acid, caustic soda, and washing treatment—in short, by marketing the gasoline direct from the steam stills.

The Federal Trade Commission's "Report on the Price of Gasoline in 1915," contains the following data:

Year	All Gasoline Engines, Total Horsepower	Per Cent Increase	Gallons Gasoline Sold by All Refiners	Per Cent Increase
1913	11,279,143		1,099,350,000	
1914	13,887,331	23	1,331,230,000	21.09
1915	22,524,858	62	1,849,790,000	38.95

The above table clearly indicates the greater increase in the percentage of gasoline-engine horsepower in comparison to the percentage increase in gasoline production. From 1913 to 1915 the total horsepower doubled and it is reasonable to believe that from 1915 to 1917, the increase will be quite as much. Since this increase seems to be assured, it is absolutely vital to this country that every gallon of gasoline be conserved, not alone on the ground of sound economics, but for the larger issues involved in this war. For the motor car and motor truck on the various battle fronts are the very arteries linking supplies and hospitals with the fighting men.

It has been estimated that in the year 1917, 70,000,000 barrels, or 3,000,000,000 gal. of gasoline will be marketed by the various refiners. In the refining of one barrel of gasoline average practice would show the use of at least 1 lb. of 66-Be sulphuric acid, with 0.1 lb. of caustic soda, and approximately ¾ of a barrel of water for washing. This entails a loss of *at least* 1 *per cent* of gasoline due to treatment with sulphuric acid, caustic soda, and washing. Of course, it is recognized that if benzine is treated with acid (which is the practice in a number of plants) that there may be a slight variant from the above figures, but even then the loss would be well within the above figure of 1 per cent.

Tabulating the above values in terms of actual gallons and tons of material involved on the estimated amount of 70,000,000 barrels, or 3,000,000,000 gal. of gasoline to be marketed in 1917, there would result:

Loss of gasoline due to sulphuric acid treatment	700,000 bbl.	30,000,000 gal.
Tons of sulphuric acid used to treat 70,000,000 bbl. of gasoline	35,000 tons	
Tons of caustic soda used to treat 70,000,000 bbl. of gasoline	3,500 tons	
Water used in treating 70,000,000 bbl. of gasoline	52,500,000 bbl.	2,205,000,000 gal.

The above table excludes the costs of equipment and of handling the large quantities of material involved. The total cost of acid treatment adds considerably to the cost of gasoline per gallon, which is naturally shouldered by the consumer, giving him a highly questionable return in "better product" for the difference in cost.

The acid treatment of gasoline adds very little, *if anything*, to the value of the resulting product. The acid treatment removes unsaturated hydrocarbons from the gasoline, which hydrocarbons have a greater driving power in a motor than saturated or paraffine hydrocarbons. Moreover, the specification of a water-white gasoline as one of the tests of its fitness is much overrating its value to the gasoline.

There are no valid objections to the use of a gasoline with a tinge of color or so-called odor in it. Take as an example a cracked gasoline with a tinge of yellow in it. Refining with sulphuric acid to rid the gasoline of the tinge of yellow or slight odor does not add anything to the gasoline as a motor fuel. In short what valid objections are there to the use of a gasoline with a slight odor or a tinge of yellow or red as in the case of some cracked California gasolines?

In view of the above data as to the conservation of 30,000,000 gal. of gasoline, it seems advisable to the writer, not alone to conserve the gasoline but also the sulphuric acid, caustic soda, water treatment, equipment, and man power used in the unnecessary refining of gasoline as conducted to-day. The minimum saving in economic wealth would be $10,000,000.

Gustav Egloff.

Methyl Alcohol and Acetone as By-Products of the Soda Pulp Industry

To the Editor of Metallurgical & Chemical Engineering

SIR:—With reference to our communication produced on page 416 of your edition of April 15, 1917, we note that we have in error transposed the quantities of methyl alcohol, and acetone, higher ketones and aldehydes, respectively. The "Spirit Test," second line on page 417, first column, should read as follows:

Spirit test: 30 per cent methyl alcohol, and 70 per cent acetone, ketones and aldehydes.

BLAIR, CAMPBELL & MCLEAN, LTD.

GLASGOW, SCOTLAND.

An Independent Company

To the Editor of Metallurgical & Chemical Engineering

SIR:—Permit me to correct an erroneous statement which appeared on page 150 of your number of Aug. 1, 1917, concerning the General Bakelite Company of which I am president. The General Bakelite Company, contrary to your statement is not a subsidiary of the Roessler & Hasslacher Chemical Company nor of any other company.

L. H. BAEKELAND.

GENERAL BAKELITE CO., NEW YORK CITY.

Soldiers, Attention!

Keep Us Informed of Your Enrollment

A regular supply of reading matter will go a long way in relieving many dull and tedious hours necessarily endured by the men and officers of the National Army, cut off from home ties and usual occupations. Each technical man in service will bless the existence of his magazines on their arrival, hailing them even as an old and tried friend. To that end the subscribers of METALLURGICAL AND CHEMICAL ENGINEERING are urged to keep the subscription department constantly and correctly informed by postal card of his company, regiment and corps, in which case every effort possible will be made at this end to see that he receives his paper promptly.

Coming Meetings and Events

American Chemical Society, Boston, Sept. 10-15.

National Safety Council, New York, Sept. 10-15, 1917.

National Exposition of Safety and Sanitation, New York, Sept. 10-15, 1917.

Third National Exposition of Chemical Industries, Grand Central Palace, New York, Sept. 24-29, 1917.

American Institute of Metals and Foundrymen's Association, Boston, week of Sept. 25 to 28, 1917.

Technical Association of the Pulp and Paper Industry.—Joint meeting with the Technical Section of the Canadian Pulp and Paper Association, Holyoke, Mass., Sept. 27 to 29, 1917.

American Electrochemical Society, autumn meeting, Pittsburgh, Oct. 3-6, 1917.

American Institute of Mining Engineers, annual meeting, St. Louis, Oct. 8-13, 1917.

American Gas Institute, Washington, D. C., Oct. 16-19, 1917.

American Society of Mechanical Engineers, New York, Dec. 26-29, 1917.

Western Metallurgical Field

Labor Troubles Curtail Copper Production

The output of copper of the United States has been seriously curtailed as a result of a long train of labor troubles in the Rocky Mountain region. During the last month strikes of greater or less extent have multiplied in various mining camps from Alaska to Arizona;—in some places the difficulty of wages was no sooner adjusted than another strike against camp living conditions was declared. Kennecott, Butte, Globe-Miami, Clifton-Morenci, and Bisbee all have been practically shut down. In most of these places the Industrial Workers of the World,—or more properly known from their initials, the "I Won't Work"—were very active in fomenting the strikes, often openly avowing a purpose of handicapping the Government by crippling the copper producing industry. The situation was further aggravated by feuds between the I. W. W. and the International Union of Mine, Mill and Smelter Workers, headed by Charles H. Moyer, until it was impossible to find out just what the trouble was about, and what body of men should be approached with negotiations. The impossibility of any patriotic appeal to these men is evident from the fact that nearly half of the employees of the copper mines in some States are aliens, working here only to "make a stake."

Under such circumstances the demands made by many strikers were merely "hold-ups," and it is only a question of a short time when an ignorant, unskilled laborer now dissatisfied with $5 a day and striking for $6, will be striking for $7 if he is given the present demand. In nearly all instances the present pay is based upon a sliding scale depending upon the price of copper, and consequently is now two-thirds greater than it was before the war.

In nearly all cases a settlement of the troubles has been made or is well under way, leading to an increase of wages of some amount up to about 50 cents a day. In the meantime exciting events, bloodshed, murder and treason have occurred. At Bisbee, after a double killing, a citizens' committee aided by deputy sheriffs loaded over a thousand I. W. W. members and sympathizers, both residents and floaters, into freight cars and escorted the train over the border into New Mexico, where the exported men were taken into custody by the Federal troops. At Butte a new scale at about 25 cents a day increase was adopted by the operators, and a reformation in the obnoxious "rustling-card" system instituted. Squabbles between various metal-worker unions prevent any general settlement, although the Federal mediator, W. H. Rodgers, has been able to conclude terms with most of the belligerents. The small hold of the I. W. W. on that community is evident from the comparative quiet following the lynching of one of their most violent agitators. In the meantime, however, hundreds of experienced miners have left the district rather than become involved in the trouble, and the scarcity of labor has thus been greatly accentuated.

The Leadville Strike

Unlike most of the strikes in the West, the Leadville strike was not an outcome of I. W. W. activities. It was simply a universal demand of the strikers for a raise in pay, based on the idea that with the present prices of metals the operators are making a greater

profit, and no attempt was being made on the part of the operators to raise the wages of the miners to balance the increased cost of living.

The minimum wages paid prior to the strike was $3.50 per day. Several of the mines operating in the district used a sliding scale for wages based on the value of the individual, but still holding the minimum rate as stated above. In this manner daily wages as high as $5.50 were paid to some of the laborers.

Within the past two years the wage scale of the district has been raised 16 2/3 per cent, that is, the minimum was raised from $3 per day to $3.50. The present demand of the miners was for an increase of $1 over the $3.50 per day. To this the mine operators objected, claiming that the profit made per ton of ore on such a basis would be so low that it would not pay to operate in the district. Leadville is a low-grade silver, lead, zinc camp and with the increase in cost of materials essential for mining operations, it would then be practically impossible to work the district profitably.

The situation was investigated by the State Industrial Relations Commission of Colorado, whose final findings were that the miners were not justified in their demands. It was found by the commission that the rents had not been increased for the past ten years. Food, clothing, shoes and other materials essential for the up-keep of the families of the miners had increased in the same proportion as the same goods had increased in Denver. Board had increased $5 per month due to the increased cost of food. On the other hand, the operators were found not to receive anything like the full benefit of the increase in metal prices, due to the existence of old contracts and unequitable smelter schedules.

The mine operators then offered an increase of 50 cents per day to the minimum wages paid. This the miners refused to accept and all mediation on part of the governor and the commission seemed of no avail, but after a three-days session between the mine operators and the representatives of the labor faction it was decided that operations at Leadville be resumed on Aug. 2 based on the 50 cents per day increase.

The settlement of the trouble was made more difficult by the refusal of the mine-operators to treat with delegates of the union, feeling that it would only be an entering wedge for the same element whose domination terminated in a bloody struggle several years ago. The present union has enrolled far less than half of the miners of the district, and a bare majority of their membership voted the strike. This faction is generally thought to be the Austrian element in the union, and the strike was quite unpopular among the American miners.

Midyear Spelter Report.—The United States Geological Survey, from returns representing 99 per cent of the output, estimates that the production of spelter during the first six months of 1917 was 364,000 short tons, as compared with 351,000 short tons during the last half of 1916. Stocks on hand are estimated at 33,000 tons as compared with 17,600 at the beginning of the year. A large number of retorts, about 35,000, including fourteen complete plants, were reported idle June 30, in addition to the retorts engaged in refining prime western metal and in redistilling zinc ashes.

Fuel Oil Situation Growing Serious in West

A report has just been completed by the committee recently appointed by Governor Stephens of California to make an investigation of the petroleum resources of that state, with particular regard to the industrial and military needs of state and nation in the present war emergency. The substance of the report was published in the *Engineering News-Record* Aug. 9, 1917.

The committee found that the oil production in California (whence comes one-third the entire supply of the United States and about one-quarter of the world's supply) is falling behind consumption at the rate of 35,860 bbl. per day. This excess of consumption over production is now being taken from oil in storage, and at the present rate the storage in California will be reduced to the 10,000,000-bbl. safety margin by Sept. 20, 1918. Should consumption increase or production decrease, both of which are likely unless immediate action is taken, the safety margin will be reached at an earlier date.

The seriousness of the situation is emphasized by the fact that considerable time is required to adapt power equipment for other sources of energy. It is pointed out in the report that fuel oil is largely used in the operation of the steam railroads of the Western States, the Panama Canal, steamship lines, cement plants, mines and smelters, gas plants, sugar refineries and, in general, a substantial portion of the manufacturing, industrial and agricultural enterprises of the Western States.

CONSUMPTION EXCEEDS PRODUCTION

The oil production in California has not been increasing in recent years. In 1914 it was 103,620,000 bbl.; in 1915 it was 89,570,000 bbl.; and in 1916 it was 91,820,000 bbl. The production in 1917, indicated by the present conditions, would be about the same as last year. The report points out, moreover, that further substantial increases in the annual petroleum production cannot be expected through the discovery of new fields or large extensions of existing fields.

Throughout 1916 the consumption exceeded the production by an average of 1,100,000 bbl. per month, or 36,650 bbl. per day. During the first five months of 1917, consumption exceeded production by 5,415,000 bbl., or 35,860 bbl. per day. Of course, the storage has been reduced correspondingly. Although the total remaining storage on July 1, 1917, is reported to have been about 38,000,000 bbl., this would be reduced to a much lower figure if limited to available fuel oil, because a considerable percentage is light oil, is below tank outlets or is otherwise unavailable. The stored oil is owned principally by the Standard and Union oil companies.

The substitution of coal for fuel oil was considered in the investigation, and the conversion of steam railroads from oil to coal burners in regions adjacent to coal fields is touched upon in the report. However, apart from the changes already made or contemplated, there is little possibility of further conversion from oil to coal during the war, unless the conditions surrounding the production and transportation of coal materially change.

The substitution of hydroelectric energy has already taken place to a considerable extent in industrial and

agricultural uses, but this has been hampered by difficulty in securing copper and other material and also by the disturbance of existing conditions that would be entailed by diverting large blocks of hydroelectric energy to service previously rendered by oil-burning plants. Large additional oil saving through the substitution of hydroelectric energy cannot be expected during the war, the report states; but after the war and the restoration of normal industrial conditions, wherever hydroelectric energy is available it will play an increasingly important part as a substitute for the fuel. Meantime, interconnecting the transmission systems of electric companies is suggested as a means of eliminating or at least reducing the necessity of maintaining steam-electric plants.

RELIEF MEASURES

The difficulties standing in the way of prompt and substantial increase of production must be quickly removed, the report states, if a serious industrial crisis is to be forestalled. The emergency cannot be met without the assistance of the Federal Government, and the report urged that California state officials make direct appeal to the administration at Washington.

While it is believed possible to increase production more than 30,000 bbl. per day, this increase cannot reasonably be expected to be available before June 1, 1918. To secure the best and most immediate results the committee recommends:

1. That production be increased immediately, by additional drilling on the lands which can be developed in the least time with the smallest expenditure of material and labor.

2. That every effort be made to reduce field losses, to encourage the highest use of petroleum and its products and the substitution of other forms of fuel or power where possible.

3. That the Federal Government be promptly advised of the situation and asked to render every assistance possible.

4. That manufacturers of oil-well supplies and the railroads be directed to expedite the production and transportation of oil-well casing, drill stems, wire cables and similar material—bringing the influence of the Federal Government to bear, if necessary.

5. That all skilled workmen in the oil fields be exempted from military service.

6. That lands in litigation be developed either through the Federal receivers or through the claimants to the lands, with due regard to the rights of all parties. (In this connection it is notable that 70 per cent of the desirable undrilled lands are involved in litigation with the Federal Government.)

7. That additional lands be thrown open for development by the Federal Government.

8. That steps be taken immediately to correlate the transportation facilities of the railroad, steamship, oil-pipe and oil companies, that transportation may be expedited, and

9. That as far as possible the burning of unrefined petroleum be prohibited.

The committee, which is officially known as the Committee on Petroleum of the State Council of Defense, consists of Max Thelen, president of the California Railroad Commission; Eliot Blackwelder, professor of geology, University of Illinois; and David M. Folsom, professor of mining engineering, Leland Stanford, Jr., University. The preliminary outline of the committee's report was telegraphed to Washington on July 7 by Governor Stephens, and a prompt acknowledgment was received by wire signed by President Wilson, expressing appreciation of the importance of the work and promising Federal support for the general plan.

Boston Meeting of American Institute of Metals

The following tentative program of papers has been prepared for presentation at the meeting of the American Institute of Metals to be held in Boston, Sept. 25 to 28, 1917:

Crucibles and Furnaces:

"The Crucible Situation," by Prof. A. V. Bleininger, Bureau of Standards, Pittsburgh, Pa.
"Melting Yellow Brass in New Form of Induction Furnace," by G. H. Clamer, Ajax Metal Co., Philadelphia, Pa.
"The Crucible Situation," by M. McNaughton, Jos. Dixon Crucible Co., Jersey City, N. J.
"The Electric Furnace & Non-Ferrous Metals," by Dwight D. Miller, The Society for Electrical Development, New York City.
"My Experience with Metal Melting Furnaces," by W. H. Parry, National Meter Co., Brooklyn, N. Y.

Melting and Casting Non-Ferrous Metals:

"Casting Bearings in Sand & Metal Molds," by R. R. Clarke, Pittsburgh, Pa.
"The School End of the Job in Training Foundrymen," by C. B. Connelley, Dean, Carnegie Institute of Technology, Pittsburgh, Pa.
"The Flux & Cleaner Question of Brass," by E. A. Frohman, S. Obermayer Co., Pittsburgh, Pa.
"Negative Experiments on Waste Core Sand," by Dr. H. W. Gillett, Bureau of Mines, Ithaca, N. Y.
"Pyrometers—Their Construction & Application," by John P. Goheen, Brown Instrument Co., Philadelphia, Pa.
"Surface Tension & Deoxidizing of Metals," by W. J. Knox, Metals Deoxidizing & Refining Co., New York City.
"The Briquetting of Non-Ferrous Light Metal Scrap," by A. L. Stillman, General Briquetting Co., New York City.
"The Swelling of Zinc Base Die Castings," by H. M. Williams, National Cash Register Co., Dayton, Ohio.

Munitions, Etc.:

"The Present Status of Tin Fusible Plug Manufacture & Properties," by Dr. Geo. K. Burgess, and Gurovich, Bureau of Standards, Washington, D. C.
"Stellite," by Elwood Haynes, Haynes Stellite Works, Kokomo, Ind.
"Fire Prevention in Large Industrial Establishments," by C. W. Johnson, Westinghouse Electric & Mfg. Co., Pittsburgh, Pa.
"The Use of Die Casting in Munitions," by Chas. Pack, Doehler Die Casting Co., Brooklyn, N. Y.
"A Few Points on Alloy Patents," by Wm. J. Rich, Patent Office, Washington, D. C.
"Shrapnel Bullets," by Harold J. Roast, The Jas. Robertson Co., Ltd., Montreal, P. Q.
"Recent Industrial Uses of Aluminum," by F. G. Shull, Aluminum Co. of America, Boston, Mass.

Testing Non-Ferrous Metals:

"Some Comparative Tests on Test Bars and Actual Castings," by W. M. Corse (The Titanium Alloy Mfg. Co., Niagara Falls, N. Y.), Buffalo, N. Y.
"Analysis of Babbitts & Brasses," by E. W. Hagmaier, Buffalo, N. Y.
"Standard Test Bars of 88-10-2 and 88-8-4, being the result of co-operative work of six foundries; a new series of tests," by C. P. Karr, Bureau of Standards, Washington, D. C.
"The Expansion Coefficients of Alpha and Beta Brass" and "The Corrosion of Manganese Bronze under Stress," by Dr. Paul D. Meriea, Bureau of Standards, Washington, D. C.
"Corrosion of Brasses of the Muntz Metal Type," by H. S. Rawdon, Bureau of Standards, Washington, D. C.

"The Analysis for Cadmium in Brass," by Dr. F. Schramm, Bureau of Standards, Washington, D. C.

Metallurgy and Metallography:

"The Electrolytic Production of Antimony," by Prof. D. J. Demorest, The Ohio State University, Columbus, Ohio.
"The Electrical Properties of Some High Resistance Alloys," by Prof. M. A. Hunter, Rensselaer Polytechnic Institute, Troy, N. Y., and F. M. Sebast.
"The Amorphous Theory in Metals," by Prof. Zay Jeffries, Case School of Applied Science, Cleveland, Ohio.
"The Uses and Metallurgy of Antimony," by K. C. Li, Wah Chang Mining & Smelting Co., Inc., New York City.
"Development and Reabsorption of the Beta Constituent in Alloys which are normally of the Alpha Type," by Prof. C. H. Mathewson, Dept. of Mining and Metallurgy, Yale University, New Haven, Conn., and Philip Davidson.

Great Interest in Coming Chemical Industries Exposition

The exposition management reports that manufacturers, works managers, chemists and engineers all over the country are taking a very active interest in the Third National Exposition of Chemical Industries to be held in the Grand Central Palace, New York, week of Sept. 24, 1917. Numerous letters from men all over the American continent and from foreign countries as well, have been received at the Exposition offices.

The success of the former expositions have been heralded in European countries. This has stimulated these countries to seek a better knowledge of the remarkable growth of the American chemical industries.

While refraining from giving information on the nature of their exhibits, the information on hand shows that there will be a very great many in operation—not only to demonstrate what certain machines will perform but operations upon actual material showing actual manufacturing processes in many of the industries.

Exhibits from railroad companies, state, and land companies showing the natural resources available in their several sections for the chemical industries will be made. Not only will these exhibits show the resources in their natural state but in many cases, where such have been made, the samples of the finished materials they produce.

The U. S. Government through the Bureau of Soils will be represented and will have an exhibit illustrating the fertilizer situation, and more especially American sources of potash.

The program of the exposition published in part in the last issue bids fair to attract much attention. In one phase it will discuss the foreign trade opportunities that the American manufacturer now has presented to him, and how to gain and hold those markets. Another phase of the program covers the work of some of the war councils. It will be remembered that at the First Exposition Mr. Howard Gross was one of the speakers and there proposed a Governmental Tariff Commission. The appointment of that committee by the President is but of recent moment and it is an interesting thing to learn how that committee will operate. Dr. Grinnell Jones of Harvard University, who has been selected as chemist to the commission, will be one of the speakers. It is not unlikely that Dr. F. W. Taussig, the chairman of the commission, will be another speaker to enter into the national operation of the commission for all the industries, while Dr. Jones' discussion will be confined to the chemical phases of the commission's work. It is undoubted that these addresses will be of great importance to the chemical industries, supplying them with much valuable information as to what they may expect, and as to how they could assist the commission making its work more thorough, to have a stimulating effect upon the productiveness of the American chemical industry.

There will be a symposium upon the national resources at which men thoroughly familiar with them will discuss the great existing opportunities.

Tentative Program

Monday, Sept. 24.—Opening day.
- Opening addresses by Dr. C. H. Herty, Dr. Julius Stieglitz, President American Chemical Society; Dr. C. G. Fink, President American Electrochemical Society; Dr. G. W. Thompson, President American Institute of Chemical Engineers.

Tuesday, Sept. 25:
- Prof. M. T. Bogert, Chairman, Chemical Committee, National Research Council, "The Operation and Work of the National Research Council for the National Weal."
- Dr. Grinnell Jones, "The Tariff Commission and Its Operation with Reference to the Chemical Schedule."

Wednesday, Sept. 26:
- W. S. Kies, Vice-President National City Bank, "The Development of Export Trade with South America."
- Dr. L. H. Baekeland, Naval Consulting Board, "The Future of the American Chemical Industry."
- Meeting of the Technical Association of Pulp and Paper Industry.

Thursday, Sept. 27:
- Symposium on National Resources for Chemical and Allied Industries, participated in by:
  - Mr. C. H. Crawford, Assistant to President of Nashville, Chattanooga & St. Louis Railway.
  - Mr. V. V. Kelsey, Chemist-Industrial Agent, Carolina, Clinchfield & Ohio Railway.
  - Dr. E. A. Schubert, Mineralogist-Geologist, Norfolk & Western Railway.
  - Dr. T. P. Maynard, Mineralogist-Geologist, Central of Georgia Railway & Atlantic Coast Line Railway.
  - Dr. J. H. Watkins, Geologist, Southern Railway.
- Meeting of the American Institute of Chemical Engineers.

Friday, Sept. 28:
- Meeting American Chemical Society, New York Section.
- Papers to be announced later.

The motion picture program will be announced later, though the following firms have placed their films at the use of the exposition managers: The American Cyanamid Company, Barber Asphalt Paving Company, E. I. DuPont de Nemours & Company, General Electric Company, Eagle-Picher Lead Company.

Production of Coal in 1916.—Statistics compiled by the Geological Survey show the total production of coal in the U. S. in 1916 to have been 590,098,175 net tons as compared with 531,619,487 tons in 1915. The number of employees was 14,000 less in 1916, but the number of working days was 26 greater.

The Principles of Filtration—II

By D R. Sperry

In a previous contribution* the fundamental law of filtration was deduced and found to be:

$$Q = \sqrt{\frac{2PKT}{R\%}+\left(\frac{KR_m}{R\%}\right)^2} - \frac{KR_m}{R\%}$$

In which:

P = Pressure.
T = Time of filtering.
K = Rate of deposition.
R = Resistance of the solids.
$\%$ = Per cent of solids in the mixture.
R_m = Resistance of filter base.

Another factor to take care of the effect of temperature was deduced and it was stated that two other factors might be added to allow for the effects of the squeezing together of non-rigid solids under increased pressure and to take care of the effects of gravity through the agency of settling or sedimentation.

The purpose of this article is to verify the fundamental equation of filtration by an analysis of actual time-discharge curves from a filter.

DERIVATION OF NECESSARY MATHEMATICAL TOOLS

Before it is possible to analyze a time-discharge curve from a filter a simple mathematical discussion is necessary.

Let us take the fundamental equation and simplify it by putting:

$$\frac{2K}{R\%} = W$$

and

$$\frac{KR_m}{R\%} = N$$

The fundamental equation then becomes:

$$Q = \sqrt{WPT + N^2} - N$$

If we take a time-discharge curve from a filter and select two points thereon such as (A) and (B) in Fig. 7, whose respective locations are T, Q and T_1Q_1 we know that

$$Q = \sqrt{WPT + N^2} - N$$

and

$$Q = \sqrt{WPT_1 + N^2} - N$$

Squaring each of these equations:

$$Q^2 + 2NQ + N^2 = WPT + N^2$$
$$Q_1^2 + 2NQ_1 + N^2 = WPT_1 + N^2$$

or

$$Q^2 + 2NQ = WPT$$
$$Q_1^2 + 2NQ_1 = WPT_1$$

Multiplying the first equation by $\frac{Q_1}{Q}$ and changing the sign we have:

$$-Q^2\frac{Q_1}{Q} - 2Q_1N = -WPT\frac{Q_1}{Q}$$
$$Q_1^2 + 2Q_1N = WPT_1$$

Solving these two equations simultaneously it is found that

$$Q_1^2 - Q^2\frac{Q_1}{Q} = WPT_1 - WPT\frac{Q_1}{Q} = WP\left(T_1 - T\frac{Q_1}{Q}\right)$$

or

$$WP = \frac{Q_1^2 - Q^2\dfrac{Q_1}{Q}}{T_1 - T\dfrac{Q_1}{Q}}$$

$\frac{Q_1}{Q}$ is the ratio of the discharges corresponding to the two points A and B, hence it is appropriate to represent $\frac{Q_1}{Q}$ by the symbol R, meaning ratio of the Q's. Inserting this symbol for $\frac{Q_1}{Q}$ in the foregoing equation there results:

$$WP = \frac{Q_1^2 - R_qQ^2}{T_1 - R_qT}$$

This equation is the mathematical tool which will be employed to verify the fundamental equation.

USE OF MATHEMATICAL TOOL

If the fundamental equation is true, as assumed, then any pair of points taken on an actual time-discharge curve from a filter should give, when substituted in equation H, the same value of WP regardless of where the pairs of points are selected.

If a number of pairs of points are used on the same actual time-discharge curve and the resulting WP's are approximately the same, the fundamental equation is verified.

APPLICATION OF THE MATHEMATICAL TOOL

In securing a time-discharge curve from a filter the readings are always plotted commencing with the first rushes of liquid. Since in any filter base there is an

*Metallurgical and Chemical Engineering, Vol. 15, No. 4, Aug. 15, 1916, page 198, by author.

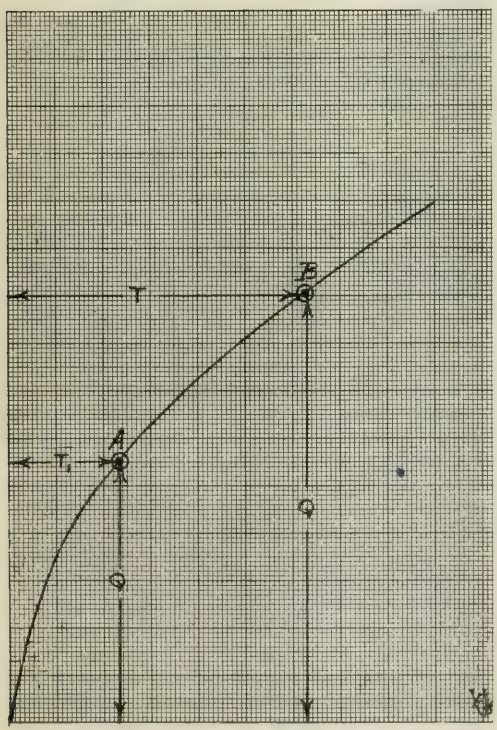

FIG. 7—TIME-DISCHARGE CURVE

initial loss of solids through the openings therein, it follows that the time-discharge curve would vary from that corresponding to the theoretical. The initial loss of solids is called "leakage" and the effect is to augment the total discharge.

Another cause of variation from the theoretical in a time-discharge curve from a filter is lack of constant pressure conditions. In the writer's own apparatus it is quite impossible with a hand-pump to keep the pressure constant during the first few moments of a run.

The mathematical tool, equation *H*, should not therefore be applied to the time-discharge curve from a filter in the form ordinarily obtained. Application to such a curve because of the above errors would be misleading, and the values of *WP* obtained therefrom would not be similar.

AN AXIOM OF FILTRATION

In an effort to overcome these seemingly insurmountable difficulties an axiom of considerable importance in the field of filtration was deduced, namely, that the time-discharge curve from a filter may have its origin at any corresponding points of *Q* and *T* and upon analysis will produce the same values of *WP* as though the origin was at the actual commencement of the run. In order words, in order to analyze a time-discharge curve we do not require the entire curve but only two points on the same.

FIG. 8—CONDITIONS AT COMMENCEMENT AND DURING RUN

To better understand this statement the following explanation is given:

In Fig. 8 is shown at (*a*) the conditions at the commencement of a run. At the moment shown the total resistance to flow is that of the filter base of thickness *A*. In the fundamental equation this resistance corresponds to *RM*.

In Fig. 8, at (*b*) is shown the conditions when the point of origin of the curve is taken at some time later than at the commencement of the run. Here the resistance to flow is that of the filter base plus that of the cake already deposited, or the total resistance through thickness *B*. This resistance also corresponds to *RM* of the fundamental equation.

It should now be evident that the fundamental equation holds whether the run is started at (*a*) or at (*b*), Fig. 8. In the first case the initial resistance is that of the cloth only (if the filter base is cloth) while in the second case the initial resistance is greater, equal to the sum of the resistances of the cloth plus that of the cake deposited up to the initial point. The conditions in the second case are the same as though a cloth of resistance equal to sum of the resistances of the cloth actually used plus cake deposited at the time under consideration were employed. Hence it is a matter of indifference whether a run commences at the start of the process of filtration or at some other point —the analytical results would be identical as far as *WP* is concerned. This fact is a matter of importance not only because the difficulties always attending the commencement of a run can be very easily avoided by its use, but also because one can analyze a discharge curve by taking only two sets of readings of time and discharge, both of which are referred to a common origin.

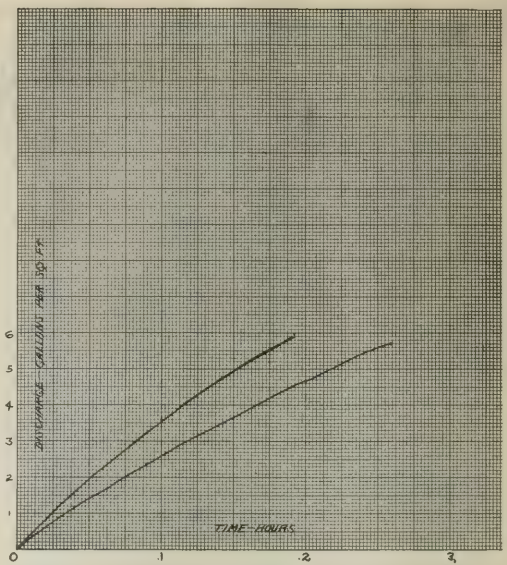

FIG. 9—TIME-DISCHARGE CURVES FROM SAME RUN, BUT HAVING DIFFERENT ORIGINS

In Fig. 9 are shown two curves from the same run, but having different origins. Should these two curves be analyzed for *WP* by means of equation *H* the two values of *WP* should be the same.

MIXTURE EMPLOYED TO PRODUCE THE ACTUAL TIME-DISCHARGE CURVES

In order to produce the actual time-discharge curve a working medium should be employed which will coincide with the assumptions upon which the fundamental equation is based. One assumption made is that the solids contained in the mixture are held in permanent suspension. A medium which has this qualification is of course impossible to find. It might be practical to obtain a liquid containing very minute solids in nearly permanent suspension, but to use it would involve the handling of large quantities of the mixture per unit of filtering area, a condition unsuited to the hand-operated apparatus available. After much consideration it was decided to employ a mixture of Kieselghur prepared in a manner calculated to minimize the effects of sedimentation. A thin mixture of this material and water was made and allowed to stand and settle for a period of one hour. Only the supernatant or unsettled portion was used in the run. It was assumed that since the supernatant portion had demonstrated its ability to stay in suspension for an hour, it would surely do so for a run which was less than one-half an hour in length. A little experimentation was carried out in order to ascertain what ratio of water to Kieselghur was best to use and how great a depth of the supernatnat liquor could be safely drawn off. Three 250 c.c. graduates were filled with different mixtures of Kieselghur and water. One had about a 2 per cent mixture, another

FIG. 10 — SHOWING THE THREE TEST MIXTURES BEFORE SETTLING

FIG. 11 — SHOWING THE THREE TEST MIXTURES AFTER SETTLING ONE HOUR

about 1 per cent and the last about ½ per cent. The contents of each was thoroughly agitated and then allowed to settle for a period of one hour. Figs. 10 and 11 show the appearance before and after settling. It was found that a portion of the solids settled to the bottom. The line of demarcation between this portion of the solids and the opalescent upper portion was quite sharp. There was no selective suspension of solids in the upper portion as far as the naked eye could detect. The distribution of solids appeared to be uniform throughout, producing a liquid of the same opalescence from the line of demarcation to the surface of the liquid. It was decided to use as a working medium for the test a liquor corresponding to the upper portion of the sample containing the smallest amount of solids. Measurements showed that about 14 per cent of the total mixture consisted of the dense portion.

For the test the water and Kieselghur were mixed together in a receptacle shown in cross-section in Fig. 12. After agitation the mixture consisting of 5⅛ oz. of Kieselghur and 8 qt. of water was allowed to settle for one hour. At the expiration of this period the upper portion was drawn from the lower portion by opening the drain valve. The height of the nipple inserted in the drain hole was such as to leave more than 18 per cent of the total mixture in the receptacle. This, according to the results of the test in the graduate given above, assured that none of the heavy mixture passed downward through the nipple and drain. It was found by a preliminary experiment that the nipple allowed 1½ out of 8 qt. to remain undisturbed.

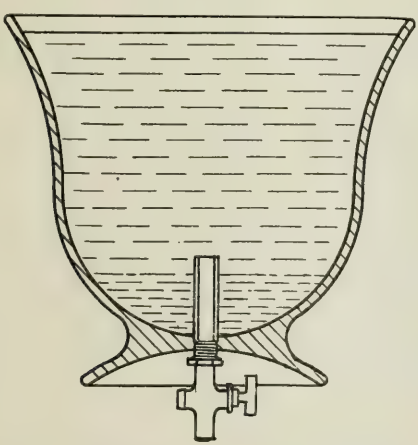

FIG. 12—CROSS-SECTION OF TANK SHOWING METHOD OF DRAWING OFF SUPERNATANT PORTION OF MIXTURE

The upper portion which passed out of the drain was used in the test. A pressure of 30 lb. per square inch was employed.

FILTER PRESS USED AND PLACE OF TEST

The apparatus employed is shown in Fig. 13, and arranged for this test as in Fig. 14. The frame measured 4 in. in height, and the mixture entered the upper head. The filter base consisted of No. 10 duck. Place of test, Basement Laboratory, 178 Union Avenue, Batavia, Ill. Date of test, Nov. 24, 1916.

OBTAINING THE TIME-DISCHARGE CURVE DATA

After agitation, the mixture stood in the receptacle from 2 p. m. to 3 p. m., after which the bottom drain was opened and about 6½ qt. of upper liquor drawn off and set aside in glass bottles. The above quantity was all that the height of nipple would allow to flow away. Next, the nipple was removed and the heavy liquor allowed to pass out. The receptacle was then rinsed, the drain closed and the upper liquor emptied therein from the bottles.

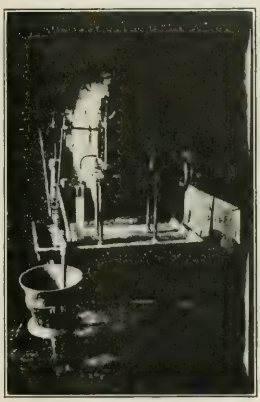

FIG. 13—FILTER PRESS AS USED IN THE FIRST TEST. THE STRAIGHT HORIZONTAL INLET PIPE AND THE CURVED OUTLET PIPE CAN BE PLAINLY SEEN

By opening and closing appropriate valves, the liquor was caused to circulate freely through pump and piping to make sure that nothing but the prepared mixture would reach the filter.

Before closing the filter and immediately preceding the run the frame was filled with liquor. This eliminated air pockets and caused each run to start at almost the instant pressure was applied. After closing the filter the valve to same was shut and the pressure to be used in the test built up in the pump and piping.

In starting the run the valve to the filter was opened and the pump started simultaneously, the pressure being maintained as constant as possible. A bottle was previously put in position to catch the issuing filtrate. At the expiration of the first time-interval the first bottle was quickly removed and another substituted with no appreciable loss of filtrate.

Pressure was kept constant by placing weights on the handle of the pump. This acted as a pressure regulator, making it only necessary to raise the handle

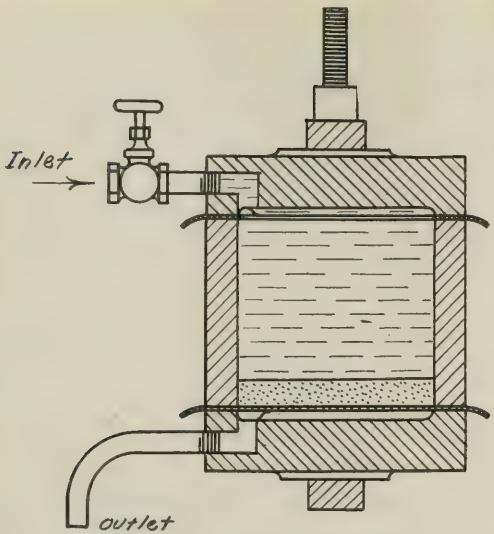

FIG. 14—CROSS-SECTION OF FILTER AS USED IN FIRST TEST

when it had descended by its own weight to a certain low position.

The pump used was a single-acting, outside-packed, 1½-in. x 3-in. plunger pump hand operated.

Simultaneous time and discharge readings were as follows:

Reading	Time	Interval Discharge in c. c.	Time Increment in Minutes
1	3 20	0	0
2	3 20¾	524	¾
3	3 22	339	1¼
4	3 23½	294	1½
5	3 25	233	1½
6	3 27	256	2
7	3 29½	272	2½
8	3 32	238	2½
9	3 35	250	3
10	3 38	236	3
11	3 41½	249	3½
12	3 45	233	3½

In order to arrange these data in a manner to avoid as much confusion as possible when equation (*H*) is applied, the first two columns in the following tabulation were computed from the data above.

Reading	Time Intervals in Hours	Interval Discharge in Gallons per Sq. Ft.	Total Time in Hours	Total Discharge in Gallons per Sq. Ft.
1	0	0	0	0
2	.0125	2.772	.0125	2.772
3	.0208	1.793	.0333	4.565
4	.0250	1.555	.0583	6.120
5	.0250	1.232	.0833	7.352
6	.0333	1.354	.1166	8.706
7	.0416	1.439	.1582	10.145
8	.0416	1.259	.2	11.404
9	.05	1.322	.25	12.726
10	.05	1.248	.3	13.974
11	.0583	1.317	.3583	15.291
12	.0583	1.232	.4166	16.523

Fig. 15-A is the graph of these data. This, then, is the time-discharge curve as experimentally determined.

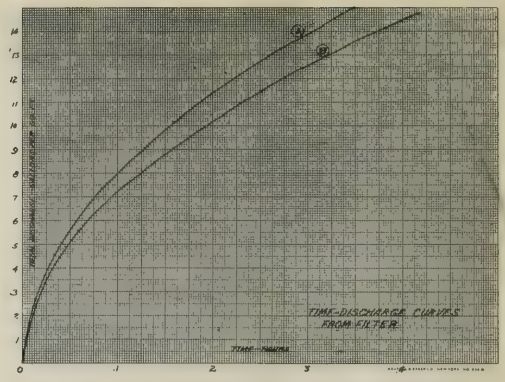

FIG. 15—TIME-DISCHARGE CURVES FROM FILTER

It now remains to apply equation (H) and see whether or not these practical results agree with the theoretical deductions.

APPLYING THE MATHEMATICAL TOOL.

Let us select the various origins at the points indicated by the zeros in the table below. The first origin is taken at run No. 4. This is done as previously explained to eliminate causes of error which are almost certain to exist in the first readings due to initial leakage and inconstant pressure conditions.

Reading No.	Origin No. 1		2		3		4		5		6	
1												
2												
3												
4	0	0										
5			0	0								
6					0	0						
7							0	0				
8									0	0		
9	.1916	6.608	1 666	5 375							0	0
10					.1833	5 269	.1416	3 83	10	2 571		
11											1083	.2566
12	.3583	10.4	333	9 174	.3	7 82	2583	6 38	2166	5 121	166	3 798

The top oblique line of zeros are the origins, both of time and discharge. Six pairs of origins have been taken in order that there may be six computed *WP*'s to compare.

In case the fundamental equation is correct, and the working medium fulfills the assumptions made, then all of the six *WP*'s should be the same.

The middle line of figures in the above table are the *T*'s and *Q*'s for each of the six origins, the *T*'s being the left hand figure of each pair. Similarly the bottom row of figures are the *T*'s and *Q*'s for each of the origins, the *T*'s being the left-hand figure of each pair.

The equation into which each of these six different sets of *T*'s, *Q*'s, T_1's and Q_1's are to be substituted in order to solve for the *WP* corresponding to each origin is equation (*H*) or:

$$WP = \frac{Q_1^2 - R_0 Q^2}{T_1 - R_0 T}$$

In the tabulation below the *T*'s, *Q*'s, T_1's and Q_1's are listed, the other factors deduced, and the *WP*'s obtained:

Factor	Origin No.					
	1	2	3	4	5	6
T	.1916	.1666	.1333	.1416	.1	.1083
T_1	.3583	.333	.3	.2583	.2166	.1666
Q	6.608	5.375	5.269	3.83	2.571	2.566
Q_1	10.40	9.174	7.82	6.38	5.121	3.798
Q^2	43.67	28.89	27.77	14.67	6.612	6.585
Q_1^2	108.30	84.1732	61.1539	40.7164	26.2316	14.4319
RqQ	1.574	1.706	1.483	1.665	1.991	1.48
RqQ^2	68.77	49.3161	41.2165	24.4464	13.170	9.74857
RqT	.301848	.284428	.27225	.23598	.19917	.1603
Q_1^2—RqQ^2	39.531	34.857	20.943	16.273	13.061	4.6824
T_1—RqT	.056476	.04891	.02745	.02235	.01756	.006289
WP	699.9	712.6	763.0	728.0	743.7	761.8

DISCUSSION OF THE RESULTS

A study of the results obtained shows that the value of *WP* for the origins is nearly but not quite constant. The greatest variation is very small. Plotting these values as shown in Fig. 16 at *A*, one is at once struck with the fact that such variation as occurs is a consistent one, the *WP*'s increasing in value the farther the origin is removed from the commencement of the run. This suggests that the variation is due to the changing of one or more of the constants represented by *WP*. Let us consider each of these factors as a possible cause of departure from the theoretical. As given previously:

$$WP = \frac{2KP}{R\%_c}$$

It is evident that either $2KP$ constantly increased or $R\%$ constantly decreased. *P*, the writer knows, did not increase as the pressure regulating device would not permit it. An examination of the dried cake shows in the fracture no strata or other evidences of a varying resistance. The trouble therefore probably lies in "*K*," the rate of deposition, or in "%" the per cent of solids held in suspension.

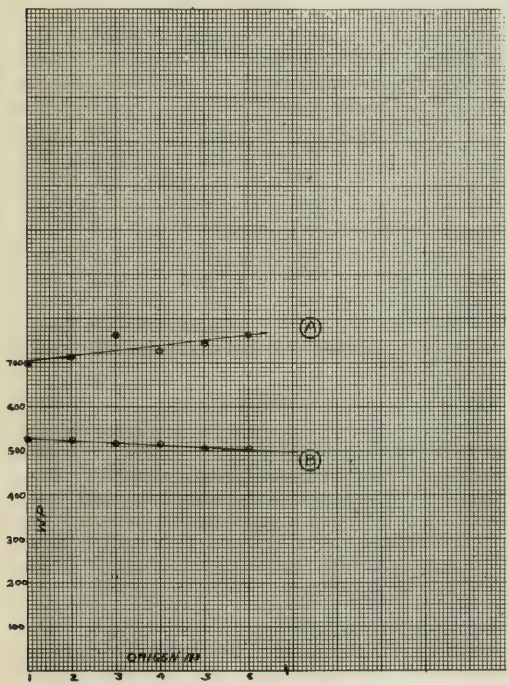

FIG. 16—RELATION BETWEEN *WP* AND DISTANCE FROM COMMENCEMENT OF RUN

SEDIMENTATION PROBABLE CAUSE OF DEVIATION

Sedimentation within the filter press during the run might well account for the apparent variation of these two factors. If such is the case the *WP*'s must be a very delicate measure indeed of sedimentation for it must be remembered that the mixture used was the supernatant portion of a mixture which had settled for one hour, while the run under analysis was only 25 minutes in length. The rate of settling in the mixture employed is undoubtedly approximately constant over a period of 25 minutes, while on the other hand the rate at which the cake is deposited by the process of filtration is not constant but decreases as the filtrate is discharged. In the case of origin No. 1 there was a certain thickness of cake already deposited at the start, at origin No. 2 a somewhat thicker cake had been deposited, similarly each succeeding origin has a thicker cake deposited at the start than the one preceding. Therefore the average rate of settling due to the process of filtration alone uniformly decreases as the origins are taken farther away from the commencement of the run, thus the total settling effect in each case is equal to the sum of the effect due to filtration, a decreasing quantity; and that of sedimentation, a constant quantity. The combined result being a decreasing sedimentation effect as the origin is taken away from the commencement of the run. This is in accordance with the results obtained and may therefore account for the variation. The effect is the same as though the rate of deposition *K* were increased or the per cent of solids %, decreased.

MEANS OF PROOF AS TO WHETHER SEDIMENTATION IS CAUSE OF VARIATION

Obviously if the *WP*'s increase as they are taken away from the origin when the settling effect due to

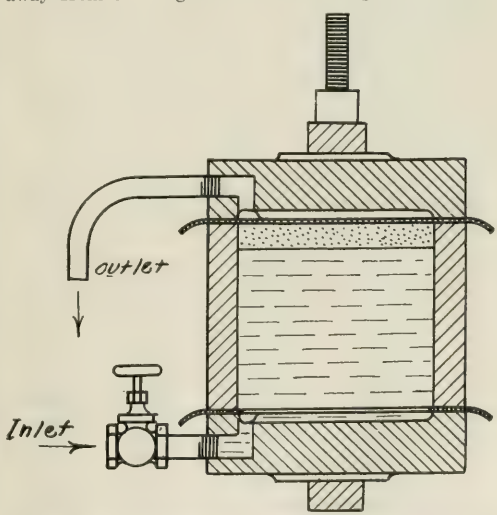

FIG. 17—CROSS-SECTION OF FILTER AS USED IN SECOND TEST

sedimentation acts in the same direction as that due to filtration it is to be expected that the *WP's* would do the opposite or decrease in value, as they are removed from the origin, in case the effect of filtration be caused to operate against that of sedimentation. If such is found to be the case it would serve to confirm the deductions already made, and tend to show that the fundamental equation is correct.

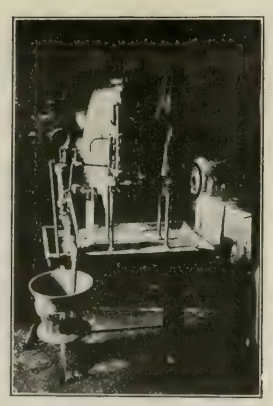

FIG. 18—FILTER PRESS AS USED IN THE SECOND TEST. THE RELATIVE POSITIONS OF THE INLET AND OUTLET PIPES AS COMPARED WITH FIG. 13 CAN BE EASILY NOTED

CAUSING SEDIMENTATION TO ACT AGAINST FILTRATION

In order to cause the settling effects of sedimentation and filtration to act against one another, the experimental filter press was arranged with the filter-base on the top side of the horizontal frame instead of below as in the first test. Fig. 17 shows a cross-section of the apparatus while Fig. 18 is a photograph of the filter press as used. The mixture employed was prepared precisely as was that used in the first test. The pump, the method of procedure and all else other than the location of the filter-base remained the same. Date of the test was Nov. 26, 1916. Mixture was settled from 3.35 p. m. to 4.35 p. m. Data readings were as follows:

Reading	Time	Interval Discharge in c. c	Time Increment in Minutes
1	4.46	0	0
2	4 46¾	470	¾
3	4.48	310	1¼
4	4 49½	258	1½
5	4.51	205	1½
6	4.53	228	2
7	4 55½	247	2½
8	4.58	215	2½
9	5.01	230	3
10	5.04	208	3
11	5 07½	221	3½
12	5.11	203	3½

Arranging these data as done in the previous test:

Reading	Time Intervals in Hours	Interval Discharge in Gallons per Sq. Ft.	Total Time in Hours	Total Discharge in Gallons per Sq. Ft.
1	0	0	0	0
2	0125	2 486	0125	2 486
3	0208	1.678	0333	4 154
4	0250	1 365	0583	5 519
5	0250	1 084	0833	6 603
6	0333	1 206	1166	7 809
7	0416	1 306	1582	9 115
8	0416	1.137	2	10 252
9	05	1.216	25	11 468
10	05	1 10	3	12 568
11	0583	1 169	3583	13.737
12	0583	1.074	4166	14 811

In Fig. 15 at *B* is shown the graph of these data. The fact that this curve is somewhat lower than that of the first test is doubtless due to a slight difference in the mixtures, the method of preparation permits a certain amount of error.

Arranging and selecting the origins in a manner similar to that done for the first test:

Reading No.	Origin No. 1		2		3		4		5		6	
1												
2												
3												
4	0	0										
5			0	0								
6					0	0						
7							0	0				
8									0	0		
9	.1916	5.951	.1666	4 867							0	0
10					.1833	4 761	.1416	3 455	.10	2 317		
11											1083	2.269
12	3583	9.296	.333	8 211	.3	7 005	.2583	5 698	2166	4 571	166	3.343

Solving for each of the *WP*'s as done in the previous test, the following tabulation results:

Factor	Origin No. 1	2	3	4	5	6
T	.1916	.1666	.1833	.1416	.1	.1083
T_1	.3583	.333	.3	.2583	.2166	.166
$Q_.$	5.952	4.867	4.761	3.455	2.317	2.269
Q_1	9.296	8.211	7.005	5.698	4.561	3.343
Q^2	35.43	23.69	22.67	11.93	5.37	5.152
Q_1^2	86.42	67.43	49.07	32.47	20.80	11.18

$R_Q Q^2$	55.33	39.97	33.35	19.68	10.81	7.59
$R_Q T$	.2993	.2810	.2697	.2336	.1968	.1595
$Q_1^2 - R_Q Q^2$	31.09	27.46	15.72	12.79	9.99	3.59
$T_1 - R_Q T$	.0590	.0523	.0303	.0247	.0198	.00707
WP	526.95	525.04	518.81	517.83	504.54	505.51

DISCUSSION OF RESULTS WITH INVERTED FILTER

Observing and plotting the *WP*'s, as shown in Fig. 16 at *B*, it can be noted that the values are nearly alike, the variation such as it is being a consistent one and precisely the opposite from that observed in the first test, viz.: decreasing as the origins are removed from the beginning of the run. This serves to indicate that the small variation from the theoretical *WP* is caused by a very minute sedimentation within the filter press itself and substantiates the fundamental equation for filtration as deduced in a preceding article.

In subsequent articles still more theoretical discussions are necessary before the solution of actual problems can be attempted. The foundation of a new science must first be built firmly in order that the superstructure of practical application will be upon a substantial basis.

Batavia, Ill.

The Wet Thiogen Process.—The Thiogen process for eliminating sulphur dioxide from smelter fumes and converting it into elemental sulphur, invented by Professor S. W. Young of Leland Stanford University and controlled by the Thiogen Company, has been described in this journal March 15, 1917, page 309. The Bureau of Mines has recently finished an investigation of the "wet" process and published the results in Bulletin 133, by A. E. Wells. The conclusions from this work were that in some localities the process can be carried out successfully for the recovery of sulphur and sulphur dioxide in waste smelter gases on a commercial scale and at a cost of about $12 to $13 per ton of sulphur produced.

Independent Laboratories in the Engineering Industries

By Clayton H. Sharp

The importance of laboratory work in connection with our national industries is more and more recognized, and there is no little discussion of suitable ways and means for promoting it. With the sharpened competition which must ensue at the close of the war which is now paralyzing the peaceful industries of the world, any and all means for increasing our industrial efficiency will be considered with a care which the easy-going times of the past has not accorded to them.

Our great manufacturing organizations are for the most part quite awake to the fact that laboratory testing and research are necessary and indispensable adjuncts to the growth and development of their industries. They realize that it is to the laboratory that they must look for radical or fundamental advances in the materials, methods and processes of production. They have established splendid laboratories and have attracted to them some of the greatest scientific men of the country. The product of these laboratories has been of enormous value—a value which cannot be measured in money, for it includes engineering and scientific discoveries which become the permanent possession of the human race and add to the prosperity and happiness of all future generations.

The manufacturers of smaller resources have not, however, made a correspondingly large use of laboratory assistance. This may be ascribed to two causes: first, that they have not been so fully aware of their own need for laboratory assistance and of the possibilities of laboratory work in increasing their efficiency, bettering their product, and broadening their scope; and second, because of practical difficulties in securing laboratory facilities which correspond to their needs. This paper is intended primarily to deal with the latter phase of the situation.

Laboratory or research work is commonly divided into two classes, both of which are important in connection with our national industries. First, there is the work in "pure science"—primarily the work of the university. Second, there is the work in "applied science," or in industrial research. Dr. J. J. Carty[1], in his address as president of the American Institute of Electrical Engineers, has very clearly and aptly drawn the distinction between research in pure science and research in applied science when he said that it lies neither in the subject matter, which may be identical, nor in the methods, which may the same, but in the motive. To quote his words:

> "Industrial research is always conducted with the purpose of accomplishing some utilitarian end. Pure scientific research is conducted with a philosophic purpose, for the discovery of truth, and for the advancement of the boundaries of human knowledge.
>
> The investigator in pure science may be likened to the explorer who discovers new continents or islands or hitherto unknown territory. He is continually seeking to extend the boundaries of knowledge.
>
> The investigator in industrial research may be compared to the pioneers who survey the newly discovered territory in the endeavor to locate its mineral resources, determine the extent of its forests, and the location of its arable land, and who in other ways precede the settlers and prepare for their occupation of the new country."

Evidently the industrialist who, to carry the analogy further, may be likened to the settler in the new territory, is dependent upon both classes of investigators; on the investigator in pure science because it is he who indicates the existence of a field heretofore unknown; on the industrial investigator because it is he who discovers the commercial possibilities which the field contains.

Further, the organization which is pre-eminently fitted to carry on the primary work of pure scientific investigation is the university. We must look to the university to discover and to foster the men having those rare and peculiar gifts of imagination, of transcendent patience, of unselfish devotion, which go to make up the explorer into the unknown regions of physical and chemical science. It is the university which must furnish these men the surroundings and the facilities which are required for the prosecution of their work.

For the adequate pursuit of industrial research, however, it is necessary to look to organizations constituted differently from the university. Industrial research having as its end the accomplishment of a definite result of commercial value accruing primarily only to the promoter of the work, it is evident that an institution organized like the university primarily for an educational purpose, and supported largely by endowments or by public funds, cannot justly devote any considerable portion of its energy or resources to any purpose which is not for the benefit of the public at large. The technical schools in this respect are in the same class with the universities with the important exception that a technical school is in general better situated for the conduct of industrial research work than is the university from the fact that its activities are along industrial lines. Hence we find that many of the great industrial corporations in this country have, as has been said, met their own needs by establishing their own private industrial laboratories. For the industries at large, however, this affords no adequate solution of the laboratory problem, for it does not apply to the multitude of concerns, individually smaller than the great corporations, but in the aggregate of enormous industrial importance. The importance of laboratory work to the smaller concerns is relatively just as great as to the larger ones (yet each by itself is unable to support economically and efficiently an adequate laboratory), and the problem is to find the best means of supplying their needs in this particular.

One possible solution is for the smaller manufacturer to take his laboratory problems to a technical school for solution. This plan, while it may work out admirably in many cases, is open to the objection which has been mentioned above, namely, that the funds of the institution, being given for a public purpose, should not be diverted to private ends. However, it may be urged that it is to the advantage of the technical school to accept a certain amount of industrial work, not only in research but also in testing. Such work necessarily brings both instructors and students into contact with certain practical problems of the outside industrial world, too often a world of

[1]Carty. Proceedings A. I. E. E., Vol. XXXV. page 1411. October, 1916.

which they know much in theory but little in practice. The effect of this contact cannot but be broadening and helpful to the technical school and to its students, and if this advantage is sufficiently substantial, the theoretical disadvantage of diverting the attention and the resources of the institution to a limited extent to matters which are particularly the affair of private individuals or corporations is more than counterbalanced. Added to this advantage to the technical school are certain others, among which may be mentioned that incidentally the inadequate salaries of the faculty may be augmented to some extent and the instructors thereby put into a position more nearly in accord with the demands which are made upon them. To the industrial concern a recourse to the laboratory of a technical school may offer the advantage of furnishing a service for a smaller expenditure than would be necessary if all of the overhead and incidental charges were included, which under similar circumstances a commercial organization would have to make.

As against the advantages so outlined there are certain disadvantages which must be given careful consideration and due weight. We have noted that taking on a piece of industrial work has the effect of bringing instructors and students into contact with practical industrial problems and thereby broadens their vision and increases their usefulness. To the industrialist who presents the problem, however, the very lack of knowledge of practical details very greatly lessens the value of the technical school as an organization for the accomplishment of his purpose. Every technical problem is surrounded by limitations and special conditions which may not appear to be of controlling importance (from an academic standpoint) but which if not given their practical weight annul the solution. Considerations of cost, of the intellectual and psychological limitations of workmen, of transportation, or market conditions, of company policy, of technical and commercial usage in the field—any or all of them may have their influence on the result. The technical-school men, if less in touch with practice, are evidently at a disadvantage in the solution of problems involving these elements. The technical school, being organized and equipped for purposes of education and not for purposes of testing or industrial research, is frequently at a disadvantage on account of the limitations of its laboratory equipment, or the amount of power available, and on account of the lack of a business or technical organization especially designed to prosecute industrial problems which it never was designed to handle, with promptitude, accuracy and engineering commonsense. It must be remembered that while many discoveries are made by laboratory experiments on a small scale, many of these are not applicable to industrial exploitation for the reason that elements which in small-scale experimentation are of negligible importance, often become controlling factors when the scale is changed to correspond to practical production. A chemist in his laboratory may effectually close a flask with a cork; a similar procedure does not apply at all to a spouting oil well. He may evaporate to dryness a dilute solution for the purpose of recovering a small residue and never once think of the gas which he uses in the process. If he were dealing, however, with the same operation on a scale ten thousand times as big, the matter of fuel and of containing vessel might offer insuperable obstacles to commercial success. Small-scale experimentation teaches but little regarding the proper design of a switch to open a high-tension power circuit. Hence apparatus which is quite adequate for the small-scale work of the college laboratory may be entirely inadequate when experiments are required looking toward the industrial application of a process.

In speaking of this feature of industrial work in educational institutions, Dr. Steinmetz[2] in a recent address said:

> "Unfortunately this limitation for research work in accordance with the available facilities is not always realized, and especially educational institutions not infrequently attempt research work, for which industrial laboratories are far better fitted, while research work for which the educational institution is well fitted, which the industry needs, but cannot economically undertake, is left undone."

Prof. James Swinburne[3], in a lecture on "Science and Industry," delivered at Kings College recently, has pointed out that the instructor in technology tends as time goes on to be less and less in touch with practical conditions and more and more of an academic scientist. In general this is because only those are likely to take up the teaching profession who have less taste for engaging in the practical work of industry and their own successors are as a general thing the less practical ones of their own students. The academic scientist, on the other hand, is a master of his subject, for his science like himself is academic, and in his own field he is pre-eminent. Thus the tendency of the technologist to become academic is a tendency for him to follow his own proper bent and to employ his energies in the direction in which they will be most effective.

Since to refer the problems of the industry to the technical schools for investigation does not offer a satisfactory solution of the problem, some other way must be sought. This may be found along the lines indicated by Dr. Carty when he said:

> "One of these is for the manufacturer to take his problem to one of the industrial research laboratories already established for the purpose of serving those who cannot afford a laboratory of their own. Other manufacturers doing the same, the financial encouragement received would enable the laboratories to extend and improve their facilities so that each of the small manufacturers who patronizes them would in course of time have the benefit of an institution similar to those maintained by our largest industrial concerns.
>
> "Thus in accordance with the law of supply and demand, the small manufacturer may obtain the benefits of industrial research in the highest degree and the burden upon each manufacturer would be only in accordance with the use he made of it, and the entire cost of the laboratories would thus be borne by the industries as a whole, where the charge properly belongs."

Thus is assigned to the independent laboratory an important place in the engineering industries in providing for the smaller manufacturer laboratory facilities comparable with those enjoyed by some of the great corporations. To fulfill properly these functions the independent laboratory must be adequately supported, properly manned and abundantly equipped. Its staff must be organized on broad lines. Its engi-

[2] Journal of the Franklin Institute, Vol. 182, page 711, December, 1916.
[3] The Electrician, London, Vol. LXXVIII, page 182, November, 1916.

neers must be familiar with the practical and commercial features, as well as the technical details of the work which they encounter. It must include physicists and chemists accustomed to look at the fundamental features of the problems presented and to bring to bear upon their solution the methods and the point of view which are inculcated in the university laboratories of research, for the application of fundamental scientific principles to the solution of the problems of industry underlies all true industrial research. The fees charged by such a laboratory must be adequate to cover not only all expenses, but to yield a sufficient profit as well, for "unless industrial research abundantly supports itself, it will have failed of its purpose."

In return for the fees so paid the industrial research laboratory must deal with its clients in a highly confidential manner, conserving for them individually all the results of the work for which they are paying. It must be prepared to turn over to its clients the inventions and patents which are the direct outcome of any specific piece of work. It must organize its work efficiently, so that its costs are as low as is consistent with good work and so that the results are obtained without undue delay. As to equipment; this undoubtedly must be large. The variety of problems which will be brought to it will be of such scope that a great variety of instruments for measuring and for manipulation must be at hand. A very large supply of electrical power is an absolute requisite. These very conditions interpose serious obstacles to the establishment of laboratories of this character. Unless it is organized through the cooperative efforts of a considerable number of industrial corporations operating in the same or in similar fields, a difficulty is sure to be encountered in insuring beforehand its proper support. To some extent a laboratory of this sort must from its very inception possess an equipment representing a very considerable investment. Unless, therefore, the financial support is insured beforehand, no little faith is required on the part of those investing their money in it. When, however, it has been possible to establish a laboratory of this character, the scope of its work may be very large. It may, and should, include not only industrial research proper but ordinary and routine testing, such as is required by manufacturing concerns, by consulting engineers, and others. It should be prepared to make acceptance tests of manufactured articles on behalf of purchasers and a considerable part of its activities may lie in this direction. It should offer facilities to engineers, inventors, and experimenters to carry on laboratory work of their own under its roof and should make available to them all its own facilities.

In carrying out work of this great scope in an adequate and proper manner the independent laboratory will find itself side by side with the technical school as one of the potent features of industrial progress. The staff of such a laboratory would become increasingly efficient through the practical solution of problems of many kinds. The apparatus and other equipment would necessarily take on a diversified character such that new and unusual problems presented could be undertaken without the purchase or construction of special apparatus. As compared with under-equipped and insufficiently-manned laboratories which individual manufacturers might establish for their own use with a most laudable spirit, independent laboratories, supported by formal or informal co-operation, would be far more efficient both as regards the cost of maintenance, the character and extent of the equipment, and the practical results to the industries. In the last analysis the availability and utility of such laboratories depend on the amount of material support which the industrial world is willing to accord to them.

New York City.

By-Products in Electrolytic Copper Refining

By Lawrence Addicks

In a previous article on "Impurities in Electrolytic Copper Refining" (METALLURGICAL & CHEMICAL ENGINEERING, June 15, 1917) the various elements commonly associated with copper were discussed as impurities and their treatment carried far enough to get them out of the refined copper. We therefore left them as anode slimes and purifying plant salts or as furnace slags and flue dust. We have now to discuss the working of these impure metallurgical products into marketable materials.

MARKET

We may broadly divide the possible by-products into three main classes as to their probable disposition as: First, those which are readily marketable in any quantity which such sources are ever likely to supply; second, those which have a limited and therefore sensitive and widely fluctuating market, and, third, those which have at the present time practically no market at all. These groups consist of the following: first, gold, silver, platinum, palladium, lead, nickel and antimony; second, bismuth, arsenic, cobalt, selenium; and, third, tellurium.

Palladium is the only uncommon member of class one. The production of this element is as yet quite small and this amount is readily absorbed by the jewelry and scientific-instrument trade. Practically it has the useful qualities of platinum, but is of about half the density.

Bismuth goes chiefly into the drug trade. Any large production of it floods the market and depresses the price. It is seldom associated with copper in any quantity, although it is the mainstay of electrolytic lead refining.

There is a large market for *arsenic*, which is used chiefly for its poisonous properties in insecticides, etc., but in recent years the great output of arsenious oxide recovered from smelter flue dusts has glutted this.

Cobalt is an element that has not yet found itself. The Canadian Government has conducted a wide investigation as to its possible uses, but aside from the use of cobalt oxide in the manufacture of smalt and for whitening yellow pottery and the use of the metal to give certain minor properties to cobalt-plated ware and cobalt alloys, no marked characteristic giving it a superior value to nickel has been discovered, and so far it has not been found possible to produce it at the price of nickel. Except in one or two notable cases, as in Katanga bullion, cobalt is not associated with copper to any extent.

Selenium was a rare element a few years ago; to-day

a single copper refinery could easily produce ten tons a month, could it be marketed. Its peculiar photo-electric property has not created any tonnage demand, and its only major use is for coloring ruby glass. This creates a steady but very moderate market.

Tellurium could also be produced by the ton, but there appears to be no reasonably extensive market for it. It would seem that the various plants producing selenium and tellurium could advantageously join in trying to develop wider markets for these elements by scientific research.

MARKET REQUIREMENTS

Gold is nearly always sold to the United States Assay Office. There are no requirements as to fineness, but the bullion is weighed, sampled and assayed by the Government. It is then purchased with a "gold check" on the Treasury Department for full value less certain refining charges. These charges are so adjusted that they are greater than those of an outside refiner, unless the gold is nearly pure; but the last traces of impurities are taken out by the government for less than it would cost others who are properly equipped. This is due to the fact that the government is not concerned with interest charges while the gold is in process, while the individual is very much concerned therewith. The result is that it is customary for the refiner to bring his gold up to perhaps 985 parts fine, the balance being chiefly silver (which is not paid for above 992) and sometimes small quantities of the platinum group of metals which are likewise forfeited.

Silver is largely exported to London in normal times because the English market is higher than the American by an amount usually sufficient to pay transfer charges. Under the present war conditions the freight and insurance on trans-Atlantic shipments has become so high that the profit in this movement has been wiped out, and America is beginning to make direct shipments westward to the market in the Orient.

The silver used locally goes to brokers, but little of the home consumption passing directly into the hands of the user.

The chief impurity in bar-silver is copper. For the American market it is customary to produce 999 fine, and for the English 998. As value over 998 is neglected in payments from abroad while penalties are exacted if it runs under that point, care must be taken to bring high grade electrolytic silver *down* in fineness. This is done when melting by the addition of copper wire in sufficient quantity to allow a safe margin above 998 for assay variations. Also, as only even quarter ounces are paid for it is customary to plug the bars with silver to a safe weight above an even quarter. The same result could be obtained by trimming but this would obscure any evidence of theft by trimming in transit.

Tellurium is the main metallurgical enemy of silver and must be thoroughly eliminated from it in order to prevent brittleness in subsequent rolling of the metal.

Printed schedules of the charges of the U. S. Mints and Assay Offices are periodically issued by the Treasury Department and may be obtained upon application. The points of chief interest to a copper refiner in the present schedule are: first, all deposits are subject to a melting charge of $1 per 1000 oz.; second, ordinary doré is charged 1 cent an ounce for parting and refining; third, gold bullion between 950 and 991.75 parts fine is charged 2 cents an ounce for refining while silver contents in such bullion above 992 fine are not paid for; fourth, metals of the platinum group are not paid for, although their presence in quantity will be reported for the information of the depositor, and fifth, government weights and assays control, the weights being to one hundredth of an ounce and the fineness to the nearest quarter-part.

The *platinum group* of metals are sold as a rule in crude shape as a sponge or powder, running 950 fine or better. In passing, it may be of interest to state that the ordinary assay methods for the platinum group give very inaccurate results and that a true assay for platinum and palladium is a tedious and costly operation, involving repeated precipitations in order to free the platinum metals from the last trace of lead sulphate and silver chloride.

Lead is seldom present in any quantity unless it is added in the cupeling operation in the silver refinery. Its market requirements are too well known to need discussion here.

Nickel is used first, as nickel sulfate or as a double ammonium sulfate in nickel plating; second, as anodes; and third, as shot or oxide for steel alloying. The crude sulphate of nickel, iron and copper produced by a purifying plant can be made into a reasonably pure sulphate by wet methods. This is then broken down by heat into oxide which is in turn reduced by carbon to metallic nickel in an electric crucible. Carbon-free nickel can be made electrolytically from this product if desired. Nickel anodes are generally alloyed with more or less iron, although conditions in the trade are improving in this respect with a corresponding improvement in the character of nickel plating. The production of pure nickel salts is very troublesome and should not be attempted unless unusually pure electrolyte is available as a starting point. One of the large manufacturers of this product had so much trouble in meeting the strict requirements of the trade that wet methods of production were abandoned and the salt produced by dissolving pure nickel.

Electrolytic nickel should run 99.80 nickel plus cobalt and should be free from carbon and oxides. The cobalt should not exceed 0.3 per cent and the sulphur should be very low. Small quantities of iron and copper are permissible and a little arsenic is generally present.

Table I gives some examples of the crude by-product salt as made by the refinery which is the raw material for by-product nickel; also analyses of commercial single and double salts as found in the market.

Table I Analyses of Nickel Salts

Source	Type	% Ni	% Cu	% Zn	% Fe	% Co	% As	% Sb	% Pb
A	Crude	25.32	0 82	0.19	3.10	. . . .	1.27	0.29	0 05
B	Single	22.34	None	None	0.002	0.016	None	None	.
B	Double	14.93	0.008	None	Trace	None	None	None	. .
C	Single	20.80	Trace	0.001	0 007	0 053	None	None	None
C	Double	14 80	None	None	0 003	0.067	None	None	None

An example of nickel made in the electric furnace from refinery by-product salt showed 98.98 per cent nickel, 0.29 per cent copper and 0.73 per cent iron.

Antimony is marketed chiefly in "metallic" form as its principal use is in the manufacture of alloys. It should be sufficiently pure to show clearly marked

"stars" on the surface of the pigs. It can also be marketed as a "hard" lead.

Bismuth is produced as metal in very pure form, usually obtained by electrolytic refining.

Arsenic is marketed as a 99 per cent arsenious oxide readily obtained by sublimation from many flue dusts.

Cobalt is marketed almost entirely as oxide. There are three oxides of cobalt and all have a market demand. They are difficult to prepare and the trade requirements are based on previous production rather than on any rational specification. The great use of cobalt oxide is as an offset to yellow cast in clay and similar material, the powerful blue characteristic of cobalt salts being equivalent to a bleach.

Selenium is produced in granular or fused form, 99 per cent pure. The black variety, not too finely ground, is desired by the glass industry.

Tellurium is usually offered in an impure state but no market standards have as yet been developed.

METALLURGY

The general treatment of the electrolyte for the recovery of a crude nickel sulphate has already been discussed in the previous article noted above. This method also gave a cathode sludge of arsenic and copper from which a certain amount of arsenious oxide could be recovered if desirable. The balance of the impurities were either lost in blast furnace slags or concentrated in anode slimes.

The analyses given in Table II are representative of such slimes. The wide variation in the composition is due to different conditions obtaining at different

*Burns—Trans. A. I. M. E., Vol. XLVI, page 712.

plants and this lack of a uniform product has been one of the difficulties in the way of a wet treatment of slimes. *A* is an ordinary slime with nothing unusual in the composition. *B* is produced by the electrolysis of converter anodes; its nature is reflected in the high copper and sulphur contents. *D* and *E* are analyses after the slime has been somewhat oxidized and leached with dilute sulphuric acid to remove the excess copper; they show noteworthy amounts of selenium present. The high lead content of *E* results from anodes carrying 0.2 per cent lead.

There is room for division of opinion as to the exact compounds present in anode slimes. The silver, gold, and a large part of the copper in slimes from well-refined anodes are doubtless in metallic or alloy form. Selenium and tellurium may be present in elemental form or as selenides, etc. Lead is probably as sulphate and much of the nickel, iron, cobalt, arsenic, antimony and bismuth in some oxidized form, but antimoniates and analagous compounds as well as simple oxides may easily be present. In general the slime is in an oxidized condition since the prior processes in the converter, the anode furnace and during electrolysis are all strongly oxidizing. The less noble metals are all therefore more or less oxidized in the slime when drawn from the electrolytic tanks.

There is always a high percentage of copper present. In slimes from converter anodes this is due in part to undecomposed matte, but even in slimes from the purest anodes there is a considerable amount of very finely divided metallic copper to be found after all cathode needles, etc., have been carefully screened out. This probably comes from either mechanical disintegration of the anode under electrolysis or from chemical oxidation of cuprous salts formed at the anode. Any one interested in the various possible explanations of this action would do well to consult an article by Dr. Emil Wohlwill on anode disintegration in the 1903 volume of Zeitschrift für Electrochemie.

REQUIREMENTS FOR A SLIMES PROCESS

Perhaps the foremost requirement for a metallurgical process for the treatment of these complex slimes is that there shall be a minimum of loss of the precious metals. We are dealing with material which usually runs 35 or 40 per cent silver and half a per cent of gold (and at times much more). This means that every by-product must be retreated for values contained. The second question relates to the interest on metal value. The slimes are worth about $5 a pound and a process is needed which will turn out the great bulk of the gold and silver promptly. A third desideratum is to be able to recover as by-products any marketable impurities which are present in commercial amounts. Then we have to consider the chemical questions introduced in the parent process of copper refining by the presence of any unusual reagents. Finally we have to reckon with the operating cost of the process in question.

This problem of treating anode slimes is doubtless the most difficult presented by the metallurgy of copper refining, and it is also the one which to-day leaves most room for further improvement. It has always afforded a field of contest for advocates of wet against advocates of fire processes; and the methods used at present employ a mixture of the two, the wet processes, however, steadily encroaching as time passes. We shall first discuss present practise and then the possible points of attack for further improvement.

The general problem as at present handled involves three main steps: first, the production of a nearly copper-free slime; second, smelting this to doré bullion; and third, parting the doré.

SLIMES BOILING

As sulphuric acid is a cheap reagent and as sulphate of copper is the basis of the electrolyte, the obvious method by which to remove the copper from the anode slime is to convert it into sulphate. As copper is not readily soluble in dilute sulphuric acid, however, either strong acid or some oxidizing agent such as air or nitre must be used.

The practice in the earlier plants was to screen the slimes through 60 or 70 mesh copper wire into agitators, using water to force the slimes through the screen. These agitators were lead-lined tanks about six feet in diameter and six feet deep, carrying a two-bladed paddle 2½ in. from the bottom and driven 12 rotations per minute. The blades tended to raise the slimes from the bottom. A charge consisted of perhaps 1000 lb. of slimes. After these were sluiced down into the tank liquor was siphoned off and enough sulphuric acid added to make a 50 per cent solution. A steam pipe heated the charge to the boiling point, the paddles were started and 100 lb. soda nitre added, a few pounds at a time. Owing to the strong evolution of poisonous nitrous fumes the nitre was added only at night and the treatment extended over two and sometimes three nights when the copper was found to be reduced to perhaps 3 per cent. The liquors made were sent to the electrolyte after carefully settling to free them from slimes.

After agitating, washing, and settling the charge, the supernatant liquor was siphoned off and the slimes, now running about 60 per cent moisture, dried to a thick mud carrying 25 per cent moisture by means of closed steam coils. This mud was considered ready for charging into the reverberatory refining furnace.

This method has been subject to many variations in details. At some plants compressed air is used for agitation instead of the paddles. Drying has been accomplished by the use of filter presses, of centrifugals or by direct heat instead of steam. It remained the general method, however, until the development of cyclical purification of the electrolyte which system made objectionable the introduction of large quantities of sodium salts into the electrolyte.

This difficulty was first met by charging raw slimes high in copper directly into the doré furnace. As will be later explained, such a procedure locks up a large quantity of silver in circulating by-products and is very undesirable.

The next step was the development of slimes-roasting and air has now come into general use as an oxidizing agent. In some cases an ordinary roasting hearth is used and in others patented[1] forms of tray hearths, but in any case all that is necessary is to expose a shallow layer of slimes to a low heat with sufficient air passing to hold the temperature below the fritting point (the slimes often ignite and overheat from the heat of oxidation), while being very careful not to stir the bed, and produce dust losses. The resulting calcines are then leached with dilute sulphuric acid which readily reacts with the cupric oxide found in the roasting.

A third process, which is patented,[2] mixes the filter-pressed slimes with concentrated sulphuric acid in sufficient quantity to satisfy the copper present, and heats this mud in a furnace the hearth of which is a steel basin. The slimes and acid are mixed first and pumped into the furnace. The mass is heated to about 450 deg. Fahr. with an oil burner and the mud occasionally stirred. The residues are practically dry and yield their copper sulphate readily when digested in hot water. This operation uses but a chemical equivalent of acid which is an advantage in some cases.

These various oxidizing and leaching processes designed to separate the copper from the rest of the slimes can be made to bring the residues down to 1 per cent or less in copper, with careful handling. The other elements present are also more or less affected by the operation. During the process more or less silver sulphate is formed, but this at once reacts with the copper present to form copper sulphate and metallic silver. In fact boiling is generally continued until the presence of silver in solution is shown by a salt test. When a decided precipitate is shown a small quantity of raw slimes is added to precipitate this silver and it is then certain that sufficient work has been done to oxidize practically all of the copper. In roasting the more volatile elements sublime to a certain extent and such flue dusts are a fruitful source of selenium, for example. Solutions from the boiling tanks always show nickel, arsenic and antimony extraction.

SMELTING TO DORÉ

Whatever be the method employed in leaching the bulk of the copper from the slimes, the residue is always smelted to doré in some type of reverberatory furnace. Were the slimes subjected to a quiet fusion three layers of molten material would form with a distinct separation by specific gravity. At the bottom would be a foul doré bullion; in the middle would be what could be called a matte, silver being the principal metallic component and selenium substituting for the usual sulphur; then on top would be an arsenic-antimony slag.

Lime		1.075	0.18		

It is quite possible to base a process on such a fusion of raw slimes with subsequent separation and special treatment for the three resultant products. However, we should get but about half of the silver and most of the gold in a bullion around 900 fine, while most of the balance of the silver would be tied up in the copper-silver-selenium-tellurium matte. This matte is a troublesome material to handle without making undue losses or tie-up of silver, and it is because the quantity made is more or less proportional to the amount of copper present that it is desirable to eliminate this last element as far as possible before smelting.

The earlier work was done in cupels with the addition of lead, the process being in a cycle of charging, melting, skimming, cupeling with a blast, skimming and pouring. Something like 10 per cent of the lead used in this process would be lost, and the resulting slag

(Table III) would have to be retreated on a lead basis and therefore was generally shipped elsewhere.

Then the use of lead was abandoned in favor of straight reverberatory smelting in small basic furnaces, air being forced under the surface of the bath to promote oxidation. It is interesting to note in passing that the silver furnaces of to-day are as large as the copper reverberatories in the earliest refineries. The general plan of operations is to melt the charge, thin the first slag with such fluxes as silica, soda ash, salt cake, etc., skim, blow the small quantity of matte to a second slag and bullion, skim, fine the doré with air and nitre, skim, and pour. Table IV gives representative analyses of the various metallurgical products produced by such a procedure. While the various columns are not all strictly comparable, they are near enough so to give a good idea of the character of the products. Had not the matte made been charged back or broken down before skimming we should have had another product running about 26 per cent silver and 0.02 per cent gold.

It is interesting to note the relative concentrations of the various elements in the different products—the slimes produce roughly 30 per cent first slag, 15 per cent second slag, 30 per cent doré, and 20 per cent flue dust, plus volatile losses and minus fluxes and furnace material. Perhaps the most striking thing is the "spreading" of the silver-gold ratio, nearly all the gold going directly into the doré while the silver spreads over the various by-products. This ratio as the figures stand is as follows: Slimes, 52.2; first slag, 98.4; second slag, 806; doré, 40.6; flue dust, 29.3.

The gold content of the slags is quite satisfactory metallurgically, but the silver is entirely too high. When the slag is reasonably fusible, it is possible by desilverization—consisting of a melting and collection of the suspended values—to bring the silver down to 0.5 per cent, but as these slags are all retreated in the anode furnace this seldom pays.

The elements which do not readily form fusible slags and therefore float undigested on the surface of the bath and those (such as lead, iron, and antimony) which on the contrary form slags very readily, tend to concentrate in the first slag. It is such an impure and unpromising material that it does not offer much chance for the recovery of by-products. Were the nickel out of the way it could be reduced to an impure antimonial lead.

The second, or soda slag really represents impurities subsequently blown out of the base bullion and matte formed when the slimes were melted. Here we have a decided concentration of tellurium, an element which clings tenaciously to silver. Since sodium salts are generally soluble, over half the total contents of this slag can be leached out with hot water. This is the starting point for the recovery of tellurium.

The small quantity of nitre slag made when fining the doré is charged back into the furnace with the next lot of slimes.

The flue dust shows a remarkable concentration of selenium and it is from this source that the market demand is supplied. Elemental selenium may be readily prepared from this dust in several ways—by fractional sublimation, by leaching followed by electrolytic precipitation, or by leaching followed by chemical reduction. The last-named method is perhaps the most satisfactory. The leaching is generally conducted in the presence of hydrochloric acid and a strong oxidizing agent such as a chlorate and preferably exposed to sunlight. The resulting solution is strengthened in free hydrochloric acid in order to hold back the tellurium, and the selenium is then precipitated as a red powder by sulphur dioxide gas. This powder is melted and skimmed to a bright face, when it is cast into cakes as the black variety. If desired, the powder can be dried in an oven, the heat changing it to the black variety and the baked product then ground for the market. Selenium often runs 99.5 per cent Se and the chief impurities are lead sulphate, arsenic, antimony and tellurium. The lead content is the most difficult to control.

PARTING THE DORÉ

We have two well recognized methods available by which to part gold and silver—the sulphuric acid and the electrolytic. Both are in use and have their advocates but the latter has come into more general use chiefly on account of its greater cleanliness.

In the acid method, the doré is cast into slabs resembling waffles, the indentations giving additional surface for corrosion. The process is very simple, being the production of silver sulphate by the decomposition of strong, boiling, sulphuric acid by silver, sulphur dioxide being given off. The gold is left undissolved and is melted in a crucible, while the silver sulphate, which is readily soluble in excess of free acid, is precipitated upon copper sheets to form sponge silver which is washed and melted. The copper sulphate solution is sent to the copper-refining tanks.

The plant required is inexpensive—needing only a couple of cast-iron pots, a lead-lined tank and a crucible furnace—and the tie-up of values is short, being about 48 hours. On the other hand the process is dirty; hot sulphuric acid is hard to handle; and the fine silver cannot be brought below a third of an ounce in gold. Also, if the doré is high in gold, the acid attacks it slowly and it is necessary to inquart it.

The hot liquor from the kettles runs about 600 grams per litre silver and twice as much free acid. This has to be diluted with water before the silver is precipitated, and the tank house must be able to absorb this free acid. The kettles are fired up and boiled until no solid pieces of doré can be felt with a stirring rod. This takes about eight hours. The liquor is drawn off to a heated settling kettle to free it from entrained gold, fresh acid is added, and then given an additional boil to free the gold of silver. By washing the gold precipitate thoroughly before adding this acid it is possible to make 995 gold sand directly in the kettle. The silver sponge should run 998 or better.

The electrolytic process consists of the electrolysis of doré anodes in a copper-silver nitrate electrolyte. Three methods have been employed—the Thum-Balbach, the Moebius and the Whitehead. The first method uses horizontal carbon cathodes laid as the floor of a shallow earthenware tank, the anodes being carried in a basket within a light cotton bag to collect the gold slimes. At an efficiency of 90 per cent, 3.5 volts per cell is equivalent to a recovery of about 32 oz. silver per kilowatt-hour. The current density is limited to about 35 amperes per square foot by the heating of the electrolyte, as a hot solution means a high loss of free nitric acid.

The silver crystals have to be frequently removed in order to prevent treeing, which will reach and puncture the gold bag.

The electrolyte consists of about 4 per cent copper as nitrate, 2 per cent silver as nitrate, and 0.1 per cent free nitric acid. Copper enters from the doré and silver dissolves in a certain excess, nitric acid being regularly added, but the entrained liquor in the silver sponge removed holds the balance steady. The wash waters from this sponge are not returned to the parting tanks. There is no circulation of the electrolyte and each cell is a complete unit.

The silver crystals are readily washed with water and if the copper in the electrolyte is low, silver very close to 1000 fine can be produced. As this is not desired, however, the copper is allowed to build up to a maximum of perhaps 6 per cent in the electrolyte before any deliberate removals are made.

There is no anode scrap as the remnants of anodes are left in place on the horizontal trays until they are entirely consumed. Cathode silver runs 0.1 oz. per ton in gold or even better.

The gold mud is periodically removed and boiled in strong sulphuric and in nitric acids to remove the silver. This mud is also the raw material for the recovery of platinum and palladium, as mentioned later.

The Moebius process substitutes a vertical system of electrodes which is very much more compact and yields more silver per kilowatt-hour, due to lower tank resistance. The silver crystals drop to the bottom of the tank, in some plants being knocked from the cathode by a simple system of swinging wooden rakes. The anodes are inclosed in sacks. Against the cheaper first cost and somewhat lower power required, there is more care required to prevent gold leaks, the cell is not so open to constant inspection, and there is a small amount of anode scrap made.

The third system, which I have called the Whitehead plan, has not come into general use, although it has been more or less extensively employed at some of the government plants. It uses gelatin to obtain a coherent deposit to be stripped from silver cathodes and duplicates in many ways the conditions found in a copper refining cell.

As compared with the sulphuric acid method of parting, the products are more pure, there is less danger of metal loss, in a large plant the operating costs are somewhat lower, and but little by-product liquor is made. On the other hand the first cost of plant is much greater, in a small operation the operating costs are no lower, while the metal tie-up is at least 50 per cent more.

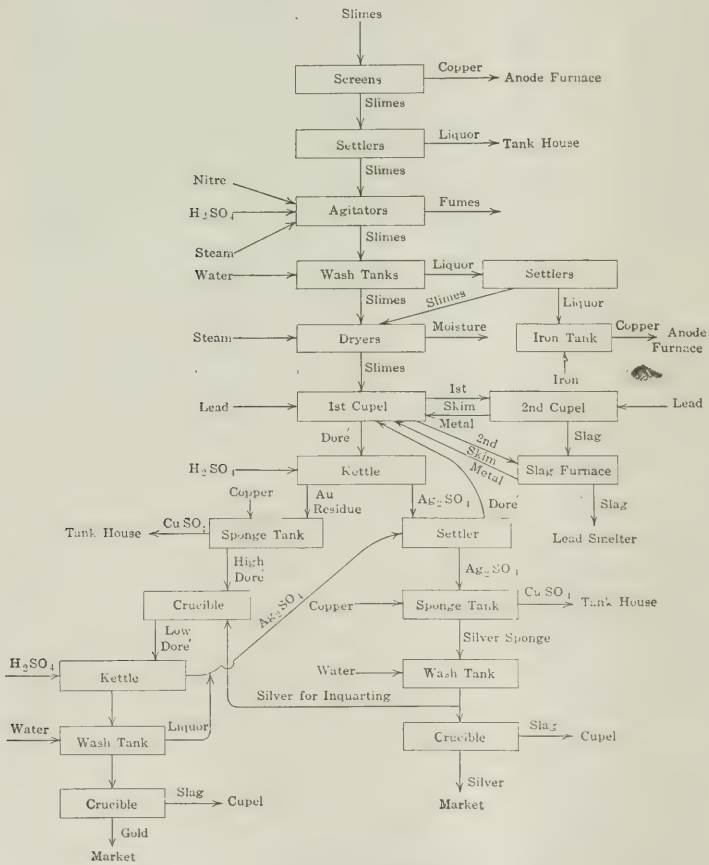

FIG. 1—SLIMES PROCESS 1900

If platinum and palladium are present in the doré we have the choice between electrolytic and chemical recovery. If the gold slimes from the parting are boiled to dissolve their silver in sulphuric acid, these metals remain with the gold which can then be electrolyzed by the Wohlwill process in a chloride electrolyte; if nitric acid is used in the gold boiling, the platinum and palladium go chiefly into solution and after a somewhat tedious treatment may be recovered as double chlorides with ammonium. The platinum is thrown out singly by sal ammoniac from a reduced solution; after oxidation the palladium may be similarly precipitated. Metallic sponges are obtained upon ignition of these precipitates. As these sponges are difficult to melt the metal is usually marketed as a crude powder. The separation between the two metals is quite sharp and a product 98 per cent or better is readily obtained.

The Wohlwill process has two great objections: it ties up a very valuable metal, and it exposes it to possible theft. In ordinary practice the gold does not ap-

pear in solid yellow metal until it is almost ready to ship. Crude, dirty products are hard to sell and do not present the same temptation to laborers handling them. On the other hand the electrolytic process is cleaner, as in the case of silver parting, with the result that most government plants use electrolytic and most private plants chemical extraction. As before stated, the government does not pay for platinum contents of deposits; one reason for this is that the assay method for accurate results is very tedious and expensive and its application would result in great delays in making settlements.

SLIMES PROCESS DEVELOPMENT

The progress already made with the metallurgical problems presented by copper anode slimes may be seen from Figs. 1 and 2 which are flow sheets representing practice twenty years ago and to-day. We may now consider the various points at which the second process may be attacked.

SCREENS

The fact that a certain part of the copper carried in the slimes may be removed by simple screening suggests the possibility of further separation by mechanical means.

The first point of attack here is against the size of the particle—could the slimes be classified in any way by screening? The practice at one plant is to screen out nodules and large pieces by passing the slimes through a 4-mesh screen, and then through a 70-mesh screen, which takes out float slime such as was discussed in Table VI in the last article[3]. Changing the size of this fine screen and then analyzing the slimes gave the results shown in Table V, below, which indicate the hopelessness of such a classification.

A screen analysis of slimes is given in Table VI. Here we happen to have a sample which has some small cathode debris present and the effect of screening this out is at once apparent upon the copper assays and the use of one fine screen is justified. In Table V the assay is for the total slimes passed by the screen while Table VI gives results for a true screen analysis. A 70-mesh screen will ordinarily retain 8 or 9 per cent of the weight of slimes sent it from the 4-mesh, and this quantity may be advantageously returned to the anode furnace.

As the silver and gold are presumably present in metallic form and as they have a higher specific gravity than most of the other elements present, some gravity separation might classify the product. Careful trials with a Wilfley table did not effect sufficient separation, however, to enable any process to be built on such a basis. It is just possible that the application of recent flotation experience might show something of value. It must be remembered that what is necessary is not so much a perfect separation—any process will have to work up its intermediate products for precious metal values—as a scheme whereby the great bulk of the silver and gold will be put on the market promptly, leaving

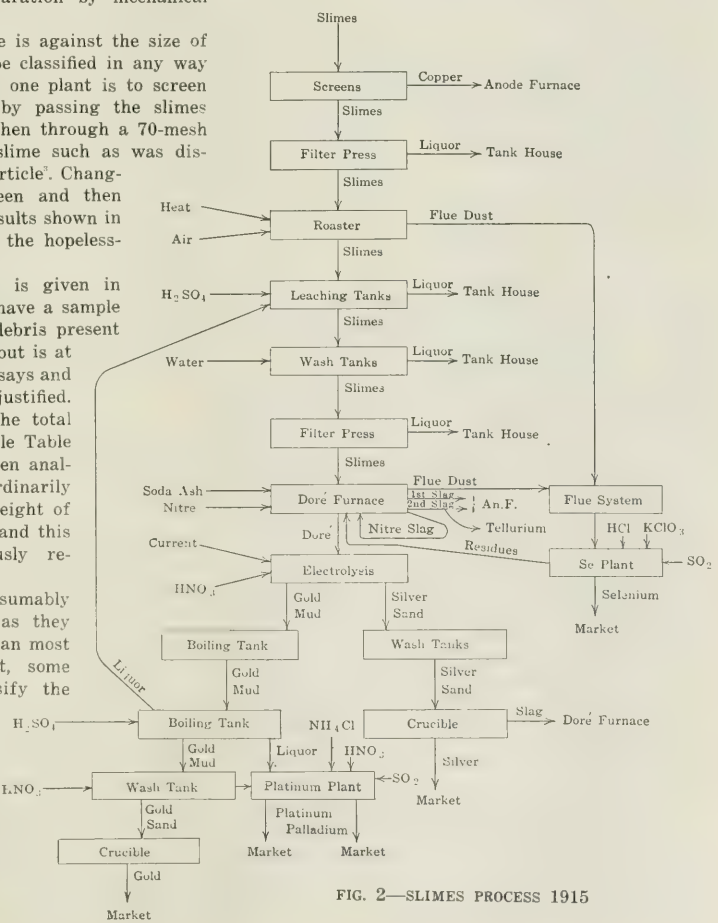

FIG. 2—SLIMES PROCESS 1915

the more tedious working of other by-products until the last. One of the objections to present practice is that the other elements are gradually removed until the pure silver and gold are obtained, thereby holding the entire value until the very end of a long process.

OXIDIZING THE COPPER

The next step in the present process is oxidation of the copper. It has already been pointed out that the presence of any quantity of copper in the doré-furnace charge makes a serious amount of by-product matte high in silver. If the copper is allowed to stand at 15 or 20 per cent and the slimes charged directly into the furnace, instead of obtaining 30 per cent first slag, 15 per cent second slag and 30 per cent doré we should get perhaps 35 per cent slag, 25 per cent matte and only 20 per cent doré, a third of the silver being tied up in the matte. The desirability of the awkward oxidation step has therefore been fully demonstrated.

In the endeavor to simplify this operation, considerable work has been done experimentally with ferric sulphate as an oxygen carrier using the well known reactions:

$$Cu + Fe_2(SO_4)_3 = CuSO_4 + 2FeSO_4$$

and

$$2FeSO_4 + CuSO_4 + \text{current} = Fe_2(SO_4)_3 + Cu.$$

A diaphragm cell is all that is necessary to carry out this process and chemically it is very pretty. The fact that it has not been successfully applied even in the hands of those skilled in electrolysis bears witness to the great difficulties interposed by a diaphragm cell in an acid process. Later work such as that of Hybinette in nickel or the use of a chemical retarder (Addicks, U. S. patent No. 1,138,921) may reopen this field.

LEACHING

The next step of dissolving the oxidized copper from the slimes is true leaching, and leads to the consideration of the possibility of dissolving the bulk of the slimes at once instead of making this a mere preparatory step to furnacing.

The first suggestive point to be noted is that in any of the oxidation processes it is easy to carry the action to a point where large quantities of silver may be taken into dilute sulphuric acid solution as sulphate. It is further known that by careful temperature regulation, a very high grade selenium product may be obtained in the flue. On the other hand, anything but an incipient roast tends to frit the easily melted slimes, spoiling the physical condition for subsequent leaching and forming undesirable chemical compounds of copper, arsenic, etc. Roasting therefore offers possibilities which are limited by difficulties in practical operation.

A second method of attack is to digest the raw slimes in boiling strong sulphuric acid. This readily dissolves nearly the entire content and yields a very foul solution of sulphates and an impure gold residue. Fortunately silver forms one of the very few insoluble chlorides and the plan would be to precipitate the silver with salt and reduce the chloride to metallic silver.

We have now a plan which would promptly yield the bulk of both the silver and the gold for marketing while leaving the less valuable constituents behind for working up into various other by-products. Such a plan may yet develop commercially but there are again some serious practical problems to be overcome. In the first place a certain amount of flour gold is formed and it is very difficult to keep this away from the silver chloride precipitate. If the latter is not free from gold it has to be parted, incurring corresponding delay and expense. Silver sulphate is not a readily soluble salt and a considerable bulk of valuable liquor has to be handled. The reduction of silver chloride can be done electrolytically or chemically but even that is not complete and the question of small quantities of chloride being volatilized during melting has to be considered.

On the gold side we have a sludge carrying lead and antimony as well as the gold, and this involves fluxes and slags in the refining.

The other elements are collected in a bulky, dilute solution carrying sulphates and chlorides and any simple separation is a chemical problem of no mean order.

SMELTING

Another possibility lies in directly melting the raw slimes in a furnace with separation of slag and matte leaving most of the gold and half to two-thirds of the silver in a doré bullion which can be quickly fined and parted. The slag can be returned to the anode furnace as at present and the matte subjected to some special process.

The direct blowing of this matte in a small Bessemer converter is the most obvious method. We would get a selenious oxide fume and a copper-silver blister as the products, which would be quite satisfactory metallurgically. The difficulty is in the lack of courage to face the probable silver losses. Now that the Cottrell process has been so successfully applied to silver flue losses (Aldrich Transactions American Electrochemical Society, Vol. XXVIII, p. 119) this might be reconsidered.

Another method is to pulverize this matte and leach the values, pre-roasting if desired. This really means leaching out the copper and we have simply rearranged the steps in the original process so as to more promptly release part of the values.

Smelting has the advantage that a fair separation of other impurities is made in concentrated form, easily stored for retreatment.

PARTING

This step is in a very satisfactory state of development and but little improvement in methods is to be looked for.

New York City.

Proposed Large Metallurgical Works for Spain.—At the general meeting of the Sociedad Española de Construcción Naval, recently held at Madrid, the directors proposed and were empowered to proceed with the preliminaries of a scheme for large works to supply the necessary material required by the national arsenals and the shipbuilding industry, such as forgings, castings, shapes, and special steels of every kind and copper, brass, and special bronze articles for which Spain has, until now, been dependent on foreign countries, and in the procuring of which the difficulties are increasing day by day. The aim henceforth will be that ships and war material must be built in Spain entirely of materials produced in the country, for which purpose large works with an annual output worth £1,000,000 are to be established with the technical co-operation of a British group at a cost of about £800,000.—*Iron & Coal Trade Review*, July 13, 1917.

Some Notes on Sulfonating Kettles

By Frederick Pope

In this discussion I will consider the various methods of controlling temperatures in sulfonating kettles, methods of agitation, and forms of kettles.

Sulfonating kettles are made of cast metal, for instance, cast iron or various acid resisting metals such as Duriron, Tantiron, Corrosiron, Buflokast, etc., the ratio of depth to diameter and shape of bottom varying widely according to the service required of the kettle. Kettles are ordinarily discharged either through the bottom or through a permanent or temporary tube inserted through the top, in which case air pressure is used to empty the kettle.

Fig. 1 shows a frequently used type of sulfonating kettle. The kettle itself is made of cast iron. The jacket may be either cast iron, or more often, boiler plate. Such a kettle is useful for such sulfonations as require either no external supply of heat, or a supply of heat at a low temperature.

Usually the source of heat is low pressure steam in the jacket, the steam being admitted through openings around the top of the jacket, and the condensation drawn off through an opening at the bottom.

This type of jacket is used when the source of heat is hot water, or when cooling water is used to control the temperature within the kettle.

When the kettle is heated by low pressure steam, a space of 1 to 2 in. between the outside of the kettle and the inside of the jacket is sufficient, but when hot water is used for heating or cold water for cooling, the space should be at least 4 in. These figures are for medium sized kettles, say in the neighborhood of 4 to 5 ft. in diameter. When either hot or cold water is used, care must be taken that it is introduced at a number of points, and drawn from a number of points to prevent hot or cold streaks in the jacket.

Steam jackets of this sort carefully designed and well built may be used for temperatures up to 130 deg. C. The jacket should be carefully insulated with asbestos or other non-conducting covering.

An example of a kettle of this sort is the one used in the sulfonation of benzol to benzol sulfonic acid, which is heated to a point between 80 deg. and 110 deg. C., depending upon the method used, and is equipped so that water may be admitted into the jacket for cooling in case of overheating.

When a higher temperature than 110 deg. C. is desired, we have a more difficult problem because if we use steam as our source of heat for heating the kettle, higher pressures are necessary, and we have the awkward problem of cylinders of large diameter subject to collapsing pressure from the outside.

A number of methods have been devised for solving this problem. Superheated water is successfully used abroad in place of high pressure steam. Fig. 2 shows one method of designing a kettle for high pressure steam. Here coils of wrought iron pipe are placed in the mold for the kettle, and cast iron is poured around them. It is reported that this construction is successful abroad, but according to available data has never been very successful in this country, the difficulty being the difference of coefficients of expansion between the wrought iron and cast iron. It presents a very at-

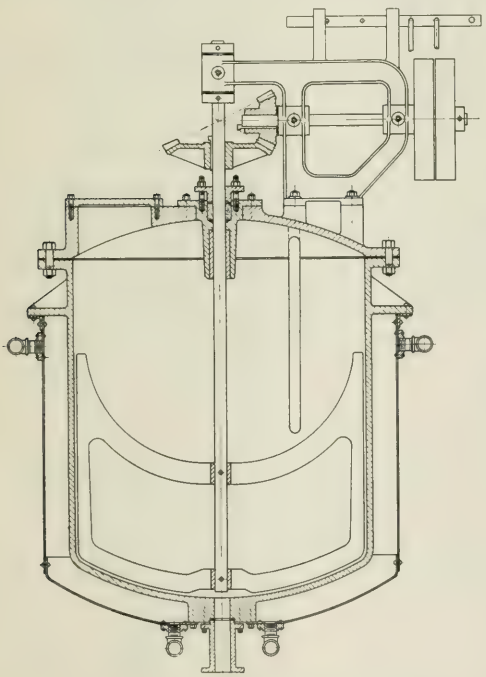

FIG. 1—CAST IRON SULFONATING KETTLE

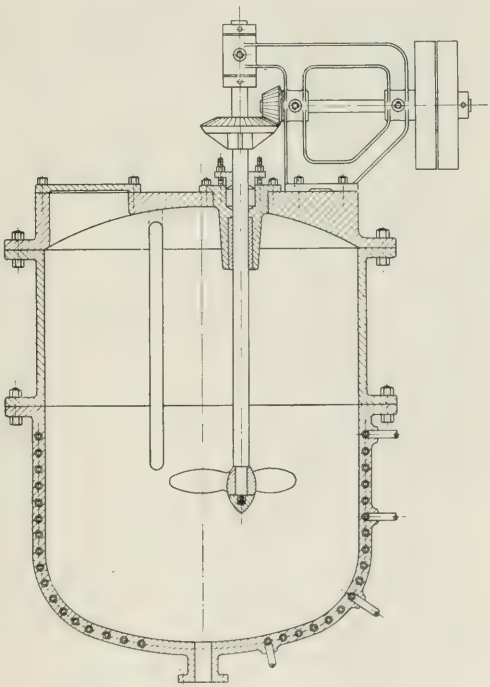

FIG. 2—SULFONATING KETTLE USING HIGH PRESSURE STEAM

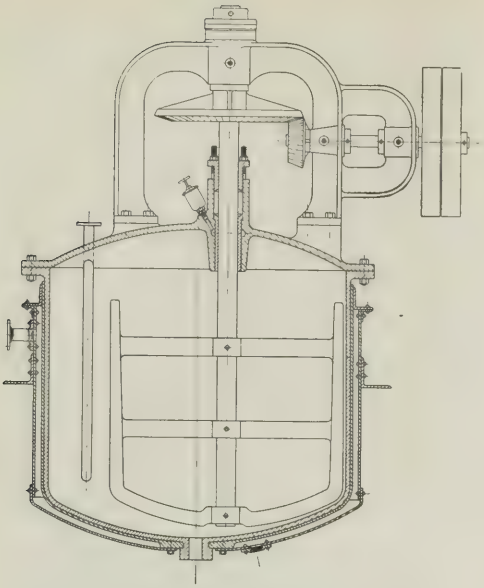

FIG. 3—ANOTHER METHOD OF USING HIGH PRESSURE STEAM

tractive method of heating if it can be worked out.

Another method of heating with high pressure steam is shown in Fig. 3. Steam at 125 lb. per square inch can be used in this jacket, the construction of which is very evident from the drawing. The jacket and inner shell are made of boiler plate, into which a lining of cast iron is poured.

Another method of getting high temperatures is to use superheated steam, the steam being at a low pressure. The objection to this method is the fact that one encounters innumerable well known mechanical difficulties. The objection to superheated steam besides the well known mechanical difficulties is the fact that the more highly steam is superheated, the nearer it approaches a gas, and the less becomes its weight per cubic foot. Both of these decrease its value as a medium of carrying heat.

A perfectly obvious way of obtaining high temperatures in a sulfonating kettle is to discard entirely the jacket and to heat the kettle directly, using preferably gas or oil for fuel, or to heat the kettle in a current of hot gas coming through a checkerwork, the checkerwork tending to give even temperatures, and to the avoiding of sudden changes up or down.

Another way is to surround the kettle with a steel jacket, forming an air bath. This method has been successfully used, but the thermal efficiency is not high.

The last method I wish to discuss for heating a kettle to a high temperature is by the use of some circulating medium, for instance, oil. In such a case we use a kettle similar to the one shown in Fig. 1, the oil entering a number of places in the bottom, and leaving through a number of openings spaced around the top. Such a system as this can easily be understood from Fig. 4 in which *a* is the sulfonating kettle, *b* the heating coil, *c* the circulating pump, *d* the expansion tank, and *e* the reflux condenser. The expansion tank should be equipped with steam heating coil to heat the oil before circulation is attempted. The first time the oil is used, the temperature should be raised gradually, as even the best circulating oil contains some water, which must be driven off before this system will work smoothly.

Temperatures up to 150 deg. C. may be maintained with the mineral oils available without serious deterioration of the oil. If it is desired to maintain a higher temperature than this, the oil circulating system should be provided with a reflux condenser to return to circulation anything that might be driven off from the circulating oil. When the system is equipped with reflux condenser, temperatures up to 250 deg. and even 300 deg. may be maintained.

A standard form of superheater re-arranged so that all the pipes are in series instead of some of them in parallel makes an excellent oil heater. The heater is preferably fired with oil or gas on account of the ease in regulation. This system should be equipped with a recording thermometer. In a well designed oil heating system, it is possible even when running a number of kettles from one heater to maintain the temperature within one or two degrees either way from a given point.

A sulfonating kettle is ordinarily equipped with a thermometer tube extending well into the liquid. It is always desirable to use a recording thermometer in connection with a sulfonating kettle.

A sulfonating kettle must always be provided with a cover to prevent loss of acid through evaporation or the weakening of the acid by abstracting water from the air. The cover may be of cast iron or boiler plate. The joint between the kettle and the cover is usually made either of lead or asbestos, although in some cases

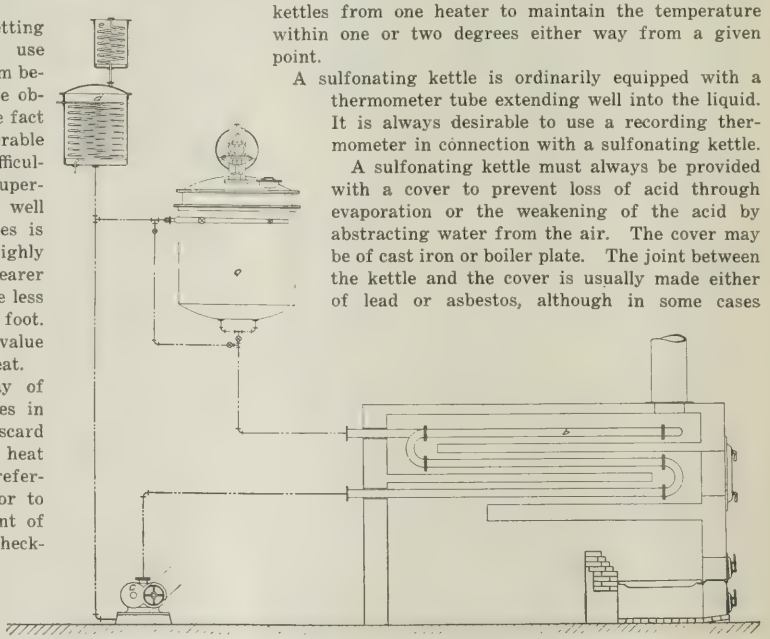

FIG. 4—OIL-HEATING SYSTEM

the cover is simply bolted to the kettle. The cover should have the following openings: A manhole as large as possible up to 12 in. by 15 in. or 14 in. to 15 in. diameter; an opening to admit sulfuric acid; in some cases a pipe connection to admit the material to be sulfonated, as for instance in a phenol plant, an opening for benzol, while in other cases, in making beta naphthol for example, the material to be sulfonated is charged through the manhole. In some instances, it is desirable to have an opening for a pressure gage or other form of manometer. If the kettle is not a bottom discharge, there is either an opening for inserting a temporary tube to the bottom or a permanent tube extending to the bottom, and an opening for compressed air for discharging the charge. It has been proposed to discharge the kettle through a hollow agitator shaft, but this is not recommended. There may be necessary an opening for the escape of fumes or for a condenser.

In the case of many reactions, often in the sulfonation of amino compounds, the reaction mass must be cooled in order to prevent undesired sulfonation of the compound. This cooling may be accomplished by either introducing water into the jacket if possible, or by having closed end pipes of enameled or acid resisting iron extending into the mass, and running cooling water or brine through these pipes.

The apparatus must be designed to meet the requirements of the reagent used. Ordinary pig iron, which is generally used, is not used with fuming acid, since it is quickly corroded by the high temperatures, which are often maintained for hours, in such a way that they accumulate gas in the little hollow spaces of the iron (hydrogen, carbon dioxide, etc.) which may disintegrate the cast iron. Wrought iron is strongly corroded by fuming acid up to 25 per cent free SO_3, at which strength it is again passive.

Various linings may be used. Enamel or lead applied directly to the inside of the kettle, or a chemise of nickel are used. The advantage of a nickel chemise is that when it is used up, it may be withdrawn and replaced by a new one.

Kettles have been built with horizontal stirring devices, but this is not desirable because of the difficulty in keeping the stuffing boxes tight when the shaft is in a bearing in contact with acids. It is also true that a horizontal stirring apparatus requires more power than a vertical one. A slanting stirring device gives uniformly good results, but for some undetermined reason is seldom used. The writer recommends it to the earnest consideration of users of sulfonating kettles.

Nearly all sulfonating kettles are provided with agitators of which there are a number of forms in use. The ordinary "U" type of agitator with the center line of the shaft coinciding with the center line of the kettle as shown in Fig. 3 is a common type, and for many uses very successful. This type of agitator is also used with the center line of the shaft parallel to the center line of the kettle, but a little off center, which gives a better agitation.

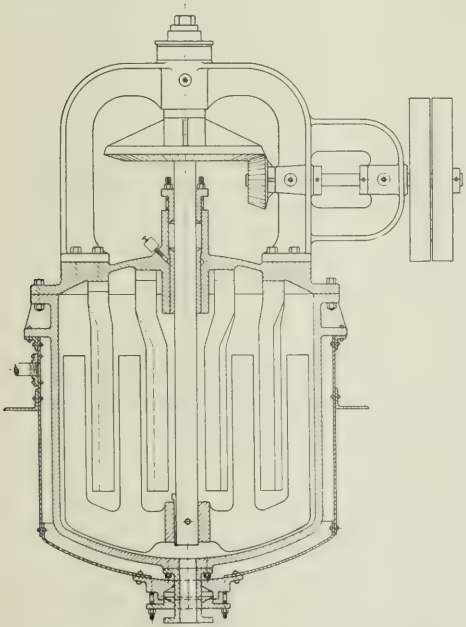

FIG. 5—KETTLE WITH SPECIAL TYPE OF AGITATOR

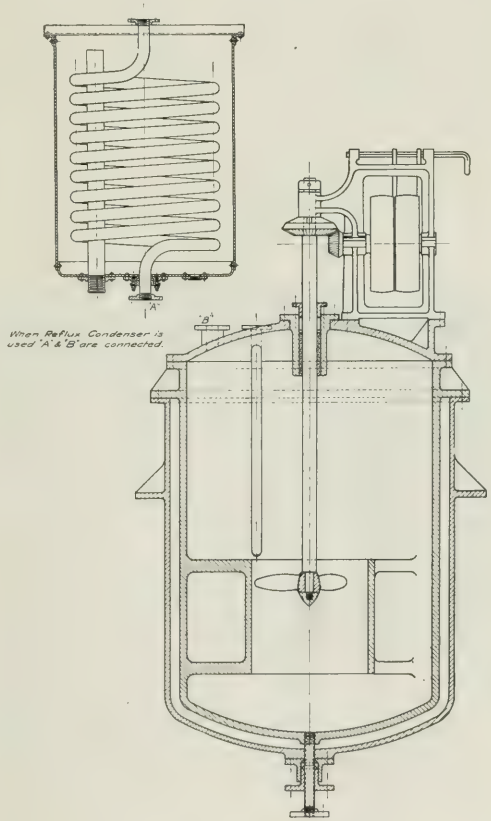

FIG. 6—KETTLE WITH PROPELLER INCLOSED IN TUNNEL

Another type of agitator which is very useful for certain purposes is shown in Fig. 5, which is really an elaboration of the "U" type. It is really a number of "U" type agitators with breakers.

The propeller is largely used as an agitator in a number of different ways, and although it is undoubtedly the ideal agitator under certain conditions, it cannot be used indiscriminately. There is one correct speed for the propeller type of agitator, which depends upon the size and shape of the kettle, size, form and pitch of the propeller, and the liquid in the kettle. A comparatively small variation from this speed will reduce greatly the efficiency of the agitating device. It follows that the propeller type is usually unsuitable in a sulfonating kettle in which the character of the liquid changes in the course of the reaction.

A single propeller is often used. A modification of this, considered by some to be an improvement, is to inclose the propeller in a tunnel, as shown in Fig. 6.

Another arrangement favored by many is two propellers on the same shaft, one propeller throwing in one direction, and the other in the other. Often these propellers have varying pitches. An arrangement of this sort well thought of in England has two propellers working in different directions with different pitches, with side breakers on the inside of the kettle, the shaft carrying the propellers revolving rapidly (250 r.p.m.). This is shown in Fig. 7. In certain work, it is reported to have been very successful.

In the opinion of the writer the best arrangement of the propeller is either one or two propellers; in case two are used, with varying pitches, and throwing in opposite directions, the shaft carrying the propeller or propellers parallel with the center line of the kettle, but a certain distance off center, as shown in Fig. 2.

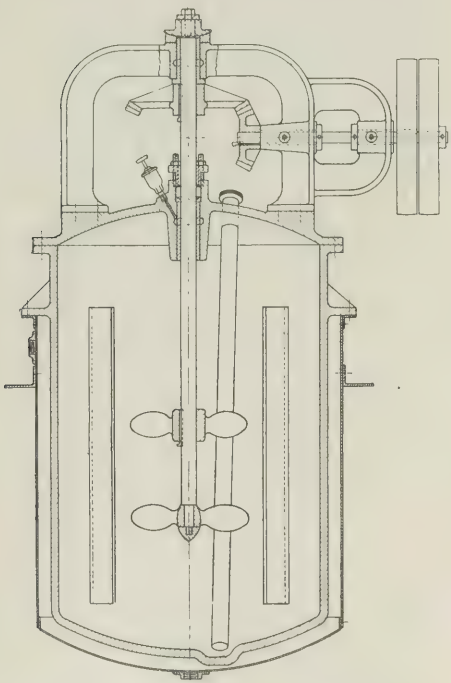

FIG. 7—KETTLE WITH TWO PROPELLERS ON THE SAME CHAIR

There are a number of special types of agitators for particular service used in sulfonating kettles. For instance, there are kettles built in which the shaft carrying one agitator is hollow, another shaft extending through the hole in the shaft carries another agitator revolving in the opposite direction. There are scraper types of agitators for particular purposes. In fact, the desirable type of agitator must be chosen in each case, and can only be determined by experience and study.

In a bottom discharge kettle, the design of the bottom discharge must be carefully considered. Many makers design a sulfonating kettle in which the discharge pipe passes through a stuffing box in the outer jacket and is screwed into the sulfonating kettle. For some uses, this construction is applicable, but often the screw threads are attacked by the acid, the threads in the casting being attacked as well as the threads in the discharge pipe. When the threads in the kettle have been destroyed, troublesome repairs are necessary. It is much better to introduce a spool piece between the kettle and the jacket as shown in Fig. 5. The valve controlling the discharge can be bolted directly to this spool piece.

Another method is to make the discharge pipe of cast iron with a flange cast on either end. The discharge pipe is bolted to the sulfonating kettle, passing through the jacket through a stuffing box. In this case it is necessary that the stuffing box and gland be split.

There has been considerable interest of late in continuous sulfonation, a number of schemes having been devised for the purpose. A step in this direction is sulfonation in two stages, which has been very successful in at least one large works.

Moses, Pope & Messer, Inc.
New York City.

Washington School of Mines.—The School of Mines was given an important place in the reorganization of Washington State College, at Pullman, Wash., by the board of regents at its last meeting and recently announced by President E. O. Holland.

Under the new plan, the mining end becomes one of the eight schools or colleges that comprise this state institution, and Prof. Francis A. Thompson, head of the mining department, becomes dean of the school of mines.

Full facilities will be available for instruction in, and treating ores by, all standard forms of treatment, including leaching, amalgamation, concentration, roasting and smelting. A special laboratory will be devoted to the flotation process.

Endowment of research on a large scale is the form that the memorial to the late Sir William Ramsay is to take. Five hundred thousand dollars is the amount mentioned. The interest on this sum will be devoted to the establishment of fellowships, which will be granted to mature investigators rather than to budding students. Ramsay was the most energetic and daring chemist that England has produced, and he deserves a substantial and generous monument in his remembrance.

Suggested Improvements in the Manufacture of Silica Brick*

By C. E. Nesbitt and M. L. Bell

The study of silica refractories is receiving more and more attention as shown by the increased number of articles appearing in the technical magazines. The published literature so far has dealt mainly with the theoretical study of the raw materials, while the practical side has received very little attention. Theoretical information is of extreme importance, but its importance is negative until put to practical use. The brick manufacturer is not as a rule a man of theoretical training, hence theoretical investigations to be of use to him must be expressed in simple and explicit terms, easily understood. This does not however excuse the maker, who in most cases has been negligent in regard to investigations of the properties and to improvement of his own product. The consumer has also been at fault in that he has not freely co-operated with the maker and informed him wherein the bricks failed. To obtain the best result it is necessary that these three —the investigator, the maker and the consumer— should work together with heartiest co-operation.

In the manufacture of iron and steel, silica brick find their greatest use in the open-hearth furnace. The demand here is for a brick of high refractoriness which does not become soft or plastic at working temperatures. The silica brick fulfills these requirements in that it is refractory and does not yield to compression unless the stress is sufficient to crush it. The ability of silica brick to stand when only a small portion of the original wall is left is well illustrated in the bulkheads. (Fig. 1.) This wall when built is 18 in. thick, but wears away in spots to less than 1 in. in thickness and still the brick retains its place.

In the by-product coke industry the development of the use of silica brick is interesting. Formerly a quartzite brick was used which was made of a mixture of clay and ganister. The object of the quartzite brick was to overcome the shrinkage and settling common to fire brick. Some twelve years ago silica brick were used experimentally in both beehive and by-product ovens. The experiment proved so successful that their use increased rapidly; not only did their expansion make a close, well-fitting joint and overcome settling difficulties, but their better heat conductivity greatly reduced the coking time. (Fig. 2.)

THE MANUFACTURE OF SILICA BRICK

In the manufacture of silica brick in this country the raw material used is quartzite rock commonly known as ganister. The important deposits are found in Huntingdon and Blair Counties of Pennsylvania, Devil's Lake region of Wisconsin, and in Alabama and Colorado. It is essential for high-grade silica brick that the ganister be hard and dense. The rock should analyze about 98 per cent silica, with 1 per cent each of iron and alumina. The raw material is broken to convenient size, dumped into a wet pan, and ground with water and lime. The degree of fineness and the amount of water is left to the judgment of the operator. This is a source of considerable variation, as it will be shown later that the degree of fineness has considerable influence on the strength of the finished brick.

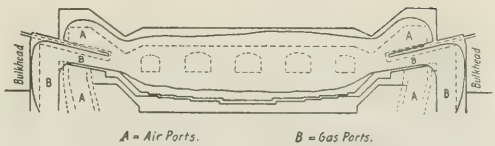

FIG. 1—VERTICAL LINES OF EROSION ON AN OPEN-HEARTH FURNACE

The binder commonly used is lime. Two per cent has been found to give the most satisfactory results. Percentages greater than this lower the refractoriness and decrease the strength of the brick, while percentages below 1½ per cent do not give a satisfactory bond. Binders such as iron, alumina, talc, water glass and other substances have been tried with more or less success.

The amount of water necessary to produce a satisfactorily working mud varies somewhat with the kind of rock used, amount of calcined material present and the method of manufacture. The percentage of moisture present is important. About 10 per cent of available moisture is the proper amount for hand-made brick. Too wet a mud will produce bricks and shapes which distort after being taken from the mold, while too dry a mud is responsible for a number of very serious defects, such as unfilled corners, sponginess, improper slicking, and lack of cohesion, all of which tend to give a finished product of low mechanical strength, susceptible to spall and slag penetration. (Figs. 3 and 4.)

The molding is a very critical point in the manufac-

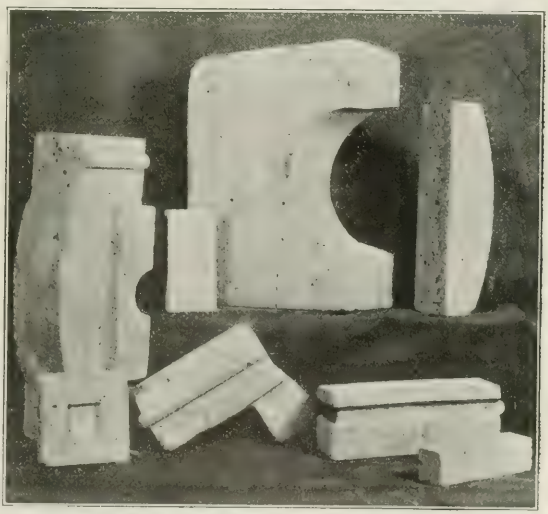

FIG. 2—A FEW DIFFICULT BY-PRODUCT COKE-OVEN SHAPES, ILLUSTRATING SHRINKAGE CRACKS AND CRACKS DUE TO RE-ENTRANT ANGLES—NOTE 9-IN. BRICK IN CENTER FOR RELATIVE SIZE

*A paper presented at the Atlantic City Meeting of the American Society for Testing Materials, June, 1917.

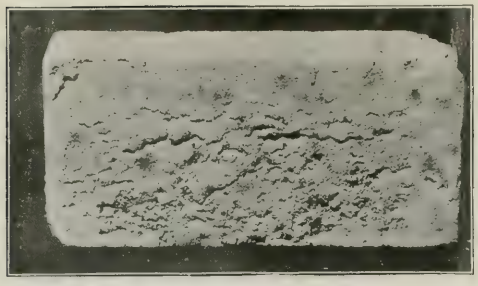

FIG. 3—AN EXAMPLE OF BAD MOLDING, POOR SLICKING, AND SPONGINESS

ture of silica brick. Improper filling of the molds, too wet or too dry mud, improper slicking, dirty palette boards, or careless handling, all contribute their share to the making of a defective product. The defects can largely be eliminated by close inspection and rejection of all but good bricks. As an illustration, bricks were received from a certain company which were poor in quality. The spalling loss was very high, running from 50 to 60 per cent. An investigation was made of the methods at the plant and irregularities of mixing, molding and burning were found. Careful inspection was applied to certain points in the brick manufacture, and to-day this same plant, with no radical change in its general method, is producing bricks much more uniform in shape, strength and appearance, and with a spalling loss of only 25 per cent.

Drying of the brick after molding is accomplished either on a hot floor, heated by steam, or in tunnels heated by hot air from the kilns. Drying on the floor is naturally the slower of the two methods, four to six days being required for 9-in. brick and proportionally longer for larger shapes, while drying in tunnels may be accomplished in eighteen to twenty-four hours. It is important that drying shall be done carefully and thoroughly, for unless the material is bone dry when placed in the kilns fire cracks are apt to result. (Fig. 5.)

The dried brick are set in kilns, which are usually of the down-draft type ranging in capacity from 50,000 to 150,000 bricks. It is important in setting that the bricks shall be true to shape in order that they have a proper bearing and stack well. Green bricks will not sustain a load of much more than 100 lb. per square inch, hence care should be taken not to overload them. Shapes should not be placed near fire boxes nor bear much weight. They are frequently boxed in.

Complete burning requires from ten to fifteen days, with a gradual increase in temperature until cone 16 is attained at least, (1450 deg. C.). The final temperature must be held a sufficient length of time to thoroughly and uniformly heat the entire kiln, which may require anywhere from one to three days, depending on the size of the kiln.

The cooling usually requires about five days and is accomplished by gradually opening the fire holes and doors until the bricks are cool, when they are removed and placed directly on cars or in the stock house.

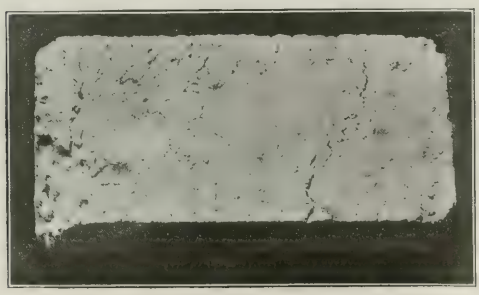

FIG. 4—AN EXAMPLE OF BAD MOLDING AND FIRE CRACKING

TESTS OF SILICA BRICK

With a view to studying the effect of degree of fineness of material and pressure, an experimental series of silica brick was made with these two factors as the only variables. A good quality of Pennsylvania ganister was selected and ground dry in three lots to pass a 12, 8 and 4-mesh screen respectively. To the ground material was then added the water and lime so as to give 9 per cent of moisture and 2 per cent of lime. From each of the above meshes standard 9-in. bricks

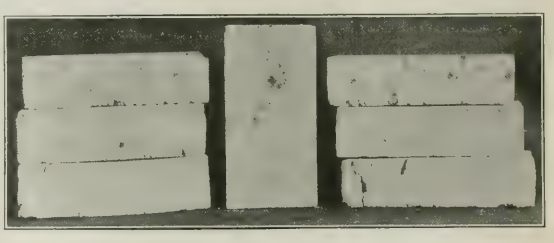

FIG. 5—CHARACTERISTIC FIRE CRACKS

were made on a small hydraulic press at eight different pressures varying from 187 to 2500 lb. per square inch. The bricks were dried, burned and cooled, following regular silica-brick practice, and were then subjected to certain physical tests to determine density, resistance to impact, resistance to spall, resistance to corrosive action of slag and expansion due to heating.[2] A summary of the results is given in Table I, in which the results of the three meshes are averaged according to pressure.

TABLE I—TESTS OF SILICA BRICK, ARRANGED ACCORDING TO PRESSURES

Pressure Under which Bricks were Made, Lb. per Sq. In.	Apparent Specific Gravity	Impact, In.	Percentage Spalled	Slag Penetration, Sq. In.		Expansion, Lin. In. per Ft.
				Open-Hearth Slag	Heating-Furnace Slag	
187	1.50	47	45.5	3.48	2.28	0.155
500	1.58	46	48.3	3.68	2.42	0.155
750	1.59	60	53.2	3.63	2.41	0.158
1000	1.63	65	51.4	3.79	2.42	0.190
1250	1.65	68	47.9	3.65	2.50	0.155
1500	1.66	65	43.6	3.82	2.50	0.160
2000	1.67	67	44.8	3.64	2.45	0.159
2500	1.68	71	42.0	3.72	2.50	0.160

Table II shows the results of the various pressures averaged according to mesh.

[2]The methods used are described in detail in this issue, page 184.

TABLE II—TESTS OF SILICA BRICK, ARRANGED ACCORDING TO MESH

Mesh	Apparent Specific Gravity	Impact, In.	Percentage Spalled	Slag Penetration, Sq. In.		Expansion Lin. In. per Ft
				Open-Hearth Slag	Heating-Furnace Slag	
4	1.66	57	30.4	3.92	2.63	0.156
8	1.62	63	47.6	3.67	2.39	0.159
12	1.58	64	63.2	3.44	2.29	0.159

TABLE III—LOSSES BY SPALLING, EXPRESSED AS PERCENTAGE

Mesh	Pressure Under which Bricks were Made, Lb. per Sq. In.							
	187	500	750	1000	1250	1500	2000	2500
4	21.9	34.9	37.9	38.7	31.4	30.4	19.1	29.1
8	51.6	45.9	62.6	51.0	43.3	34.8	38.3	43.3
12	62.9	64.0	59.2	64.4	69.1	65.8	67.0	53.6

Table I indicates that little is gained by increasing the pressure. Table II, however, shows the importance of the selection of mesh. It will be observed that the strength as indicated by the impact test is greatest with the fine-ground material, while the percentage loss by spalling increases with fineness of mesh. Two very important properties in first-class silica brick are the mechanical strength and resistance to spalling; hence from the data we must select a mesh at the expense of one of these properties. More is gained by the coarse mesh, hence we advocate for silica brick a coarse-ground material. (Fig. 6.)

Table III gives the individual losses by spalling for each pressure and mesh.

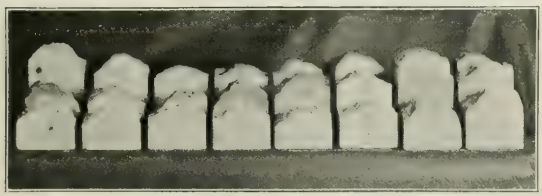

FIG. 6—SPALLING TEST ON EXPERIMENTAL SERIES—NOTE BRICKS IN ILLUSTRATION ARE AVERAGED WITH PRESSURE INCREASING FROM LEFT TO RIGHT AND MESH INCREASING FROM FRONT TO BACK. (TABLES I AND II ARE ARRANGED IN CORRESPONDING ORDER)

The average spalling loss for hand-made silica brick is about 30 per cent. From Table III it will be noted that power-pressed silica brick were made with the same spalling loss from 4-mesh material pressed at 1500 lb. per square inch. These bricks were true to shape, sharp-cornered, dense, and had smooth, marble-like surfaces. Molding defects such as soft corners, sponginess, improper slicking, and lack of cohesion were all eliminated. The prospect of the adoption of power pressing as a step towards better and more uniform silica brick was clearly brought out by this series of tests. The idea of power pressing is not entirely new, yet little has been done in a commercial way. One of the large concerns is now manufacturing brick this way on a commercial basis. The average spalling loss of these bricks is 25 per cent. (Fig. 7.)

In actual service, although well guarded as far as practice and construction will permit, silica brick fail from three primary causes: spalling, crushing and slagging. These cannot be entirely eliminated, but by a deeper study of the manufacturing of brick they can be reduced to a minimum. An ideal brick must be well molded, true to shape, thoroughly bonded, and of good mechanical strength. (Fig. 8.)

A visual inspection of almost any shipment will show at least 20 per cent of defective brick. Six shipments of brick of different brands brought out the fact that 60 per cent of the defects were due to molding, 30 per cent to fire cracks, and 10 per cent to improper setting and irregular shapes. These defects can be largely overcome in the present method of manufacture by careful inspection and rejection of the improperly made bricks at certain points in the manufacture.

The ganister must be carefully selected and sorted; all stock that is soft or which carries considerable iron, clay, sandstone or other foreign matter should be rejected. (Fig. 9.) The ganister selected should be ground to just pass a 4-mesh screen, care being taken to avoid an excessive amount of finely ground material. To insure uniformity, frequent sieve tests of the mud should be made. To secure a sufficient bond, 1.75 to 2 per cent of lime should be used. In order to avoid irregular

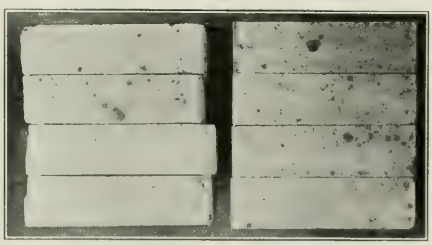

FIG. 7—COMPARISON OF HAND-MADE AND COMMERCIAL POWER-MADE BRICKS NOTE JOINTS

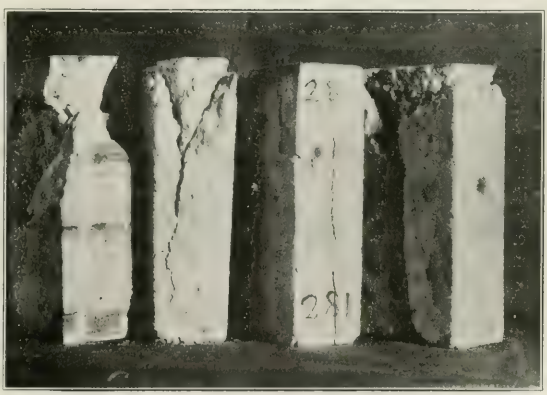

FIG. 8—CHARACTERISTIC CRUSHING TESTS

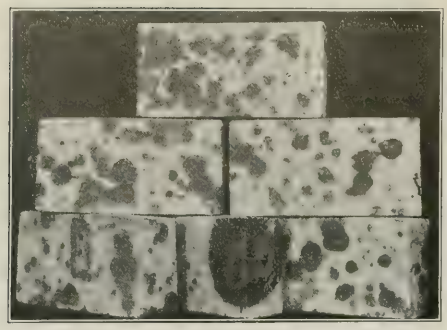

FIG. 9—DEFECTS DUE TO IRON IN RAW MATERIALS

shapes and molding defects, 9 to 11 per cent of water should be used for hand-made bricks and the material should be pounded into the mold. The bricks should be thoroughly dried so as to avoid fire cracks when placed in the kiln. Great care should be used when heating, especially during the first part of the burn, to prevent fire cracking; this applies also to the cooling. The bricks as they are removed from the kiln should be carefully inspected and all bricks showing molding defects, fire cracks and irregular shapes should be rejected.

The consumer should be allowed to inspect the bricks before they are loaded on the car and a place provided for storage of such brick as he may desire to test.

Testing of Refractory Brick

A number of timely recommendations for practice in testing refractory cement were presented at the Atlantic City meeting of the American Society for Testing Materials during June, 1917. These interesting papers and tentative tests are as follows:

Slag Test for Refractory Brick

Early in the study of the physical properties of refractory material in the iron and steel industry, the necessity for a slag test which would give information as to the relative resistance of refractory brick to various slags and fluxes became apparent. To be of use in specifications it was evident that such a test must be rapid, easily performed, and applicable to any kind of brick or slag, and should as far as possible approach conditions similar to those under which the brick is to be used.

As a basis for a test it was decided to place the brick in contact with a certain slag and apply heat until the slag was thoroughly melted. When cold the amount of penetration was observed. In the preliminary work the piling of the slag on the brick was tried, but the results were negative, as the slag ran off the brick as soon as melted, producing no marked penetration. Kaolin rings were tried in hope of confining the slag, but these failed to accomplish their purpose. Pockets were next cut in the brick by chipping. This proved to be successful in confining the slag, but the chipping was too slow and it was difficult to secure uniform cavities. Drilling by means of a press was next resorted to, and uniform pockets were drilled as near as the nature of brick material would permit.

A recommended procedure is as follows: The drill used should be 5/16 in. in diameter, the point should be tapered to include an angle of 150 deg., and the width of the bit should be such as to cut a hole 2½ in. in diameter. Drill a hole ½ in. deep on the sides. The cavity after drilling should be checked up by a standard template, and should conform to the same as nearly as the nature of the material permits. All loose material, dust and cuttings should be carefully removed from each cavity.

The bricks were then heated to testing temperature (1350 deg. C.) and a known quantity of slag was placed in the drilled cavities. After the bricks had become cold they were broken through the slag cavity and examined. Visual examination proved of small value, as results could not be accurately compared; hence it was found necessary to devise some means by which the amount of penetration could be measured. This was accomplished by sawing the brick so that one of the sawed faces accurately bisected the center of the original cavity, and the area of slag penetration thus exposed was then measured by means of a planimeter. The wheel used for sawing the brick is a carborundum wheel, 12 in. in diameter, ⅛ in. thick, 1½ in. diameter of center hole, grit 16, bond NCH, known as a vulcanite wheel.

To standardize the method it became necessary to determine whether the fineness of the slag, the time to which the slag was exposed to the brick, and the amount of slag used in the test had any effect upon the amount of penetration.

To determine the effect of fineness of the slag on the amount of penetration, blast-furnace and heating-furnace slags were selected as representative of the iron and steel industry. Each was ground and separated into two sizes, coarse and fine. The coarse material was that which passed a 40-mesh and remained on a 60-mesh sieve, while the fine was represented by that which passed through a 100-mesh sieve. The slag test was then run in the usual manner on standard hearth and bosh blast-furnace brick. The average results were as follows:

		Penetration, sq. in.
Blast-furnace slag	40 to 60-mesh	1.54
	100-mesh	1.67
Heating-furnace slag	40 to 60-mesh	1.77
	100-mesh	1.72

From the above results it seems that the degree of fineness of the slag does not affect the penetration.

To determine whether the time to which the slag was exposed to the brick, and also whether the amount of slag used in the test affected the penetration, a series of slag tests were run, in which the slag was exposed to the brick at testing temperature for two, four and six hours, with the quantity of slag varying from 35 to 140 g. The results of slag penetration are given in Table I.

From Table I it is shown that the amount of penetration is not increased by keeping the brick in contact with the slag for a longer period than two hours. Preliminary work had shown that one hour would in most cases give complete penetration, so that the adoption of two hours was considered sufficient.

[1]From a paper by C. E. Nesbitt and M. L. Bell and proposed tentative tests by the Committee on Refractories.

TABLE I PENETRATION OF SLAG FOR VARIOUS TIMES OF EXPOSURE AND AMOUNTS OF SLAG

Time of Exposure, Hours	PENETRATION FOR GRAMS OF SLAG USED, SQ. IN. 75	70	105	140
2	0.49	0.58		
2	0.51		0.79	
2	0.45			0.79
4	0.51	0.58		
4	0.43		0.78	
4	0.43			0.83
6	0.46	0.52		
6	0.44		0.70	
6	0.52			0.89
Average	0.45	0.56	0.76	0.84
Area exposed to slag action, sq. in.	5.94	7.07	8.57	9.44
Ratio of exposed area to standard cavity	1.00	1.34	1.44	1.59
Average slag penetration divided by ratio	0.45	0.42	0.53	0.53

It will also be noted that there are two variables, namely, the amount of slag used and the area exposed to slag action. To make the average results comparable these variables must be eliminated. This was accomplished by reducing the area exposed to slag action to a unit figure by dividing the area of the standard cavity (5.94 sq. in.) into each of the other areas (columns 3, 4 and 5 in Table I). The ratio figures thus obtained were divided into the average slag penetration and the results (slag penetration divided by ratio) made comparable. These figures prove that increasing the amount of slag does not affect the slag penetration, when reduced to a unit of area exposed to slag action. The variation in the results are within checking limits and the difference due to the variation in the bricks themselves. For routine work it is recommended that 35 grams of powdered slag (through 40-mesh) should be introduced into the drilled cavity after the brick has been heated to 1350 deg. C., held at that temperature for two hours, and cooled in the furnace.

The question of the advisability of performing a slag test in a drilled pocket as compared to immersing the brick in molten slag was next studied. Bricks from the same shipment were tested, one-half of them by the drilled-pocket method in the usual way, while the others were placed on edge in a refractory tray or shallow box,

TABLE II—RESULTS OF SLAG PENETRATION

Sample	Area No.	IMMERSION METHOD: Slag Penetration, Sq. In.	Slag Contact of Brick, Linear In.	Slag Penetration per Linear Inch of Contact	DRILLED-POCKET METHOD: Slag Penetration, Sq. In.	Slag Contact of Brick, Linear In.	Slag Penetration per Linear Inch of Contact

in which slag was placed to a depth of 1½ in. All were heated at a uniform rate to 1350 deg. C. and held for one hour. After cooling the bricks were cut at right angles to their length into two or three sections, the cuts being about 1 in. apart. The drilled-pocket samples were cut in the usual way, a second cut being

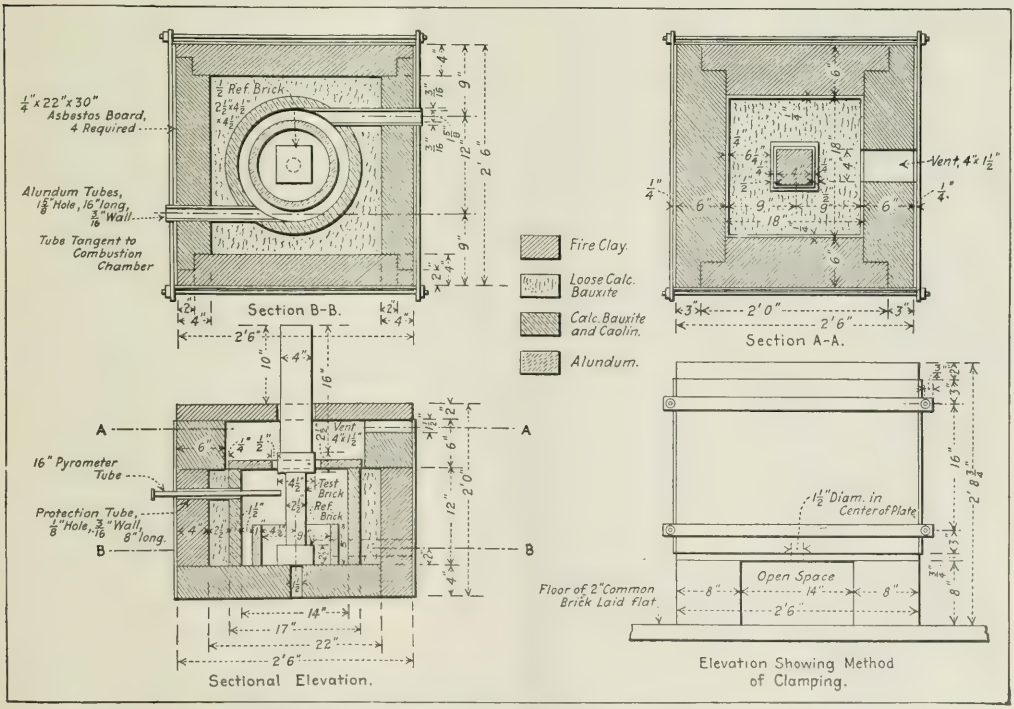

FIG. 1—APPARATUS FOR TESTING REFRACTORY MATERIALS UNDER LOAD AT HIGH TEMPERATURES

then made at right angles to the first. The areas of slag penetration thus exposed were measured with a planimeter; also, the linear inches of slag contact on the surface of the brick were measured. Heating furnace slag was used in this test. Table II gives the results of these tests.

From the results it is evident that greater uniformity of results is obtained by use of the drilled pocket than by immersion. The drilling of pockets to contain the slag is also preferable to the use of large trays to contain the slag, because of economy of space in the furnace.

The drilled-pocket method as at present adopted has several points which recommend it as a standard method. It is very flexible, as cavities, slags, temperature and the amount of slag can be easily changed to correspond to the service conditions under which the bricks are to be used. It is rapid, easily performed, and results are expressed by a definite numerical quantity.

When clay bricks for blast-furnace or similar uses are to be tested, blast-furnace and heating-furnace slags are used. Silica bricks for open-hearth use are tested with open-hearth and heating-furnace slags. The slags used in the development of this test were selected as representing the iron and steel industry and were of the following chemical composition:

	Blast-Furnace Slag	Heating-Furnace Slag	Open-Hearth Slag
Silica (SiO_2), per cent	38.0	35.0	18.4
Iron (Fe), per cent	1.5	44.0	14.5
Manganese (Mn), per cent	1.0	0.5	5.1
Alumina (Al_2O_3), per cent	14.5	0.0	3.8
Lime (CaO), per cent	42.0	1.5	44.1
Magnesia (MgO), per cent	2.0	0.5	6.3
Sulfur (S), per cent	1.0	....	0.4

Refractory Materials Under Load At High Temperatures[2]

The apparatus for testing refractory materials under load at high temperatures consists essentially of a furnace and loading device, constructed in accordance with Figs. 1 and 2.

The furnace is cylindrical in form, 14 in. in internal diameter.

The heating is done with gaseous or oil fuel and compressed air, using not less than two burners located tangentially and so arranged that no flame can impinge upon the test specimen. The burners must be such as will insure a uniform temperature in all parts of the furnace and be under complete control.

The details of the method of loading shown in Fig. 2 should be such as will insure accuracy in the applied load and freedom from eccentric loading, both in the original application and during the testing. It is advantageous to make the cross-beams as light as possible, so that the greater portion of the load may be concentrated in the weights.

The temperature may be measured either with a calibrated platinum-rhodium thermocouple, encased in a double protecting tube with the junction not more than 1 in. from the side or edge of the specimen and approximately opposite the center; or with some form of optical pyrometer which has been calibrated against a thermocouple in the furnace. If the thermocouple is used, the

[2]From tentative tests submitted by Committee on Refractories, A. V. Bleininger, Chairman.

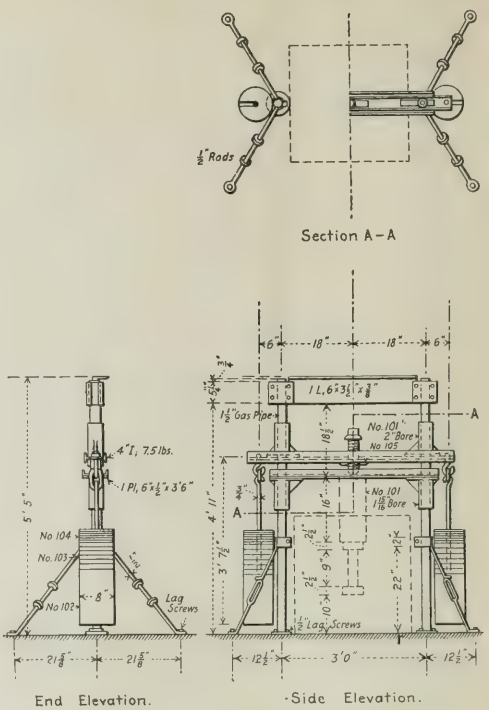

FIG. 2—METHOD OF LOADING

cold-end temperature should be kept constant in melted ice. A recording form of indicator is recommended where possible.

The test specimen consists of a standard 9-in. brick placed vertically on end. In the case of blocks or shapes cut a piece approximately 9 by 4½ by 2½ in., utilizing as far as possible existing plane surfaces. The ends of the specimen should be either ground so that they are parallel and perpendicular to the vertical axis, or if this is impossible should be bedded in a neutral cement, so that the specimen is perpendicular to the base of the furnace. The test specimen should be measured before testing to within ±0.02 in.

The test specimen occupies approximately the center of the furnace and rests on a block of some highly refractory material, having a minimum expansion or contraction. A silicon-carbide brick has been found satisfactory. At the top of the test specimen a block of similar highly refractory material is placed, extending through the furnace top to receive the load.

Table III—Temperatures for Heating at Various Periods

Material	Temperatures, in Deg. Cent., to be Maintained at the Time Intervals Specified					
	1 Hr.	2 Hr.	3 Hr.	4 Hr.	4½ Hr.	6 Hr. End of Test)
Silica material	200	500	900	1350	1500	1500
Fire clay (Heavy duty	500	900	1150	1300	1350	1350
Fire clay (Moderate duty	500	850	1100	1250	1300	1300
Fire clay (Light duty	500	750	950	1050	1100	1100

The method of heating should be in accordance with Table III, which gives the rate and time of heating suggested for different grades of material.

It is recommended that for general purposes a load of 25 lb. per square inch be used. The additional masses required to give the desired loading should be equally distributed on each side of the beam.

At the expiration of six hours the furnace is allowed to cool during a period not less than five hours, before removing the load and examining the test specimen. After the test specimen has cooled to the room temperature, it is remeasured as before, and the change in length recorded and reported as percentage of the original length.

It is recommended that a photograph be made of the specimen before and after testing as yielding valuable information at a minimum time and expense.

Crushing Test[3]

The apparatus may be any of the standard testing machines such as the Olsen, Riehlé, or others.

Operation of Test.—The brick to be tested is first carefully inspected and, if necessary, ground on a carborundum wheel so that both ends are parallel. The brick is then measured, placed in a cold furnace and heated at a uniform rate from atmospheric temperature to 1350 deg. C. (The heating as a convenience is done over night at a uniform rate, not exceeding 260 deg. C. per hour. The total time of heating should in no case be less than six hours.) The final temperature of 1350 deg. C. is maintained for not less than two hours. The brick is then quickly removed from the furnace and placed on end in position on the testing machine. To insure good bearing a thin piece of asbestos board is placed above and below the brick. The machine is started and operated until the brick is crushed. The crushing strength is recorded in pounds per square inch.

A Short History of the Detinning Industry*

The Goldschmidt Detinning Company is the largest concern of the kind in the United States and one of the largest in the world, detinning in excess of 100,000 tons of tin scrap per year and information on the company and its work should prove very interesting.

The tin plate, as practically everybody knows, is really a sheet iron plate coated with tin, the object being to combine the strength of the iron with the rust resisting quality of the tin. The art of covering sheet iron with a thin coating of tin dates back many generations. In fact, as early as the middle ages this art was practiced in the Bohemian Mountains. Later, during the early part of the 17th century the industry spread to Saxony, and about 100 years later it was introduced into Wales, where, in the course of time, it developed into the great tin plate industry which, since the beginning of the 19th century, has grown to be one of the most important branches of British commerce. The production of tin plate in England before the war was about 700,000 tons per year.

This Welsh tin plate industry absolutely controlled the market of the world up to about 1890, and it is rather interesting to know that about 70 per cent of the production was sold to the United States. Since the McKinley act of 1890, however, which placed a high protective tariff on tin plate, it became possible to establish the industry in this country, and it has developed so rapidly that it is larger by far to-day than is the old-established industry of Wales. Before the outbreak of the war over 1,000,000 tons of tin plate was produced per year in the United States, and at the present time the production is estimated at about 1,300,000 tons. It thus appears that tin plate is one of the great staple articles of the world.

Naturally, as the tin plate industry grew to large proportions, the question was raised as to what could be done with the clippings and other scrap which accrue and which accumulate in large quantities. In fact, this problem was considered as far back as the middle of the 19th century, and efforts were made to solve it. The problem was an important one, because unless the tin could be removed from the iron the scrap could not be remelted in puddling or melting furnaces.

The problem at first did not appear to be very difficult, and it was bound to appeal to the inventor, as the can factories were glad to give their tin scrap away for the asking, and even went so far as to pay cartage simply to get rid of it. However promising the problem appeared, and although many ways seemed to be open for the engineer and chemist, it required many decades of study and experimentation before a feasible method was developed which yielded sufficiently valuable results to make it a paying proposition.

It is not possible here to enumerate all the various suggestions which have been offered to solve the problem, the literature in the field is very extensive and hundrds of patents have been taken out in the United States and abroad. Of these but a very few have really been used.

All the processes which have been actually operated may be divided into three general classes, i.e. the mechanical process, the chemical process and the electro-chemical process.

In the mechanical process the effort was made to separate the tin from the iron by means of heat, and more recently by refrigeration. The methods were impractical, however, for one reason or another, but mainly because it was not possible to obtain a thorough separation of the tin from the iron.

Most of the chemical and electro-chemical processes were also failures, either because the acids used attacked the iron as well as the tin or because they would not dissolve the tin sufficiently and left considerable adhering to the iron. It was also found in many cases that the chemicals used were too expensive to make the process an economical one. Three processes, however, have operated successfully and have been in more or less competition with each other for the last forty years, during which time one or another has alternately obtained preponderance due to refinements in that process over the others. These three processes are the electrolytic alkali process, the chlorine process, and the alkali chemical process.

[3] From an appendix to a paper on Improvements in the Manufacture of Silica Brick, by C. E. Nesbitt and M. L. Bell. Other tests for refractory fire-brick have been developed by the same authors, such as impact, spalling, expansion, size and abrasion, which have already been published in Metallurgical and Chemical Engineering, Vol. XV, page 208 (August 15, 1916).

*From *Reactions*, second quarter, 1917.

As far back as the year 1876, Keith* recommended the electrolysis of tin scrap in an alkali solution, while in 1882 Th. Goldschmidt in Germay conducted experiments with a warm solution of caustic soda, using the tin plate as the anode and the iron plate as the cathode. This exceedingly simple idea has been the basis for the further development of the industry, but however simple such a laboratory experiment may be the operation on a commercial scale often results in a great many difficulties, both electrochemical and mechanical, which have to be overcome. These were undoubtedly met with and probably solved in some manner.

One trouble with the process was the fact that the electrolyte had to be watched constantly, and great care had to be exercised in order to thoroughly separate the tin from the iron. The tin is recovered at the cathode in the form of a spongy or finely granulated precipitate, which may be easily removed and melted. The process, therefore, in spite of the care required offers a considerable advantage as it obtains a serviceable iron in one single operation, which may be compressed into solid billets and for which a market can be readily found. It also furnishes a tin sludge which may be easily melted into pig tin. This fact and the apparent, though not real, simplicity of the process caused it to come into quite general use in a comparatively short time, so that up to about 1907 it practically dominated the entire field.

We now come to the chlorine process, which was taken up first in England by Higgins[1] in 1854, and later by Parmalee[2], Seely[3] and Panton[4] in this country. At the time the fact was recognized that it was very essential to use only absolutely dry chlorine gas, which will combine with tin under the development of considerable heat to form anhydrous tetrachloride of tin. This is a heavy liquid which fumes strongly in air and has been known to chemists for about 300 years. In fact, as early as 1605 the chemist Libavius described this product, and ever since that time it has been known under the name of Liquid Fumans Libavii.

When dry chlorine is brought in contact with tin clippings, the chlorine and tin will combine and the anhydrous tetrachloride of tin which is formed will drip off. As chlorine at low temperature does not attack iron the process apparently is very simple. Simple as it may seem, however, it required a number of years to develop the process in such a way that it could be used commercially.

A chlorine detinning plant was established in New York City in 1873, operating according to the Seely patent, but the concern failed when the financial panic of that year brought ruin to so many concerns. Further progress was made in chlorine detinning about 1885, when Lambotte in Brussells started to operate on a large scale with a shaft furnace which was filled with tin scrap from the top, while chlorine gas strongly diluted with air, was introduced at the bottom. This chlorine was combined with the tin from the scrap while the air would carry away the tetrachloride of tin to condensers, where it would be condensed as a watery solution of tetrachloride of tin. The detinned clippings were then removed from the bottom of the furnace and compressed into billets. This process is rather simple in its operation, but the control of the chlorine gas and the tin chloride fumes was difficult and the workmen attending the furnace were greatly annoyed. Furthermore, the detinned clippings could not be entirely detinned and were covered to a certain extent with tetrachloride of tin.

It was not until 1907 that the chlorine detinning process gained real importance as, in that year, Th. Goldschmidt, the pioneers in the detinning industry, abandoned the electrolytic method entirely in favor of the chlorine process which they had developed. Since then it has grown very rapidly, and to-day there are larger quantities of tin scrap and old tin cans detinned with the chlorine process than by all the other processes combined.

Some of the basic conditions of chlorine detinning had been correctly observed by the early experimenters, one of which, and most important, being that all humidity must be excluded in order to avoid a destroying effect on the iron. This is as important to-day as it was then, and it has also been found that the material must be free from all organic substances, such as paper, straw, varnish, etc. The dry tin scrap, therefore, is put into large cylindrical containers either in more or less loose form, or compressed into billets. These containers, after being filled, are closed tight. Dry chlorine is then introduced, and as considerable heat is formed during the combination of tin and chlorine it was early recognized that the heat should not be allowed to raise the temperature of the detinning too high. Means had to be found, therefore, to cool the apparatus and carry off the heat.

In order to achieve a complete detinning the process is carried on under varying pressure so that the chlorine will be forced into every part of the mass of tinned scrap.

After all the tin has combined with the chlorine the liquid tin chloride is removed and the apparatus emptied. The detinned scrap is washed and is then ready to be shipped to the steel mills.

This process possesses considerable advantages over the electrolytic process, as it can be carried on in larger units and the labor charges are therefore materially reduced. The detinning is more thorough and no tin is lost, as in the electrolytic process. The tin is recovered in the form of tetrachloride of tin, which is a valuable chemical product extensively used in the silk dyeing industry. The result is that this process has grown more and more at the expense of the electrolytic and other processes.

We now come to another process which has been touched on previously, namely, detinning by means of alkalies, either alone or in combination with oxidizers. This method was practised at an early stage of the industry, but it did not always remove a sufficient amount of the tin, with the result that a considerable part was left on the iron. It is only within recent years that this process, using alkali and saltpeter, has been developed to a point where the results compare in every respect with the product of the chlorine process.

In this process the scrap is cleaned very carefully and is then placed in a well-heated solution containing

*U. S. Patent 176,658.
[1]English Patent U.766, 1854.
[2]U. S. Patent 102,148.
[3]U. S. Patent 127,375.
[4]U. S. Patent 135,578.

a considerable excess of free alkali and saltpeter or other oxidizer. The mass is then kept at a boiling temperature for several hours during which the tin reacts to form stannate of soda which accumulates in the form of crystals. These crystals ars drawn off and subjected to centrifugal action while the remaining mother lye is diluted with the necessary caustic soda and saltpeter to enable it to be used again in the same way as the original solution.

The stannate of soda is subjected to further treatment by dissolving in water and precipitating oxide of tin by means of bicarbonate of sodium. It should be borne in mind that the alkali used in this process is always recovered and used over and over so that only a very small loss results. The saltpeter is also recovered at the end of the operation with the exception of the amount required for the oxidation of the tin.

The tin oxide obtained in this process is used extensively as a coloring matter in the enamel industry or is smelted in reverberatory furnaces to form pig tin of very high quality.

The Goldschmidt Detinning Company uses this process as well as the chlorine process in its various plants and its output therefore in addition to detinned scrap comprises large amounts of tetrachloride of tin and pig tin of a purity which in every respect is the equal of Straits tin. The company recovers every year the equivalent of almost 2000 gross tons of metallic tin.

Synopsis of Recent Metallurgical and Chemical Literature

Radium

Radium Luminous Compounds.—The discussion of a paper on investigations of radium luminous compounds read at a meeting of the Physical Society of London by C. C. PATERSON, J. W. T. WALSH and W. F. HIGGINS is given in *The Chemical Trade Journal* and *Chemical Engineer* for June 16, 1917.

The paper contained the results of measurements made on various samples of radium luminous compounds during the last two years. Determinations of the brightness of the compound in powder form and when made up into paint, and also after the application of the paint to instrument dials, were carried out, and curves were given showing the rates of decay of luminosity. The radium contents of the compounds were determined by comparison of their γ-ray activities with that of a preparation of pure radium bromide, which is periodically compared with the British radium standard. The various precautions which have to be observed and the corrections which have to be applied in making the various determinations were explained, and the considerations which should govern the proportion of radium employed for practical purposes were discussed.

In the discussion which followed Mr. F. H. Glew said the difference between some of Marsden's results and those of Dewar and Crookes had been attributed to some difference in the zinc sulphide employed; he could state that the sulphide supplied to the National Physical Laboratory was of different origin from either of these. Before the war we were almost entirely dependent on foreign sources for the supply of these materials, but we are now quite self-supporting. In Marsden's work the inside of the tube was completely coated with sulphide, so that the effects were observed by light transmitted through the material. It was better to paint only one-half of the tube, so that the inner surface, which was exposed to the bombardment, could be directly observed. It was singular that specimens prepared by the dry and wet methods should be so similar in their properties after only four days, for in the dry method the emanation and all its products are retained.

Dr. H. S. Allen asked if the zinc sulphide employed was wholly crystalline or partially amorphous. An investigation of its physical condition would be useful.

Mr. J. S. Dow said the figures for the absolute brightness were what he would have expected. He was doubtful of the possibility of expressing the brightness accurately; consistent results could be obtained, but they did not represent exactly what the eye saw. For instance, zinc sulphide and cadmium sulphide may be equally bright a few inches away, but the former will look much brighter at a distance. Had the authors noticed any change of color as the compound got older? He thought it got greener as it aged. The initial rise in the luminosity curves for the weaker materials seemed greater than could be explained by the lower rate of decay.

Dr. Levy said he had found the luminosity of different samples of zinc sulphide to vary perceptibly in tint when stimulated by daylight, but had not noticed this with α-ray stimulation. In his experience, if a sample of sulphide gave good results when stimulated by daylight, it would also be good when stimulated by radium. The reverse did not hold, however, as a specimen might be poor with daylight, but good with radium excitation.

Mr. Walsh, in reply, said that to detect change of color with age would have been difficult in their experiments, because of the continuous decrease in luminosity. They had detected differences in color in samples sent by different makers, but were unaware whether these were from the same source, or made in the same way. They had no data on the relation between daylight and radium excitation, and Dr. Levy's remarks were of great interest.

Iron and Steel

Sulphur as a Component of Furnace Slag.—A very interesting article on the mentioned subject was published in *Blast Furnace and Steel Plant* of July, 1917, by WALLACE G. IMHOFF. As is well known, sulphur occurs in slags in three forms, first, as combined sulphur in the form of calcium sulphide, second, free sulphur held in solution in the slag, and third, sublimated sulphur, the result of an excess of sulphur in the burden.

The sulphur in a furnace charge is mainly in the ore and coke while only small amounts are found in the flux. With lake ores the sulphur going into the furnace will fall within the limit of 1½ per cent, while furnaces, and especially merchant furnaces, with high sulphur coke and pyrites cinders in the burden will run as high as 6 and even 8 per cent in sulphur.

The author cites two examples, figuring in one case the amount of lime required to slag a high percentage of sulphur and in the other where the percentage of sulphur is lower. Careful regulation of the lime is essential since most of this sulphur is eliminated in the slag, although some is carried out by the furnace gases.

In the second example the writer shows the effect of excess lime on the furnace operation. The excess limestone lowers the temperature of the furnace, fluxes the silica, and absorbs the silicon normally entering the iron. Thus as conditions grow worse, and the furnace gets cooler, the silicon content of the iron is lowered, and the sulphur in the iron increases. This accounts for irons extremely low in silicon and high in sulphur resulting when a furnace cools off from being "overlimed." Very often in practice more stone is added as the sulphur in the iron rises, only making the conditions more extreme and resulting in the formation of a very infusible slag: a slag which will at times fill the bottom of the furnace, freezing in the bosh and often terminating in a complete shutdown.

The largest amounts of calcium sulphide are found in foundry-iron slags, which as a rule are high in alumina. The author states that the alumina fluxes the bulk of the silica, while the lime fluxes the sulphur and only a small proportion of the silica. These foundry-iron slags under normal conditions usually show a blue color due to the aluminium silicate. As soon as the furnace gets cool the slag becomes glassy due to silica going into the slag as such. If the furnace is permitted to get still colder, lime silicates will be formed, when the slag is creamy white in color. Then the iron will show an increase in sulphur content, as is shown in Fig. 1, below. A hot furnace working a slag heavily oversatu-

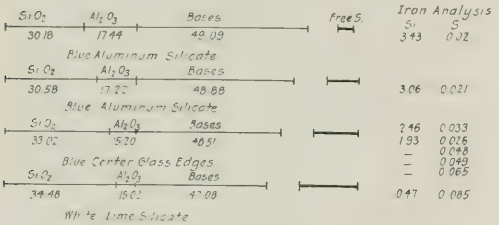

FIG. 1—RELATION OF SLAG COMPOSITION TO SULPHUR IN IRON

rated with calcium sulphide and a high-sulphur burden produces a very heavy, smoky gas, giving rise to a white deposit near the tuyeres. Some of this deposit was analyzed and found to contain 4.20 per cent CaO and 10.73 per cent sulphur. Analyses of slags drawn from such furnaces seem to indicate that these oversaturated slags give rise to such fogs on reaching the atmosphere.

Indirectly calcium sulphide effects the condition of the carbon in the pig iron. When the furnace is working with very heavy lime, a hot bottom and high combined sulphur, the cast house is generally filled with graphitic carbon. This indicates that the formation of calcium sulphide in the slag has a tendency to promote the formation of graphite in the pig iron. The large amount of graphitic carbon in the iron makes the product extremely dry and mushy. Other effects of a hot furnace and heavy lime are: slow working and low fusion zone. The latter is due to the formation of large amounts of combined sulphur.

The author then gives a discussion of basic slags and slags obtained with foundry iron. He illustrates the heating value of the gases obtained in both instances and explains why basic-iron slags generally show less combined sulphur than do the foundry-iron slags. He then states that it is very seldom that all the sulphur present in slags is in the combined form. Some always occurs in the free state and it may be observed in any gas cavities. The foundry-iron slags very high in aluminium which are solid, dry, dense, and grainy are those carrying the largest percentage of combined sulphur. The average basic slag contains less than 1.75 per cent sulphur and the average foundry-iron slag varies between 1.60 per cent and 2.50 per cent of combined sulphur. The combined sulphur depends mainly on the total sulphur entering the furnace, the position of the fusion zone, the hearth temperature, and the slag volume.

The relation of the sulphur in the slag to the slag volume is as follows: Assuming the total sulphur going into the furnace to be practically constant and all other furnace conditions remaining the same, the sulphur content of the slag will be inversely proportional to the slag volume.

Quantitative Determination of Air Dust.—In the *Heating and Ventilating Magazine* for June, 1917, E. Vernon Hill of the Department of Public Health, Chicago, Ill., gives a review of the various methods devised for the determination of the number of dust particles in air, discusses the difficulties encountered and describes types of dust counters developed by him. The latest of these consists essentially of an exhaust pump of known capacity for handling the air and a small capsule or shell affixed to the inlet of the pump, carrying a cover glass, coated with adhesive material for catching and retaining the dust. The author's first experiments in this line were made by drawing a quantity of air into a syringe and forcing it out against a slide covered with adhesive material and counting the number of particles with a microscope. In using this method he found a serious source of error in the retention of dust particles in the barrel of the pump. A device was, therefore, arranged to carry the cover slip on the interior of the pump directly beneath the intake nozzle. With this arrangement the dust was projected against the adhesive material before coming in contact with the interior of the pump.

This was the first instrument developed in the long series of tests with which a consistent and practical determination could be made. In developing the idea just described the next step was to find some means of calibrating the instrument. It was evident that all of the dust projected against the adhesive plate was not retained, some must of necessity escape. A number of capsules were therefore constructed as a separate part of the instrument and designed them in such a way that one could be superimposed upon the other and the air sample drawn through them in series. By experiment it was found that with six such capsules under ordinary or moderately extreme conditions of air dustiness no dust was found in the last capsule. Counts were then made of the samples in the consecutive capsules and a percentage determination arrived at for the amount retained by the first capsule. In routine tests with the instrument, therefore, it is only necessary to use one capsule and correct the result by the factor given for the nature of the work in hand. This for ordinary tests is 62 per cent. The author states that it is not only possible to accurately deter-

mine the number of dust particles, but a study of the kind and character of the dust under observation is often instructive and valuable. This feature greatly enhances the value of the method and makes the work extremely interesting. Counted by this method the particles in clean, outdoor air average from 500 to 1500 per cubic feet. In a mechanically-ventilated school room, without air washers or other air cleaning device, from 10,000 to 30,000. It is also a practical method for testing the efficiency of air washers. For this purpose a "Y" connection is used on the pump and two capsules used simultaneously, one at the proximal and one at the distal end of the washer, connections being made to the pump with rubber tubing.

Some experimental results obtained by two students of the Armour Institute of Technology in work of this kind are of interest. Messrs. Otto Armpach and E. W. Haines made the tests in preparing their graduation theses. The tests were conducted during March and April of the present year on a Webster air washer furnished by Wm. G. Braemer, then manager of the air conditioning department of Warren, Webster & Co., in the experimental laboratory of the Ventilation Division of the Chicago Health Department.

QUANTITATIVE DETERMINATIONS OF VARIOUS KINDS OF DUST REMOVED BY AN AIR WASHER

	Medium	Heavy
Lamp black	89.4	91.2
Rubber dust	90	92.3
Street dust	96.2	98.2
Wood dust	96.5	99.2
Grain dust	98.5	99.2
Rattler dust	99.5	99.7

The "medium" and "heavy" at the head of the two columns refer to the amount of dust that was liberated in vicinity of the intake of the washer. These are the only tests of this character that the author knows of in the literature of air conditioning work.

A statement previously advanced by the author is brought out clearly in these tests, viz., that the per cent of efficiency in dust removal of an air washer increases directly with the amount of dust entering the washer. In every instance these tests show the per cent of removal higher when the quantity is "heavy." The author emphasizes the statement: that with any method of dust determination the results are relative only, they cannot be absolute. This is due to the fact that a considerable number of the minute dust particles that are always present are not caught in the liquid when dust is collected by bubbling through water but pass through with the bubbles, the amount retained increasing as the size of the bubbles and velocity of air passing through the liquid decreases. He has repeatedly drawn room air through a Drechsel bottle with a 3-in. water seal and counted as high as 7000 small particles per cubic foot that were not retained in the water. Air passed through four wash bottles in series still gives a light beam with the diffractoscope. On the other hand, while much of the dust that passes through the wash bottle can be collected and counted with this latest dust counter, even with this instrument some particles are so small that the magnification used does not reveal their presence.

Recent Metallurgical and Chemical Patents

Iron and Steel

High-Speed Steel.—An alloy high-speed tool steel of the tungsten-chromium-vanadium type is patented by James H. Parker of Reading, Pa., and B. H. De Long of Springmont, Pa. (assigned to Carpenter Steel Company of Reading, Pa.). The alloy has a high proportion of cobalt and has approximately the following composition:

	Per Cent
Carbon	0.35
Vanadium	2.00
Chromium	3.50
Tungsten	12.00
Cobalt	30.00
Iron	52.15
	100.00

The proportions of iron and cobalt correspond with the eutectic proportions. It is claimed that the alloy will give maximum service with increase of possible speed and cut. (1,233,118, July 10, 1917.)

High Speed Tool Steel Alloy.—A patent issued to Radclyffe Furness of Jenkintown, Pa. (assignor to the Midvale Steel Company), states that if a certain amount of both cobalt and tungsten be added to an ordinary high-speed tool steel, containing tungsten, chromium and vanadium, a substantial increase in cutting efficiency is attained. The amount of uranium is so small that it cannot be said to replace the known high-speed tool steel additions, its presence even in apparently negligible proportion improving the efficiency of the tools.

	Preferred Analysis, Per Cent	Limiting Proportions, Per Cent
Cobalt	4.5	3.0 to 7.0
Uranium	0.7	0.1 to 2.0
Tungsten	13.5	12.0 to 20.0
Chromium	3.5	2.0 to 6.0
Vanadium	1.5	0.5 to 2.0
Carbon	0.7	0.5 to 0.9

(1,233,862, July 17, 1917.)

Deoxidizer for Steel Baths.—J. I. Bronn of Rombach, Germany (assignor one-half to Rombacher Hüttenwerke), patents a substitute for ferromanganese or other expensive de-oxidizers to produce a workable steel. The oxygen containing iron baths obtained at the end of the Bessemer or open-hearth processes are deoxidized with a molten pig iron high in phosphorus. If a calculated amount of phorphorus is used to react with the oxygen in the bath, no substantial impurification results. Under certain circumstances it may be advisable to charge an excess of phosphorus, which can easily be removed by a short refining without appreciably reoxidizing the metal. The deoxidizing effect of the addition of Thomas pig iron to the converter charge appears from the following comparative data relating to working with Thomas pig iron containing 0.45 per cent silicon, 1.20 per cent manganese, 1.85 per cent phosphorus and 3.5 per cent carbon.

	Mn, Per Cent	P, Per Cent	C, Per Cent
Iron bath at end of blow	0.19	0.045	0.05
After addition of Thomas pig-iron	0.25	0.085	0.07

It is advisable to add the molten phosphorus containing pig iron in the converter after skimming in order to

improve the intermixing. In connection with the open-hearth furnace the bath is refined as usual and the iron rich in phosphorus added in the molten condition when the furnace charge is nearly finished. Care is to be taken that the slag layer on the iron bath is not very high in phosphorus and that it is in as thin liquid condition as possible. The following comparative data show the effect of the addition of Thomas pig iron:

	Mn. Per Cent	P. Per Cent	C. Per Cent
The furnace charge (33 tons) after refining contained	0.26	0.030	0.10
The Thomas pig iron addition (1500 kg.) contained	1.75	2.78	3.5
The deoxidized bath contained	0.43	0.062	0.15

The bath shows an increase in manganese over the amount of manganese contained in the pig iron addition, namely:

The bath contained	$330 \times 0.26 = 85.8$ kg.
And the addition	$15 \times 1.75 = 26.1$ kg.
This makes together	111.9 kg.

whereas the bath contained as above stated 0.43 per cent manganese or 148 kg., so that an increase of 36.1 kg. manganese has taken place. The phosphorus on the contrary shows a considerable decrease, namely:

The charge contained	$330 \times 0.03 = 9.9$ kg.
The addition	$15 \times 2.78 = 41.8$ kg.
This makes together	51.7 kg.

whereas the bath contained $345 \times 0.062 = 21.3$ kg., so that a decrease in phosphorus of 30.4 kg. has taken place which have been used for deoxidizing purposes. These data relate to the pig and ore process. Similar results are obtained in connection with the pig and scrap process. If compared with the usual deoxidation process with ferromanganese alone the deoxidation with pig iron (Thomas pig iron) rich in phosphorus results in saving 2 kg. metallic manganese or 4 kg. ferromanganese with 50 per cent of manganese for each ton of steel. (1,233,970, July 17, 1917.)

Zinc Distillation

Condenser to Produce Pure Zinc.—A patent issued to A. J. F. de Bavay, Kew, Victoria, Australia, covers a proposed construction of condenser where pure zinc may be attained by the separation of other volatile metals by passing the complex distillate seriatum through a series of differentially heated liquid condensates. In practice, the condenser B is just charged with the proper amount of molten zinc sealing the downwardly projecting baffles B^2, and a reducing gas containing zinc vapor drawn from the furnace A by the suction of the fan F. Three compartments are shown, separated by the upwardly projecting baffles B^1. These baffles are formed with a groove B^2, with the near side slightly lower than the other, the groove being connected to a pipe B^4 (Fig. 1) dipping into a pot D of molten zinc of sufficient head required by the fan suction. In this way a constant level of the bath is maintained, zinc being ladled from D from time to time as it accumulates. Each compartment has also a drain B^6. The temperature in the various chambers is above the melting point of zinc, and is differentially decreased toward the fan. The metallic vapor is drawn through the molten zinc, passing from one compartment to the other, being practically freed from fume at the exit. The impurity lead is mostly collected in the first compartment, while the molten zinc in the succeeding chambers is differentially free from other impurities, and cadmium-zinc may be collected in the last condenser. (1,233,652, July 17, 1917.)

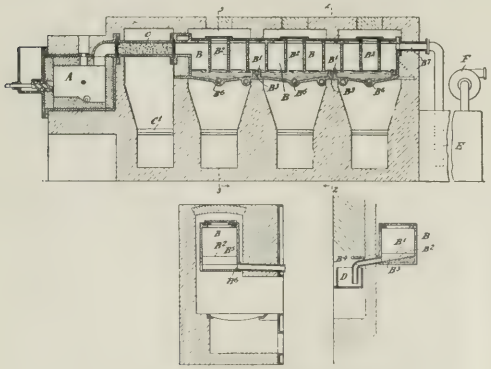

FIG. 1—ZINC DISTILLATION FURNACE

Glass

Quartz-Glass-Making Machine.—A machine for making tubes, flasks, etc., of quartz glass is patented by Armin Frost of New York, N. Y. It consists of a cylindrical melting chamber having a double wall, the space between the walls being filled with the same material that the vessels are to be made from, in order to prevent radiation and loss of heat. The melting chamber is filled with the charge and heated by a graphite rod passing through the center of the chamber and connected at each end with a source of current. When the annular core surrounding the rod is melted, the current is turned off and the furnace withdrawn from the upper electrode by lowering the elevator upon which the melting chamber rests.

In the opening at the top of the tube formed by the core, after the graphite rod has been withdrawn, is inserted a blowpipe, the tube being tightly closed upon it, so that no air can escape and the desired thickness of the tube attained by the proper lowering of the elevator, taken in connection with the admission of compressed air, causing the tube to be formed uniformly thick and straight.

The molten glass still remaining on the electrode in the melting chamber is let down by the elevator and inclosed in molds of the proper shape, the glass being forced outwardly by the compressed air entering through the pipe. (1,232,785, July 10, 1917.)

Thermostat.—The accompanying drawing represents a vertical central section through the apparatus, some of the parts being shown in side elevation, invented by Niels Bendixen of Copenhagen, Denmark, which operates as follows: By a swift rise of the temperature the fluid in the receptacle 4 is vaporized, whereby the pressure of the vapor acts upon the diaphragm 6, the pin 8, and one end of the spring 12, so that the latter moves upward. The contact 14 thereby will come in touch with contact 15 and close an electrical circuit through the wire 22, the stud 2, the spring 12, the contacts 14 and 15, the spring 13, the stud 3 and the wire 23, thereby operating the alarm bell or the like, which is inserted in the circuit. The fluid in the receptacle 5 is only slightly influenced by the sudden rise of the tem-

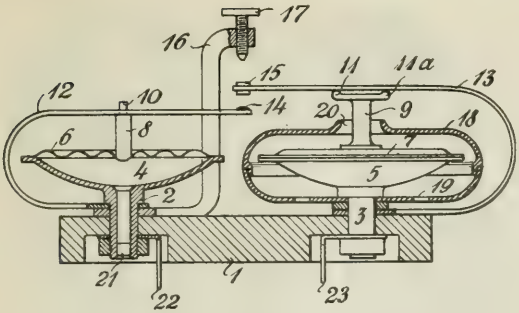

FIG. 2—CROSS-SECTION OF THERMOSTAT

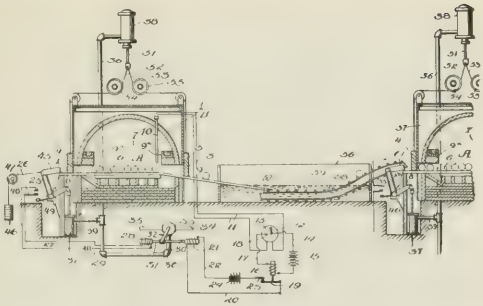

FIG. 3—AUTOMATIC HEAT-TREATING FURNACE

perature, because this receptacle is protected by the case 18, so that the spring 13 and the contact 15 remain in almost unaltered position. By a slow rise of the temperature the receptacle 5 will be heated almost as swiftly as the receptacle 4, the air circulating through the openings 19 and 20. The contacts 14 and 15 will therefore both move upward, but without touching each other. When the rise of the temperature has reached a certain height, the contact 15 will touch the screw 17, and a circuit is then closed through the wire 22, the stud 2, the rod 16, the screw 17, the contact 15, the spring 13, the stud 3 and the wire 23. Of considerable importance to the invention is the particular shape of the pin 9. When the spring 13 is in its central position—as shown in the drawing—it is touched by both bifurcations 11 and 11^a. If the temperature rises, so that the spring 13 is moved upward, it is only touched by the point 11^a, and the speed of the contact 15 is thereby increased. If the temperature is lowered, so that the spring 13 moves downward, the arm of the lever is altered, so that the speed of the contact 15 decreases. This arrangement is very advantageous for preventing errors which may arise on account of the diaphragms not being manufactured quite similarly and therefore not moving with the same speed. (1,233,746, July 17, 1917.)

Heat Treating

Automatic Heat-Treating Furnace.—The continuous pusher-type furnaces mentioned in our issue of July 15, 1917 (Vol. XVII, page 91), have been patented by T. F. Baily and F. T. Cope, assignors to the Electric Furnace Company. The operation is as follows: The billets A are placed one at a time upon the extension 8 of the billet support. As the temperature in the rear end of the heating chamber 7 adjacent the thermocouple 10 reaches the proper degree, the thermocouple moves the arm 13 into engagement with the contact plate 18 closing the relay 16, thus closing the circuit through the solenoid 21 (shown in Fig. 3). The arm 32 is drawn toward said solenoid, connecting the pipe 36 with the water supply. The water operates the pistons in the cylinders 37 and 38, opening the doors of the furnace and pushing the billet which has been placed upon the outside of the door into the heating chamber against the other billets, moving all of them forward. The billet adjacent the door 5, being heated to the proper degree, is pushed from the furnace down the inclined chute 9 into the quenching trough, where it is properly quenched and picked up by the continuously operating endless carrier 58, which carries it upwardly and deposits it upon the billet support of the annealing furnace 57, from where the billet is carried through the annealing furnace in the same manner in which it has been moved through the hardening furnace, the mechanism connected with the annealing furnace operating in the same manner. As the finger 49 comes into contact with the pivoted arm 26, it moves the arm into contact with the contact plate 25, closing the circuit through the solenoid 28. The temperature within the heating chamber of the furnace 1 will by this time have been lowered sufficiently to cause the arm 13 of the pyrometer to move out of contact with the contact point 18, thus breaking the circuit to the relay 16 and to the solenoid 21. The armature of the solenoid 28 will then be operated, moving the arm 32 back into the original position connecting the pipe 36 with the discharge. The weight of the doors will then cause them to close and the counterweight 46 will bring the pusher back to the normal position. (1,234,257, July 24, 1917.)

Binding Material for Briquettes.—A binding material and the method of preparation is invented by Walther Mathesius, Berlin-Nikolassee, Germany. It is based upon the fact that finely pulverized iron oxide and hydroxide will enter into the molecule of free lime or alumino silicates containing a high percentage of lime, forming ferroalumina silicates of lime at temperatures below the temperature of sintering, after which heating the material is still easy to pulverize. The resulting substance on being mixed with further iron ore or iron oxide bearing material, moistened or molded, will agglomerate most perfectly and furnish excellent stable briquettes. (1,233,384, July 17, 1917.)

Conditions in the Abrasive Industry

Col. P. R. Hawkins, of the Norton Company, Worcester, Mass., has supplied the following statement regarding conditions in the abrasive industry to Maurice R. Scharff, executive secretary in Washington of the Technology Clubs Associated.

"We wish to bring to your attention the probable shortage in abrasives, grinding wheels and grinding machinery necessary to manufacture the large quantity of munitions and other supplies required by the United States Government.

"Imports of emery have practically ceased during recent years so that the grinding wheel industry is dependent upon artificial abrasives. These are manufactured from bauxite and carbide of silicon. The leading

and perhaps best known abrasive manufactured from bauxite is Alundum, and Crystolon and Carborundum are examples of those made of carbide of silicon.

"There is a great shortage of cars necessary for the shipment of bauxite from the mines in Arkansas to the places where abrasives are manufactured; the power supply at Niagara Falls, where the important abrasive plants are situated, is likely to be inadequate; we cannot obtain sufficient alumina to make the necessary amount of white alundum, a special abrasive used principally for munitions grinding wheels, and if the draft should to-day take all the men registered in our works we would lose fully 45 per cent of our organization. These are some of the problems which confront abrasive manufacturers at the present time. Norton Company, the largest manufacturer of grinding wheels in this country, is doing what it can to meet these conditions, but the situation should be thoroughly understood by those who are working in the interests of the Government.

"We have the example of England which did not appreciate the situation with regard to grinding wheels and found itself in a very serious position on account of the lack of wheels for grinding shells, gun barrels and other necessary munitions work. The Munitions Board of Great Britain finally sent representatives to this country and we, among others, were very urgently appealed to to help relieve the situation, which we did to the greatest possible extent. We expect a similar condition to occur in this country and everything possible should be done to anticipate the shortage."

Washing Filtercloths

An interesting machine for washing filter cloths is made by the Clenzall Machines Company of America, St. Louis, Mo., under the name of the "Clenzall" washing machine. An illustration of this machine is shown in Fig. 1.

The apparatus consists in its essential parts of an outer case and an inner drum. The inner drum is

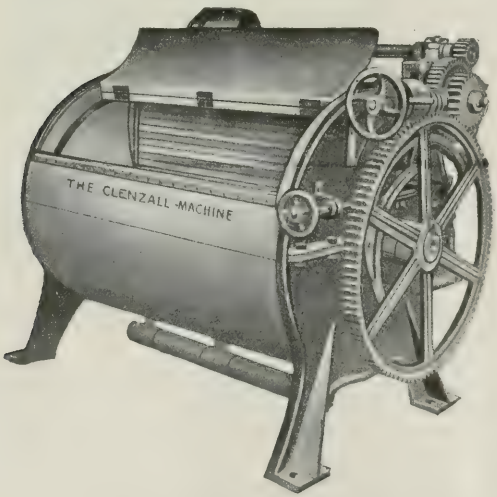

FIG. 1—GENERAL VIEW OF MACHINE FOR WASHING FILTER CLOTHS

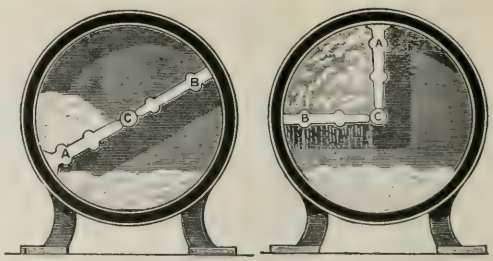

FIGS. 2 AND 3—INTERIOR VIEWS OF MACHINE

divided into two compartments by a diaphragm, the upper half of which *A* is mounted on shaft *C* and is held in position by springs fixed to the outer case, while the lower half *B* is fixed to and moves with the inner drum.

The machine is loaded on both sides of the diaphragm as shown in Fig. 2 and being set in motion, the cloths on one side are lifted out of the washing liquor while those on the other side spread out in and absorb the liquor, as shown. During this part of the operation the diaphragm is fixed in a straight line, thus dividing the drum into two equal compartments.

When in action, the inner drum never makes a complete revolution, but only moves through three-quarters of a circle. This insures the rubbing action necessary for a superficial washing and prepares the cloths for the squeezing action which takes place later.

After this rubbing action has gone on for a few minutes, the clutch is altered so that the diaphragm *B* moves with the inner drum while the diaphragm *A* remains fixed to the center shaft *C*. T he squeezing action now begins.

The cloths are then carried upward on *B* until they come in contact with *A* and are squeezed. The drum then reverses automatically and the cloths are rubbed.

The machine is supplied complete with all gear wheels, pulleys, automatic reversing gear, water and steam inlets and outlets, etc. The outer case is made of galvanized steel plate and the inner drum of brass and fitted with the patent movable diaphragms.

Taking an ordinary example, the standard size of machine will deal at each operation with about fifty to sixty cloths each measuring about 27 x 54 in. (that is to say, cloths that would be used on a press with plates 25 in. square). In the majority of cases only hot water and steam will be necessary, when the washing time would be about fifteen to twenty minutes, but with oils, varnishes and similar materials the time would be somewhat longer, depending upon the nature of the filtrate, and for these it is necessary to use special solvents.

Although this machine is primarily intended for washing filtercloths, it is being used with entirely satisfactory results for washing overalls, sponge cloths, cotton wipers, bags, etc.

New Types of Industrial Cars

The many new processes developed since American industries were thrown on their own resources in the matter of chemicals have necessitated much new and special equipment.

The illustration, Fig. 1, shows a new type of side dump car, built for the Contact Process Company by the Orenstein-Arthur Koppel Company of Koppel, Pa.

The material to be transported comes from the furnaces in a liquid form at a comparatively high temperature and solidifies on cooling. These cars were specially designed in order to provide an efficient means for handling and transporting this material, which flows directly from the furnaces into the cars.

FIG. 1—SIDE DUMP CAR WITH COVER

When the body is filled the cover is applied and the car allowed to stand until the material has solidified. The cover is then removed, the car body is tilted over and the solid cone slides out of the body in convenient form for further transportation.

The accompanying illustration, Fig. 2, shows a striking difference between standard American practice and that of South America in the design of dump cars.

The car shown here is of the square-box, side-dump type, built by the above company for use in the South American nitrate industry.

The cars are of exceptionally heavy steel construction in order to stand up under the severe operating conditions which prevail in the nitrate field.

They are supported on cast steel cradles, designed so that they require a minimum amount of effort to dump and right them. When the car is dumped it tilts to a considerable angle before the door latches are knocked off, thus insuring a clean discharge and causing the load to be thrown clear of the rails.

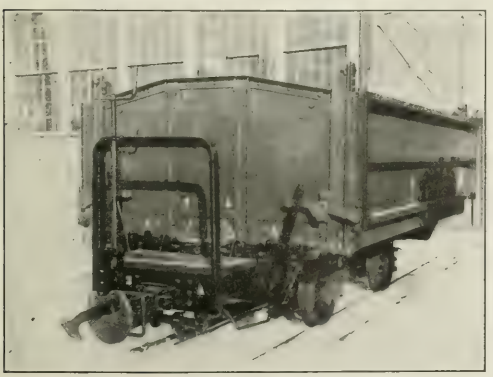

FIG. 2—SQUARE BOX SIDE DUMP CAR

Personal

Mr. **Charles J. Barr,** formerly general superintendent of the Ensley steel plant of the Tennessee company, will be the new general manager of the Fairfield works of the same company.

Dr. **Charles Baskerville,** professor of chemistry in the College of the City of New York, has been appointed by the Ramsay Memorial Committee to organize a committee in the United States for receiving subscriptions to the fund from Americans.

Mr. **W. H. Coghill** of the Bureau of Mines will assist Thomas Varley, superintendent of the Seattle station, in the investigation of ore dressing, which is to be one of the principal lines of work at the Seattle station. Mr. Coghill will continue his work on the molecular physics of flotation as applied to Oregon ores.

Dr. **J. Ehrlich** has been appointed chief chemist of the Verona Chemical Company, North Newark, N. J.

Mr. **A. W. Hudson** of the Phelps Dodge Corporation, Research Staff, has moved to Burro Mountain Copper Company branch to conduct some large scale experiments for the company.

Mr. **J. C. Mooar** has been appointed acting manager of the Atlanta sales office of the Pratt Engineering & Machine Company, owing to the absence of the manager of the office, Mr. J. B. Jacoway.

Mr. **Fred W. Padgett,** who for the past four years has been research fellow in oil, gas and gasoline in the University of Pittsburgh, has been appointed associate professor of chemistry in the University of Oklahoma, where he will have charge of developing a research department in oil, gas and gasoline.

Mr. **E. Gybbon Spilsbury** sailed from New York on July 26 for Central America and expects to be absent until the end of August.

Prof. **Ernest E. Thum** has joined the staff of METALLURGICAL AND CHEMICAL ENGINEERING as associate editor. He is a graduate of the Colorado School of Mines. His first professional experience was as draftsman with the Minnequa Plant of the Colorado Fuel and Iron Company, during the construction of the East mills. From 1906 to 1914 he was employed by the Anaconda Copper Mining Company, first at the Washoe plant as constructing engineer on hydroelectric and water supply development, then as draftsman on the stack and flue system at the Great Falls plant. He then acted as chief civil engineer in the construction of the Tooele plant of the International Smelting & Refining Company, and upon the completion of this work was transferred back to the Great Falls plant, where he was engineer in charge of construction during the reconstruction of the smelter departments of that works. On cessation of operations due to the outbreak of the European war, Mr. Thum became assistant professor of metallurgy at the University of Cincinnati, taking charge of the department of metallurgical engineering in Dean Schneider's Co-operative Engineering College. During his teaching experience, Mr. Thum published "A Practice Book in Elementary Metallurgy" as well as a number of articles in the technical press.

Mr. **John T. Wilkin** has been elected president of the Connersville Blower Company, Connersville, Ind., in addition to his duties as engineer. Mr. Wilkin was one of the organizers of the company in 1892.

CURRENT MARKET REPORTS

The Iron and Steel Market

The stagnation in the iron and steel markets has continued. Practically nothing has been done in scrap, dealers being afraid to buy or sell or even to match sales and purchases. Business in pig iron has been confined to a relatively few small lots for early shipment. There has been no tonnage of the least importance in unfinished steel. Transactions in finished steel have been in small lots for relatively early shipment, together with a very moderate volume of contract business, placed on mill books at inside prices to take care of regular customers.

There has been no demand and likewise there have been no offerings. The producers know they could not sell by trying to force the market. It is a waiting game, and while nothing seems to transpire the fundamental conditions are rapidly lining up for a complete rehabilitation in the market. This is absolutely necessary in order that business may go on. The entire steel output of the country could not possibly be absorbed at the prices lately quoted as the market. Those prices have been fictitious in the sense that they are not applicable to the great bulk of the production. They have been obtained only on relatively small sales to buyers peculiarly situated. Some few make finished wares of such character that the cost of the steel in them, however great, is a mere bagatelle. Other buyers have been fairly well covered at much lower prices, and bought small tonnages at fancy prices to eke out, the average cost of the total being moderate.

A few weeks ago the iron and steel trade was in the throes of discussion whether there would be regulation of prices by the Government. Some authorities did not seem to realize that the Administration had been given no authority to regulate prices, except as to its own purchases. Nearly all expressed the conviction that Government regulation would be very awkward if not impossible. When the iron and steel price control feature was dropped from the Food Control bill in the Senate (the bill as finally approved provides for strict control of coke prices only) the trade began to realize that possibly the market would adjust itself. Scrap prices had started to decline, pig iron had softened, and finished steel prices had ceased to advance, before President Wilson made his appeal for the foregoing of "unusual profits" and for "one price to all." That statement was published July 12. Since then the trade has marveled more and more at the complete stagnation that followed it, and has come to admit that the natural laws of business decree that iron and steel prices must come down to a reasonable level before trading can be resumed.

The President's finesse did not stop with the "appeal" of July 12. An embargo has been placed on the exportation of certain iron and steel products without licenses and it has been intimated that the granting of licenses is to be greatly restricted, while additional commodities may be included in the embargo list. The Government purchases of steel have been made chiefly on the basis of prices to be fixed later. Purchases on behalf of the Entente Allies have been almost entirely held in abeyance. To the keen observer of iron and steel market habits all this appeals as finesse of the highest order. President Wilson has no power to dictate prices for the iron and steel market at large and undoubtedly would prefer that there should be no occasion for such authority to be given or exercised. Time will provide the readjustment through the operation of natural laws.

Reference has been made to the so-called "law of supply and demand." For nearly two years it was a case of demand rather than of requirements. Demand is what the buyer calls for, not what he requires. For nearly two years demand was based upon the buyer's fears, that if he did not buy far ahead he would secure no material when the time came. Now, when that period of fear is fully ended the jobbers and manufacturing consumers generally are found to be fairly well stocked with material. Some jobbers are going far afield to dispose of surplus stocks. Manufacturing consumers have reduced their specifications against current contracts. As to actual requirements in the future it is obvious that there are to be great reductions in many quarters, for instance, practically no new building projects are being undertaken and the railroads are out of the market.

The war requirements in steel are proving to be rather lighter than expected. It is impossible to make close estimates, but some measure of the possibilities may be obtained by considering that last year the production of rolled steel in the United States was 30,500,000 tons while the production in England was 7,500,000 tons. The British production was absorbed very largely in the prosecution of the war, apart from such portion of the 2,400,000 tons exported as did not go to England's allies for war purposes. If the United States should use as much as England, or twice as much, the remainder, for the arts of peace, would be extremely large, and a relatively small decrease in such consumption would release the steel needed for the war. It is to be noted furthermore that while the production of steel ingots in the United States in 1916 was about 41,500,000 tons, the present capacity is about 49,500,000 tons, while nearly 4,000,000 tons is under construction.

The general price readjustment has already started, and quite in accordance with the precedents established in previous declines. Scrap began to decline late in June and pig iron softened somewhat, early in July. In the past few days there have been offerings of unfinished steel at prices much below those formerly ruling, there being offerings of billets at $85, or $10 below the previous market, and of sheet bars at $90, or $15 below the previous market. Declines in finished steel are still to come, quite according to the usual order.

Non-Ferrous Metal Market

Wednesday, Aug. 8.—Prices in most of the metals have remained practically stationary. Copper, tin, lead and spelter are all unchanged.

Copper.—The hot weather affected both the production and consumption of copper. Electrolytic is quoted at 27.50 to 28.25 cents for prompt delivery; 26 to 27 cents, third quarter and 24.50 to 25 cents fourth quarter. Lake remains unchanged at 29.50 cents. The Boston News Bureau estimates the copper refinery production for July as 180,000,000 lb. with the total for the first seven months of the year 1,235,000,000 lb.

Tin.—Straits tin is unchanged at 63.50 to 64.00 cents, with no new developments. Chinese No. 1, 99 per cent is offered at 55 to 56 cents. Banca tin is held at 60.00 to 60.50 cents.

Lead.—The trust price remains at 11.00 cents spot, New York. Independents are, however, offering lead at 10.75. The Government is understood to have purchased 8000 tons more at 8.00 cents St. Louis.

Spelter.—The Government has asked for open bids on 11,500,000 lb. of grade "C" spelter, thereby deviating from its method of purchasing grades "A" and "B" which it decided to purchase at cost plus a fair profit. It will be interesting to watch the outcome of this bidding. Prompt spelter is quoted at 8.75 New York.

OTHER METALS

Antimony, Chinese and Japanese lb.	$0.15
Aluminum, No. 1 Virgin, 98-99 per cent, lb.	.49
Magnesium, metallic, lb.	2.00-2.50

Cadmium, lb.	1.50
Quicksilver, flask	115.00
Silver, oz.	.80¾
Platinum, pure, oz.	105.00
Palladium, oz.	115.00
Tungsten, powder, 95 per cent, lb.	2.80

Chemical Market

COAL TAR PRODUCTS.—While a majority of items under this classification remain in a position that generally favors the buyer, there has been nevertheless considerable activity noted during the past fortnight. The general opinion is that the market will react in favor of the seller with the advent of early fall.

Benzol.—This market has probably represented the weakest spot in the coal tar situation during the two weeks under review. Holders have expressed considerable disappointment with the situation but hope that a demand will shortly develop that will take care of the heavier offerings that have been noted of late.

Aniline Oil.—Values have been a trifle easier in this market but there has been no pronounced drop. There has been a fair domestic demand which has in a way taken care of the accumulated offerings. The export movement has been rather slow.

Paranitraniline.—The movement in this product has been slow and prices are not firm. Production is quite large. *Metanitraniline* in contrast is particularly scarce with practically no production. Preparation is being made however for new outputs.

Toluol.—While there has been some resale material on the market the position is firm and practically all producers are sold out for a lengthy period.

T. N. T.—The government has been buying all trinitrotoluol available and all plants equipped to produce the product have been working to capacity.

Paratoluidine.—There has been a strong and active inquiry noted for this intermediate. The *ortho*, however has moved somewhat slower. *Paranitrotoluol* is another product that has been in active request.

Xylol.—A sluggish market has been noted and pure has been sold at lower prices. Production is considerably in excess of demand.

Solvent naphthas.—While there has been a fairly good demand noted for this solvent there is a big production noted and prices are a shade easier.

Cresylic Acid.—A fair demand is noted for disinfectant purposes and there is also a movement noted to South America. The high duty prohibits imports from England except on order.

Naphthalene.—While there have been several large contracts placed during the interval the demand has not been general. Prices are about the same.

Alpha Naphthylamine.—Quietness prevails, and with the new producers offering prices are lower.

Phenol.—There has been very important business noted during the interval, one manufacturer selling 750,000 lb. in one day. Prices, however, have been shaded to meet buyers' views. The situation looks stronger.

Dinitrophenol.—The production is increasing noticeably and price shading has resulted in an effort to move stocks.

HEAVY CHEMICALS.—Summer dullness has prevailed, but there has been some special activity noted.

Caustic Soda.—An extremely firm tone has prevailed in this market. Manufacturers have sold up and business appears to be in the hands of resellers. Contracts have been in urgent request and there has been a big demand for 1918. All positions on caustic are higher. *Soda Ash*—While the spot market is unchanged futures are higher, and there has been an active and urgent request for 1918 contracts. Speculative buying has been quite pronounced. *Acetate of soda* is pretty well under contract, but there have been no changes of consequence noted. *Bicarbonate of soda* has been in fair demand with prices higher, and some are sold up. *Silicate of soda* has been very strong, as the few producers are sold up. *Sulphide of soda* has been in very active demand for both domestic and export account, and the production is not keeping pace with the demand. *Bichromates* have been in fair demand, with supplies moderate and the market steady. *Bleaching powder* has been very weak, as is usual in the midsummer. Futures, however, are in better request.

Tungstic, basis 100 per cent.	lb.	1.80 —	...
Alcohol, grain, 188 proof	gal.	4 10 —	4.15
Alcohol, wood, 95 per cent	gal.	1.00 —	1.02
Alcohol, denatured, 180 proof	gal.	1 00 —	1.02
Alum, ammonia lump	lb.	.04½—	.05
Alum, chrome ammonium	lb.	.18 —	.20
Alum, chrome potassium	lb.	.35 —	.36
Alum, chrome sodium	lb.	.14 —	.15
Alum, potash lump	lb.	.07½—	.08
Aluminium sulphate, technical	lb.	.02 —	.02½
Aluminium sulphate, iron free	lb.	.03½—	.03¾
Ammonia aqua, 26 deg. carboys	lb.	.12 —	.13
Ammonium carbonate	lb.	.13 —	.14
Ammonium nitrate	lb.	.16 —	.17
Ammonium, sulphate domestic	100 lb.	6.80 —	6.90
Amyl acetate	gal.	4 50 —	4 60
Arsenic, white	lb.	.17 —	.18
Arsenic, red	lb.	.60 —	.65
Barium chloride	ton	85 00 —	90 00
Barium sulphate (Blanc Fixe, powder)	lb.	.04 —	.04½
Barium nitrate	lb.	.11 —	.11½
Barium peroxide, 80 per cent.	lb.	.28 —	.30
Bleaching powder, 35 per cent chlorine	lb.	.01¼—	.01¾
Borax, crystals, sacks	lb.	.07¾—	.08
Brimstone, crude	ton	55.00 —	60 00
Bromine, technical	lb.	.80 —	.90
Calcium acetate, crude	per 100 lb.	5.25 —	5.30
Calcium carbide	ton	80.00 —	90 00
Calcium chloride, 70-75 per cent, fused, lump	ton	30.00 —	31 00
Calcium peroxide	lb.	1.60 —	1.65
Calcium phosphate	lb.	.30 —	.31
Calcium sulphate	lb.	.10 —	.12

Carbon bisulphide	lb.	.06½	—	07
Carbon tetrachloride, drums	lb.	.16½	—	16¾
Caustic potash, 88-92 per cent	lb.	.85	—	87
Caustic soda, 76 per cent	lb.	.07½	—	07⅝
Chlorine, liquid	lb.	.15	—	40
Cobalt oxide	lb.	1.60	—	1 65
Copperas	100 lb.	1.00	—	1 05
Copper carbonate	lb.	.32½	—	35
Copper cyanide	lb.	.72	—	74
Copper sulphate, 99 per cent, large crystals	lb.	.09¾	—	09¼
Cream of tartar, crystals	lb.	.48½	—	50
Epsom salt, bags	100 lb.	3.85	—	4 00
Formaldehyde, 40 per cent	lb.	.17	—	18
Glauber's salt	100 lb.	.72	—	80
Glycerine, bulk, C. P.	lb.	.63½	—	64
Iodine, resublimed	lb.	4.25	—	
Iron oxide	lb.	.02	—	08
Lead, acetate, white crystals	lb.	.16	—	17
Lead arsenate	lb.	.12¾	—	13½
Lead nitrate	lb.	.17½	—	18
Litharge, American	lb.	.08	—	19
Lithium carbonate	lb.	1.02	—	1 05
Manganese dioxide, U. S. P.	lb.	48	—	55
Magnesium carbonate, tech	lb.	.13½	—	14
Nickel salt, single	lb.	.11	—	11½
Nickel salt, double	lb.	.08	—	08½
Phosphorus, red	lb.	1.25	—	1 30
Phosphorus, yellow	lb.	2.40	—	2.45
Potassium bichromate	lb.	.37	—	37½
Potassium bromide granular	lb.	1.35	—	1.40
Potassium carbonate calcined, 80-85 per cent	lb.	.75	—	78
Potassium chlorate, crystals	lb.	.50	—	55
Potassium cyanide, 98-99 per cent	lb.	2.30	—	2.50
Potassium iodide	lb.	2.90	—	2.92
Potassium muriate 80-85 p. c. basis of 80 p. c.	ton	340.00	—	350.00
Potassium nitrate	lb.	.31	—	33
Potassium permanganate	lb.	3.85	—	4.00
Potassium prussiate, red	lb.	2.75	—	2 80
Potassium prussiate, yellow	lb.	1.08	—	1 12
Potassium sulphate, 90-95 p. c. basis 90 p. c.	ton	325.00	—	350 00
Rochelle salts	lb.	.39	—	39½
Sal ammoniac, gray gran	lb.	.10	—	11
Sal ammoniac, white gran	lb.	.15	—	16
Sal soda	100 lb.	1.20	—	1 25
Salt cake	100 lb.	.95	—	1 05
Silver cyanide	oz.		—	
Silver nitrate	oz.	.49⅞	—	50⅛
Soda ash, 58 per cent, light, flat	100 lb.	2.85	—	3 00
Soda ash, 58 per cent, dense, flat	100 lb.	3.75	—	4 00
Sodium acetate	lb.	.09½	—	10
Sodium benzoate	lb.	3.75	—	4.00
Sodium bicarbonate, domestic	100 lb.	2.35	—	2 50
Sodium bicarbonate, English	lb.		—	
Sodium bichromate	lb.	.15⅞	—	16½
Sodium bisulphite, powd	lb.	.04	—	04½
Sodium chlorate	lb.	.23	—	25
Sodium cyanide	lb.	.47	—	50
Sodium fluoride, commercial	lb.	.18	—	18½
Sodium hyposulphite	lb.	.01¾	—	02
Sodium nitrate, 95%	100 lb.	4.27½	—	4.30
Sodium nitrite	lb.	.45	—	50
Sodium peroxide	lb.	.85	—	90
Sodium phosphate (tri.)	lb.	.05	—	05¼
Sodium prussiate, yellow	lb.	.32	—	33
Sodium silicate, liquid—40 deg. Baumé	100 lb	2.50	—	2 60
Sodium sulphide, 30 per cent crystals	100 lb.	3.00	—	3 10
Sodium sulphide, 60 per cent, fused	100 lb.	4.50	—	4 55
Sodium sulphite	lb.	.03¼	—	03½
Strontium nitrate	lb.	.28	—	30
Sulphur chloride, drums	lb.	.06	—	06½
Sulphur dioxide, liquid, in cylinders	lb.	.15	—	40
Sulphur, flowers, sublimed	100 lb.	3.20	—	3 30
Sulphur, roll	100 lb.	2.55	—	2 60
Sulphur, crude	ton	45.00	—	50 00
Tin bichloride, 50 deg.	lb.	.19¾	—	20
Tin oxide	lb.	.64½	—	65
Zinc carbonate	lb.	.25	—	27
Zinc chloride	lb.	.10¼	—	11
Zinc cyanide	lb.	.50	—	
Zinc dust, 350 mesh	lb.	.17	—	19
Zinc oxide, American process XX	lb.	.14¾	—	15
Zinc sulphate	lb.	.05½	—	06

Coal Tar Products (Crude)

Benzol, pure, water white	gal.	.51	—	55
Benzol, 90 per cent	gal.	.50	—	52
Toluol, pure, water white	gal.	1.70	—	1 90
Xylol, pure, water white	gal.	.45	—	50
Solvent naphtha, water white	gal.	.18	—	22
Solvent naphtha, crude, heavy	gal.	.13	—	16
Creosote oil, 25 per cent	gal.	.31	—	33
Din oil, 20 per cent	gal.	.29	—	30
Pitch, various grades	ton	8.00	—	20 00
Carbolic acid, crude, 95-97 per cent	lb.	1.05	—	1 10
Carbolic acid, crude, 50 per cent	lb.	.55	—	60
Carbolic acid, crude, 25 per cent	lb.	.32	—	35
Cresol, U. S. P.	lb.	.25	—	

Intermediates, Etc.

Alpha naphthylamin	lb.	.75	—	85
Aniline oil	lb.	.28	—	29
Aniline salts	lb.	.33	—	34
Anthracene, 80 per cent	lb.	.10	—	
Benzaldehyde	lb.	4 00	—	4 50
Benzidine, base	lb.	1 85	—	2 00
Benzidine, sulphate	lb.	1.55	—	1 60
Benzoic acid	lb.	3.75	—	4 00
Benzyl chloride	lb.	1 75	—	2 00
Beta naphthol benzoate	lb	8.50	—	9 00
Beta naphthol, sublimed	lb.	.80	—	85
Beta naphthylamin com	lb.	2 50	—	
Dichlor benzol	lb.	.11	—	20
Dinitrochlorbenzol	lb.	.44	—	46
Dimethylaniline	lb.	.58	—	60
Diphenylamine	lb.	1 00	—	1 05
H-acid	lb.	3.25	—	3 50
Metaphenylenediamine	lb.	1 75	—	1 80
Monochlorbenzol	lb.	.22	—	24
Naphthalene, flake	lb.	09	—	09¼
Naphthionic acid, crude	lb.	1 50	—	1 75
Nitro naphthaline	lb.	.45	—	50
Nitro toluol	lb.	.50	—	55
Ortho-amidophenol	lb.		—	
Ortho-toluidine	lb.	.90	—	1.00
Para-amidophenol, base	lb.	4.75	—	5.50
Paranitraniline	lb.	1.05	—	1.10
Paraphenylenediamine	lb.	3.50	—	4.00
Para toluidine	lb.	1.90	—	2.10
Phenol, U. S. P.	lb.	.40	—	.42
Resorcin, technical	lb.	8 00	—	9 00
Resorcin, pure	lb.	15.00	—	16 00
Salicylic acid	lb.	1.50	—	1 75
Salol	lb.	1.85	—	2.00
Sulphanilic acid	lb.	.32	—	.33
Toluidin	lb.	3.00	—	
Toluidine-mixture	lb.	.75	—	.85

Petroleum Oils

Crude (at the Wells)

Pennsylvania	bbl.	3.10	—	
Corning, Ohio	bbl.	2.40	—

INDUSTRIAL

Financial, Construction and Manufacturers' News

Financial

New Companies

The All-Steel Wheel Company, Philadelphia, Pa., has filed articles of incorporation under Delaware laws with a capital of $200,000 to manufacture steel wheels. F. R. Hansell, Philadelphia; J. V. Pimm, and S. C. Seymour, Camden, N. J., are the incorporators.

The American Alcolene Corp., Dover, Del., $20,000,000. To deal in all liquids of all kinds, including petroleum.

The American Iron & Furnace Company, Clinton, Iowa, has been incorporated in Delaware with capital of $150,000 to operate an iron furnace and smelting plant. J. E. Moran, F. A. Hohenschuh, T. S. Peterson, Jr., and C. J. Metzger, all of Clinton, are the incorporators.

The American Marbelite Company, Dover, Del., has been incorporated with a capital of $5,000,000 to manufacture composition specialties of vitrous materials. H. L. Mullin, C. L. Rimlinger and Clement M. Egner, Wilmington, are the incorporators.

The American Mine & Torpedo Company, East Orange, N. J., has been incorporated with a capital of $100,000 to manufacture mines and munitions. Gordon Grand, L. Matthews and H. H. Picking, all of East Orange, are the incorporators.

The American Petroleum Co., Baltimore, Md., $1,500,000. To deal in petroleum and its products. The incorporators are Matthew Gault, Harold Tschudi and William D. MacMillan.

The Belleville Metal & Chemical Co., Belleville, N. J., has been incorporated with a capital of $50,000 to manufacture chemicals. Charles and Jacob Bobker and David Silver are the incorporators.

The Berkshire Rubber Company of New York, Inc., Albany, N. Y., has been incorporated with a capital of $10,000 to manufacture rubber goods. T. D. McMurray and A. and B. Wurts, all of Albany, are the incorporators.

The Black Diamond Oil Company, a $25,000,000 corporation, which was recently organized by prominent Western and Eastern capitalists, has been quietly financing and accumulating valuable oil proven and producing acreage in Kentucky, Mississippi, Michigan, Wyoming, Oklahoma, Indiana and the Coastal Oil Belt of Texas. The following companies will be merged under the Black Diamond banner, either by direct purchase or control of stock: The Alcoken Oil Company, Rising Sun Oil Company, Thayer Oil & Gas Company, Wyoming Producing & Refining Company and the Monticello Oil & Gas Company. The holdings of this merger are approximately 800,000 acres, over half of which is owned in fee. Some of the men associated in the deal are C. C. Marshall, Drumright, Okla.; B. M. Robinson, Joplin, Mo.; J. W. Mettler, Chicago; Marion W. Edwards, Casper, Wyo.; E. C. Lott, Chicago; J. D. Cameron, New York; R. H. Owen, Chicago; James A. Wallace, Irvine, Ky.; F. M. Smith, St. Louis; Morris M. Becher, New York; F. W. Church, Jefferson City, Mo.; W. A. Otto, Chicago; L. C. Moch, Casper, Wyo.; Hon. J. M. Hayes, Oklahoma City; Edward Hilp, Louisville; O. A. Kintz and A. C. McClaughry, Chicago.

Briggs & Co., Inc., Providence, R. I.; $5,000. To do a chemical manufacturing business. Incorporators: Annie M. Briggs, Frances A. Rieckel and Willard M. Dean.

The Brooklyn Standard Laboratory, Brooklyn, N. Y., has been incorporated with a capital of $10,000 to manufacture chemicals. P. F. Lahm, P. W. Schumacher and L. Schopfer, 213 Cornelia Street, Brooklyn, are the incorporators.

The Carr Leather Company, Dover, Del., $120,000. To manufacture leather.

The Columbia Fuller's Earth Company, Kettle Falls, Wash., has been incorporated for $20,000, with headquarters in this city. Incorporators are Henry Severin, Herman N. Zapel, Edward Severin and Raymond Zapel, and company will develop a large deposit of Fullers earth near Kettle Falls.

Conewago Chemical Co., Warren, Pa., $75,000. W. G. Heasley, incorporator.

Cosden & Co., Wilmington, Del., $32,000,000. To produce and prepare for market petroleum and natural gas in all forms.

The Diarsenol Company, Inc., Buffalo, N. Y., has been incorporated with a capital of $25,000 to manufacture chemicals. G. A. Webster, A. E. Jones and J. J. Henry, Buffalo, are the incorporators.

Dixie Foundry Co., Cleveland, Ohio, $40,000. To engage in the general foundry business. Incorporators: S. B. Rymer, J. P. O'Neill, J. S. O'Neal, P. B. Mayfield, Chas. S. Mayfield.

Durst Products Company of America, Delaware; $250,000. To deal in oil and natural gas. Incorporators are C. L. Rimlinger, H. C. Mullin, Clement M. Egner, Elkton, Md.

Franklin Founders Corporation, Delaware: $2,000,000. To conduct a general foundry business. Incorporators: F. D. Buck, M. L. Horty, K. E. Longfield, Wilmington, Del.

General Refining Co., Delaware; $750,000. To acquire oil lands and market products of same. Incorporators are Arthur W. Britton, Samuel B. Howard, Louis H. Gunther, New York City.

The Helkulin Chemical Co., 929 Madison Street, Hoboken, N. J.; $7,000. To deal in all kinds of dyestuffs. Incorporators are R. Helwug, C. W. Kuhle, M. Lingren.

High Gravity Oil Co., Delaware, $3,000,000. To drill and market oils. Incorporators: H. I. Mullin, Clement M. Egner.

Indiana Window Glass Co., Vincennes, Ind.; $100,000. To manufacture, buy and sell window glass. Incorporators: F. Bastian, J. A. Sweet, L. A. Meyer and Anton Simon.

Industrial Electric Furnace Co., Indianapolis, Ind.; $500,000. Incorporators: Chas. B. Sommers, Chas. B. Fletcher, F. von Schiegell, F. T. Snyder and S. A. Fletcher. The company will operate its factory in Indianapolis for the manufacture of electric furnaces. The main offices will be in Chicago.

International Sisal & Petroleum Co., New York; capital, $1,000,000. To acquire lands suitable for growing agave, hemp, flax, etc.

The Iron & Ore Corporation of America, New York, has been incorporated with a capital of $250,000 to engage in the production of iron, steel and other metals. V. E. Seipgens, R. R. Ely and J. M. Lowenstein, 11 West Ninetieth Street, are the incorporators.

The Legeim Rubber Company, Jersey City, N. J., has filed articles of incorporation with a capital of $25,000 to manufacture rubber goods of various kinds. F. Losche, A. McMahon and C. B. Hermans, Jersey City, are the incorporators.

The McKeesport Enameling Company, McKeesport, Pa., has been incorporated in Delaware with a capital of $50,000 to manufacture paints and varnishes. A. Clifford Wiltshire, J. R. Woreley and James W. Nesbitt, McKeesport, are the incorporators.

The Machine Composition Company, Philadelphia, Pa., has filed articles of incorporation with a capital of $18,000 to manufacture printing type. B. F. Banes is the principal incorporator.

Merry Oil & Refining Co., Delaware; $1,000,000. To acquire oil lands and develop the same. Incorporators are E. L. Merry, R. A. Moody and L. Harden.

Mitchell Chemical Co., Altoona, Pa., $5,000. W. R. Merrill, incorporator.

Monitor Oil & Refining Co., Delaware; $1,000,000. To acquire and develop oil lands of all kinds. The incorporators are Walter P. Carrow, George T. Maxwell, Local Dover.

The National Synthetic Rubber & Tire Company, New York, has been incorporated in Delaware with a capital of $1,000,000 to manufacture tires and other rubber goods. Arthur W. Britton, S. B. Howard and John A. Moore, New York, are the incorporators.

The National Tractor Company, Georgetown, Del., has filed articles of incorporation with a capital of $2,500,000 to manufacture tractors and parts. C. W. Cullen, Albert Worth and W. Martin, all of Georgetown, are the incorporators.

The Nichols-Vogt Chemical Company, Buffalo, N. Y., has been incorporated with a capital of $25,000 to manufacture chemicals. Charles J. and Dayton G. Vogt, and Walter C. Nichols, all of Buffalo, are the incorporators.

The Nitrogen Fixation Corporation, New York, has filed articles of incorporation with a capital of $1,000,000 to manufacture chemicals and allied products. The incorporators are J. R. Rubin, J. F. A. Comstedt and S. M. Well, 34 Pine Street.

The Penn York Gas & Oil Co., Batavia, N. Y.; $1,000,000.

Pittsburgh-Illinois Oil & Gas Co., Pittsburgh, Pa.; $100,000. W. A. McCoy, Geo. W. Morgan, W. I. N. Lofland.

The Pittsburgh Mining Machine Company, Pittsburgh, Pa., has filed articles of incorporation with capital of $100,000 to manufacture mining machinery. T. H. Edelblute heads the company.

The Procaline Company, Inc., New York, has filed articles of incorporation with a capital of $10,000 to manufacture chemicals. J. E. Vidal, R. G. Contrell and F. L. McIlvaine, 257 West 136th Street, are the incorporators.

The Progressive Machine & Metal Products Company, New York, has been incorporated with a capital of $10,000 to manufacture boilers, machinery, etc. A. Kipness and L. Olitsky, 1517 Fifty-third Street, are the incorporators.

Protection Paint Co., Inc., Brooklyn, N. Y.; $10,000. General manufacturing and sale of paint, varnishes, chemicals. Incorporators are J. Karjian, M. Bartholomew, P. Lamperpoulos, 66 Fifth Avenue, Brooklyn.

The Pyrohodol & Chemical Co., Inc., Chicago, Ill.; $15,000. Incorporators are Samuel M. Come, H. Weintraub, Alfred Weissenbach.

Santa Rita Fuel & Iron Co., St. Louis, Mo.; $500,000.

The Seneca Electric Furnace Corporation of Albany, N. Y., has been incorporated for the purpose of manufacturing and selling electric furnaces for steel making and other purposes. Thornton W. Price is vice-president and general manager and Edwin Corning is treasurer. The New York office of the company is located in the Woolworth Building.

Smelter Steel Co., Seattle, Wash.; $1,500,000. Corwin S. Shank, incorporator.

Sussex Iron & Steel Co., New York; $1,000,000. To manufacture and sell and deal in and with steel, copper, nickel, etc.

Tennessee Manganese Co., Wilmington, Del.; $300,000. To manufacture iron, steel, etc.

The Thermit Welding & Modern Torch Company, Seattle, has been incorporated for $4,000 by T. A. Errett, R. A. Redman, et al, Concern will establish a welding plant in Seattle.

The United Steel & Metal Corporation, New York, has been incorporated with a capital of $100,000 to engage in the manufacture of iron, steel and other metal products. A. Heller, F. Viethardt and M. Sternberg, 906 Broadway, are the incorporators.

Washburn Wire Company, Madison, N. J.; $11,000,000. To manufacture iron, steel, copper and other metals.

The Watts Tool & Machine Company, Turtle Creek, near East Pittsburgh, Pa., has been incorporated with a capital of $100,000 to operate a local works. C. J. Watts, Turtle Creek, is the principal incorporator.

The Wearwell Gasket & Packing Company, Camden, N. J., has been incorporated with a capital of $25,000 to manufacture rubber packing and kindred specialties. Joseph A. Whitney, Eleventh and Linden Streets; John K. Stevenson and James V. Waring, Camden, are the incorporators.

Capital Increases

The Haloid Company, Rochester, N. Y., has increased its capital from $75,000 to $150,000. The company specializes in the production of photographic papers.

The Western Utah Extension Copper Company, Pittsburgh, Pa., has increased its capital from $1,500,000 to $2,500,000 for expansion.

The Champion Paper Company, Watertown, N. Y., has increased its capital from $100,000 to $500,000.

The More-Jonas Glass Company, Bridgeton, N. J., has increased its capital from $100,000 to $250,000 for expansion. The company specializes in the manufacture of bottles and jars.

Construction and Operation

California

MARTINEZ.—Preparations are being made by the Shell Oil Company to begin the $1,000,000 worth of new work on its plant here, including construction of 55,000 barrel steel tanks, for which a contract has been let.

OAKLAND.—The new open-hearth furnaces at the Judson works were started early in July. W. D. Bunker has been made general manager of the entire Judson Company, with charge of both the Emeryville and the San Francisco plants. Mr. Bunker has already begun the work of reconstruction. General plans have been made that will involve an ultimate expenditure of a quarter of a million dollars. The next move that will be made in this reconstruction plan will be the wrecking of the old rolling mill and the construction of a modern steel structure with hollow tile walls. This will cost about $40,000. When this is finished, a complete equipment of traveling cranes will be installed. This will be followed by other reconstruction until the old plant has been entirely demolished and an entirely new Judson works has arisen at Emeryville.

RED BLUFF.—Tehama County is fast forging to the front as one of the greatest chrome producers in the State. For 15 or 20 miles along the coast range of mountains in Tehama County chrome ore crops out at intervals of two or three hundred feet. At the present time this industry is receiving more attention by outside capital than any other metal mined in the north. Already numerous big properties are being developed and at the present time there are three companies shipping ore.

RICHMOND.—E. A. Maas and his associates of Philadelphia and Los Angeles will erect a carbon factory here, which will cost $500,000. Work on the factory will start at once. This is the third carbon plant to locate here, the reason being that much of the material used comes from the Standard Oil refinery.

SAN FRANCISCO.—Byron Jackson Iron Works of San Francisco, Cal., are erecting a new $100,000 machine shop at their plant at West Berkeley. The new shop will be ready for occupancy about Nov. 1.

Idaho

BOISE.—The American Nitrate Company is investigating some sodium and potassium nitrate properties in eastern Oregon, in Lake and Harney counties. A. E. Robinson is superintendent in charge of work. C. R. Cole, Marquette Building, Chicago, is interested.

KELLOGG.—The Bunker Hill & Sullivan smelter was blown in recently, one of the three furnaces being started, a charge consisting of Caledonia ore. The smelter, it is said, is one of the most complete and modern in the world. It cost about $1,000,000. It has been so constructed that it may be enlarged from time to time as the demands make necessary. The first improvement to be constructed will be an electrolytic zinc plant, this having been recently decided upon.

Illinois

FEDERAL.—The Consolidated Chemical Products Company will erect a plant at Federal, just east of Alton, Ill., for the manufacture of salts of zinc and barium.

Indiana

WINCHESTER.—The Woodbury glass factory, which was destroyed by fire at a loss of at least $115,000, will resume operations not later than November 1. This announcement was made following a meeting of the board of directors. The factory will be operated on a much larger scale, and will include more territory.

Kansas

WICHITA.—L. C. Hill, president of the Nith Chemical Company of Lawrence, Kan., was recently here looking for a location for a branch plant. The company manufactures medicinal products.

Louisiana

MONROE.—Edwin E. Binney and other New York capitalists plan the construction of a large carbon plant at Fairbanks City, which will cost $200,000. They have recently purchased an oil and gas lease from the Great Southern Oil Company.

Maryland

BALTIMORE.—The Black & Decker Mfg. Company, 105 South Calvert Street, manufacturer of air compressors, electric drills, etc., has awarded a contract for the construction of a new one-story shop, 60 x 200 ft., at Towson. The Cowan Building Company, 106 Madison Street, Baltimore, is the contractor.

BALTIMORE.—The Maryland Brass & Metal Works has awarded a contract to the Price Concrete Construction Company, Maryland Trust Building, for the construction of the proposed new two-story addition to its plant on Guilford Avenue, 46 x 90 ft., to cost $12,000.

Minnesota

MINNEAPOLIS.—A new chemical plant to manufacture tri-sodium phosphate will be located here in the fall. The new company is incorporated with a capital of $150,000. Other chemicals which will be made include di-sodium phosphate, phosphoric acid and caustic soda.

Nevada

AUSTIN.—The Nevada Austin Mines Company, located at Newpass, twenty-five miles from Austin, will construct a 75-ton cyanide plant for handling of ores. Douglas Muir, metallurgical engineer, has been engaged to draw the plans and superintend the construction of the plant.

New Jersey

CAMDEN.—The Active Chemical Company has removed its works from 1210 Kaign Avenue to a new plant at Ferry and Atlantic Avenues, to provide for increased operations. The company has recently acquired a site of about twenty acres at Mount Ephraim, and expects to commence the erection of a new plant early in 1918. Dr. Edward Kressel, president.

HARRISON.—The Driver-Harris Company of Harrison has filed plans for a foundry in Middlesex Street and Railroad Avenue, to cost $25,000.

HARRISON.—The Crucible Steel Company, South Fourth Street, has awarded contracts to the American Bridge Company for structural steel for additions to its plant, to cost about $75,000.

MAURER.—The American Smelting & Refining Company has awarded a contract for the erection of a new four-story steel pulverizing mill, 55 x 60 ft., to the H. D. Best & Company, 52 Vanderbilt Avenue, New York.

METUCHEN.—The Acme Dyeing & Chemical Company is planning for the erection of an addition to its plant. Charles B. Carman, 406 Main Street, is engineer.

NEWARK.—Fire, July 21, destroyed a portion of the plant of the Cotex Company, 341 Oliver Street, manufacturer of artificial leather, with loss estimated at $10,000.

NEWARK.—Fire, Aug. 2, destroyed the plant of the Roxylite Company, Long Avenue, Hillside district, consisting of about twenty buildings, with loss estimated at $100,000. The plant will be rebuilt. The company specializes in the manufacture of film for motion picture service.

NEWARK.—The Balbach Smelting & Refining Company, Doremus Avenue and Avenue R, will build a new one-story retort furnace at its works.

NEWARK.—The Butterworth-Judson Corporation will build three large one-story extensions to its chemical works on Avenue R, to cost $152,000. Two of the structures will be 140 x 300 ft., and the other, 60 x 445 ft.

NEW BRUNSWICK.—The United States Nickel Company, Allen Avenue, is planning for the construction of an addition to its main plant.

PARLIN.—The E. I. du Pont de Nemours Company has commenced the erection of an addition to its plant for the manufacture of smokeless powder.

ROOSEVELT.—The Tyson Rubber Substitute Company has had plans prepared for the erection of a new plant at Woodbridge.

TRENTON.—The Utah Potash Company, capitalized at $1,500,000, plans the early operation of its new $100,000 plant here. The building is equipped to handle various chemical products.

New York

BALDWINSVILLE.—The Hoffman Paper Company has acquired property on Oswego Street, to be used as an extension to its works.

BROOKLYN.—The Bristol Myers Company, 277 Greene Avenue, manufacturer of chemicals, will build a new one-story plant, 100 x 200 ft., in the Hillside district, near Newark, N. J., to cost about $25,000. Contract for erection has been awarded.

BROOKLYN.—The Chelsea Fibre Mills, 1155 Manhattan Avenue, has awarded a contract for the construction of a two-story brick addition to its plant, 80 x 200 ft., at Manhattan Avenue and Newtown Creek. The Tidewater Building Company, 16 East Thirty-third Street, New York, is the contractor.

BUFFALO.—The Curtiss Aeroplane Company has had plans prepared for a new three-story brick and steel plant to cost about $400,000, to be erected at 1992-2160 Elmwood Avenue.

BUFFALO.—The Wickwire Steel Company is planning for the early operation of its new rod and blooming mill, now nearing completion.

FULTON.—The Arrowhead Mills, Inc., manufacturer of paper, has had plans prepared for a new two-story paper mill, about 80 x 350 ft., to cost $350,000.

NEW YORK.—The General Optical Company, 583 First Avenue, has awarded a contract to A. Barbaresi, 48 South Fourth Avenue, Mt. Vernon, for the erection of a new three-story brick addition, 75 x 275 ft., at First Avenue and Washington Street, Mt. Vernon, N. Y.

NEW YORK.—C. K. Williams & Company, Easton, Pa., have purchased the plant of the Union Carriage & Gear Company for $25,000, and will immediately begin alteration and installation of equipment for the manufacture of rosin size and other paper mill chemicals. Other plants operated by C. K. Williams & Company are located at Kalamazoo, Mich., Holyoke, Mass., Allentown, Pa., Ontario, N. Y., South Carolina and Florida.

SCHENECTADY.—The General Electric Company is planning for the immediate erection of a new one-story foundry, 100 x 110 ft., at its Pittsfield, Mass., works.

SYRACUSE. — The Onondaga Pottery Company, West Fayette Street, is making rapid progress in the erection of new buildings at its plant to form a complete additional unit for manufacturing. Five buildings will be constructed, one four-story, 40 x 130 ft.; two four-story, 40 x 90 ft.; one two-story, 40 x 90 ft.; and one one-story, 40 x 90 ft. It is expected to have the main section of the new extension ready for occupancy in the fall. E. L. Torbert is general manager.

TICONDEROGA.—The Ticonderoga Pulp & Paper Company, North Main Street, will build a one-story, reinforced-concrete addition to its plant, 50 x 150 ft., to cost about $15,000.

Ohio

COLUMBUS.—The Federal Chemical Company has completed its plant in Bonham Avenue, and is ready to occupy the buildings, which cover three acres of the 15 acres in the tract owned by the company. The company will employ 100 persons.

ELYRIA.—The Harshaw-Fuller-Goodwin Company will erect an addition to its plant at a cost of $10,000.

LORAIN.—National Tube Company plans the erection of a benzol plant at this place. Benzol will be made from the 308 by-product coke ovens at the plant.

YOUNGSTOWN.—Extensions of a substantial nature will be made to the plant of the Youngstown Iron & Steel Company, controlled by the Sharon Steel Hoop Company of Sharon, Pa. Plans are rapidly being formulated for these improvements. Two or three open-hearth furnaces will be added, as well as extensions to the finishing departments. Definite plans for these additions will be completed within a very short time. The improvements have been under consideration ever since the Sharon concern acquired the local property. The Sharon Steel Hoop is capitalized at $10,000,000, and it is said to have sufficient capital and other funds available to finance the improvements. They will involve a large outlay and will mean the employment of many more workmen.

YOUNGSTOWN.—Improvements involving the expenditure of $3,000,000 were announced recently by James A. Campbell, president of the Youngstown Sheet & Tube Company. One hundred and two additional by-product coke ovens will be built. The tar products and benzol plant will be increased 50 per cent. The company now has 204 coke ovens, and the additional ones will increase the capacity of this department 50 per cent.

Oklahoma

SAND SPRINGS.—The Mohawk Refining Company will establish another oil refinery, with a capacity of 2000 barrels daily.

Pennsylvania

CHESTER.—The Chester Paper Company will erect a new three-story and basement building, about 155 x 356 ft., at its plant, to be used as a finishing works. The structure will cost about $200,000. The Scott Paper Company, Glenwood Avenue, Philadelphia, operates this company.

LANSDALE.—The Barrows Mfg. Company, manufacturer of rope, cordage and kindred products, has commenced the construction of a new building to be used as a rope manufacturing plant, replacing the structure recently destroyed by fire.

NAZARETH.—The Nazareth Foundry & Machine Company, manufacturer of iron and steel castings and shapes, has been acquired by new interests for a consideration of about $100,000. The new owners are said to be planning to increase the capacity of the works.

PHILADELPHIA. — The Gorgas-Pierle Mfg. Company, 130 East Allen Street, manufacturer of oils of different kinds, will build a five-story brick and concrete addition to its plant, 75 x 155 ft., at 144-64 East Allen Street, to cost about $100,000. The Turner Concrete Steel Company, 1715 Sansom Street, has the contract for erection.

PHILADELPHIA. — Dungan Hood & Company, Inc., American Street, manufacturer of tanned, curried and finished leathers, has acquired a five-story factory at American and Diamond Streets, to be used for plant extensions.

PHILADELPHIA.—Fire, July 25, destroyed a portion of the oil works of the American Refining Company, Point Breeze, with loss estimated at $100,000. The plant will be immediately rebuilt. J. H. Van Dyke is president.

PHILADELPHIA.—Charles Lennig & Company, 112 South Front Street, will build a two-story, brick and steel addition, about 40 x 50 ft., to their chemical plant at Richmond Street and Delaware Avenue, to cost about $11,000.

PHILADELPHIA.—The Penn Paper Products Company, recently incorporated, has filed notice of organization at Camden, N. J., to operate its proposed plant in that city. LeRoy Jacobs, Philadelphia; and Cyrus E. Tomlinson, McKinley, Pa., head the company, which has an authorized capital of $50,000.

PHILADELPHIA. — The Barrett Mfg. Company, manufacturer of chemicals, has awarded a contract to the A. Raymond Raff Company, 1635 Thompson Street, for the construction of a one-story, concrete and brick addition, 87 x 100 ft., at Bermuda and Margaretta Streets, to cost $40,000.

PITTSBURGH.—The Pittsburgh Steel Products Company is planning a new plant, including a new town on Monongahela River. It is planned to expend about $3,000,000. Several farms in Allen township, opposite Fayette City, were purchased some time ago. A battery of blast furnaces, tube mills and other departments will be installed. The plant will have a river frontage of three miles. The president of the company is Willis F. McCook of Pittsburgh.

READING.—The Republic Color & Chemical Company, operating a number of plants in New England, will erect a factory here. The factory will include five buildings. John D. Esterly of Reading heads the company.

ST. MARYS.—The recent demand for electric furnace electrodes has come to the attention of the Stackpole Carbon Company at St. Marys, Pa., and their production department, after making many experiments, has developed a carbon graphite electrode, called "Stackpole Special," which has a high current-carrying capacity, and is being introduced extensively throughout the industries employing electric furnaces. The great demand for ordinary and special steels has brought about an intense demand for electrodes, and with the intention of meeting this demand the Stackpole Carbon Company has completed a large unit to their big plant, with the object of coming to the aid of the many who must have electrodes to operate. This new plant is equipped with machinery and furnaces to handle all sizes, both square and round, up to and including 17 inches in diameter.

At present the concern is daily producing large quantities of 4, 5 and 6-in. diameter electrodes. These are being made up of a composition which they have found offers a close substitute for graphite as regards the interchange of sizes, and it is interesting to note that these electrodes of a carbon graphite composition are being used in the place of graphite. The comparative diameters of the "Stackpole Special" electrode to the graphite is working successfully at 6 to 4, which fact is of engineering interest in view of the fact that so much smaller sizes as compared with the old carbon electrode can be used in the place of graphite. This ratio of diameters, when used, has given quicker heats with the same power consumption per ton in the case of the "Stackpole Special" than with the graphite, and confirms the production department's views that they have eventually solved the problem of the sort of electrode which will take care of the present shortage without resorting to the use of the old huge size carbon electrodes and consequent redesign of hundreds of electric furnaces.

Tennessee

BRISTOL.—Manufacturing will begin immediately in the new plant of the Chas. A. Schieren Company of New York City, built as an addition to its tannery at Bristol, Tenn. The buildings are entirely completed, and the equipment of machinery is being installed for the manufacture of the highest grade machine belts, the greater portion of which will be shipped to Southern plants. A working force sufficient to produce 24,000 lineal feet of belting daily will be employed at the start, and gradually added to, as skilled help can be secured, until the full capacity of the plant, 50,000 feet daily, is reached.

Texas

DENISON.—Construction work has begun on the mill and warehouses of the Peters Oil & Refining Company, to manufacture oil from peanuts. The mill building proper will be constructed of steel and brick, and will be 40 x 70 ft. The warehouses will be much larger than the mill, and will have a capacity of several hundred carloads of peanuts. The storage of peanuts will be large enough to insure operation of the plant throughout the year. The company, which was recently organized, will specialize in milling peanuts, beans and other vegetable products.

Utah

GUNNISON.—The Gunnison Valley Sugar Company is planning the erection of a sugar factory in this valley. It will have a capacity of 600 tons, and will be completed in time for the next year's crop. The company was recently organized, and is capitalized at $1,325,000. The officers are as follows: President, W. O. Kay; secretary, I. C. Thoreson, United States surveyor general for Utah; treasurer, W. H. Swanson, president of the Swanson Theater Circuit; additional directors, James P. Sprunt, Dr. A. C. Wherry, W. M. Johnson and Max Aniels. All of the officers are of Salt Lake.

SALT LAKE CITY.—Thomas B. Keeley of Chicago, who has a large number of patented iron ore claims in Iron County, and who owns 2100 acres of coal in the vicinity of Sunnyside, recently made an inspection of the properties and consulted with his engineers in regard to the advisability of erecting a steel plant near the Salt Lake City limits or on the shores of Utah Lake.

Virginia

IVANHOE.—The National Carbide Corporation of Bluefield, W. Va., will erect a plant here that will have an annual production of 15,000 tons of carbide. The plant will be built immediately, and will be completed within six months.

Washington

CENTRALIA.—R. Thomas of Portland, president of the Thomas Pulp & Paper Company, a $5,000,000 corporation just formed, announced that his company has completed arrangements for the erection of a 40,000 horse power plant and paper mill in Aberdeen. A new process of making all kinds of paper out of red fir has been invented by Mr. Thomas. The power plant will be located here. He says his company has purchased 300 acres of coal land in South Hanaford Valley and will mine its own coal, 500 tons of which will be needed daily.

SEATTLE.—A new corporation with a capital of $20,000,000 for building iron ore smelters, steel mills and blast furnaces on Lake Washington near Seattle, has been organized in San Francisco. It is possible that some of the iron ore will be obtained from Stevens County, northern Idaho and British Columbia. Some of the men interested are well known in Spokane, among them being William H. Crocker of San Francisco, who is interested with R. S. Talbot of Spokane in magnesite operations in Stevens County. Others who are said to be in the new organization are D. C. Jackling, William G. Devereaux, D. P. Hoak, S. F. B. Morse, B. L. Thane of San Francisco, and William Pigott of Seattle. Smelters, blast furnaces and steel mills will be built at Seattle, where the new company has 500 acres. The Pacific Improvement Company already has been given contracts for coal to be secured in Washington and which is said to be of a high coking quality. Gas ammonia, tar and other by-products will be manufactured.

Wisconsin

RACINE.—The Racine Rubber Company is building extensions to its works to increase the present capacity for the manufacture of automobile tires.

Canada

SUDBURY, ONT.—An enormous nickel smelter and refining plant will be constructed by the British-American Nickel Corporation about 4½ miles northwest of Sudbury. A large amount of Toronto capital will be invested in the new concern, though the British government controls $14,000,000 of the $20,000,000. It is estimated that within two years the corporation will be able to produce 6000 tons of refined nickel annually, and according to a statement made by E. P. Mathewson, general manager, the entire output is to go to the British government, the International Nickel Company being at the present time its chief source of supply.

Manufacturers' Notes

THE BYRON JACKSON IRON WORKS, San Francisco, Cal., has moved its general offices from 357 Market Street to the Sharon Building, on New Montgomery Street, directly opposite the Palace Hotel.

ELECTRIC HOISTS.—The Link-Belt Company, with factories in Chicago, Philadelphia and Indianapolis, and sales offices in the principal cities of the country, announces its ability to again furnish Link-Belt Mono-rail electric hoists for quick shipment. These machines are made at the Philadelphia plant, where a large additional building is rapidly nearing completion and the present manufacturing facilities are being greatly increased. Both types, C-1 and C-2, can be furnished, the safe lifting capacities ranging from 1000 lb. to 6000 lb. They can be adapted for either direct or alternating current and fitted with plain, hand-geared, cord-operated motor, or a cage operated motor trolley.

FEDERAL TRADE COMMISSION'S COPPER COST INVESTIGATION NEARING COMPLETION.—The Federal Trade Commission's investigation into the cost of producing copper, under supervision of Commissioner Colver, is progressing favorably. Dr. L. H. Haney is in direct charge of the details of this phase of the commission's investigation of metal costs. The field reports are now coming in rapidly and the commission hopes to have all reports in and results ready for submittal to the President within another week. None of these figures will be given out at the commission. If given out at all they will be made public at the White House.

THE GLENS FALLS MACHINE WORKS, which have been making a successful sulphur burner at Glens Falls, N. Y., have consolidated with the F. R. Patch Manufacturing Co., Rutland, Vt. The business of the Glens Falls concern will be carried on under the old name, the offices remaining at Glens Falls, except the treasurer's office, which will be at Rutland. The officers are: President, F. R. Patch; vice-president, Newman K. Chaffee; treasurer, George C. Cobb; secretary, E. A. Hall; works manager, Fred B. Chappell. Their products consist of the Tromblee & Faull rotary sulphur burner, Monarch rotary screen, A. D. Wood pulp washers, slushers, water filters and save-alls, Standard wet machines, Standard ground wood wet machines, wood pulp grinders, rotary pumps, etc. In addition to the works at Glens Falls the consolidation gives the organization a large modern plant in Rutland employing from 250 to 300 men, and increases the producing capacity about three times.

CLEANING INDIA INK FROM TRACING CLOTH.—An article manufactured by E. H. Anderson at 272 East 199th Street, New York, under the name of "Rasindia" is claimed to completely clean India ink from tracing cloth, without injuring the cloth.

C. W. LEAVITT & CO., 30 Church Street New York, as buying agents for foreign clients, are interested in receiving catalogs and quotations for export, on oil- and tar-heated furnaces for tempering and anneal-

ing steel. Also covering furnaces for hardening tool or high-speed steel, and pyrometers and other apparatus useful in the production of high-grade steel.

CORRECTION ON GENERAL BAKELITE CO.—In our last issue (Aug. 1), page 150, under Perth Amboy, N. J., it was stated in a notice of an addition to its plant that the General Bakelite Co. was a subsidiary of the Roessler & Hasslacher Chemical Co. This statement is incorrect as the General Bakelite Co. is an entirely separate company and not controlled by any other company. The general offices are at 2 Rector St., New York City.

HUMIDITY AND DEW POINT PATENT.—The Buffalo Forge Company, Buffalo, N. Y., has issued a statement that the United States District Court has recently sustained the Carrier patent on its dew point and humidity control.

"Suit was brought against the City of Buffalo and Thomas & Smith, Inc., contractors on two installations which the Buffalo Forge Company claimed to be infringements on the Carrier patent.

"The claims cover the automatic regulation of humidity, so as to maintain a constant dew point or saturated temperature by means of bringing air into intimate contact with water heated above the temperature of the water to accomplish the desired result, i. e., the water temperature is variable so as to produce a constant saturated temperature of the outgoing air.

"The court holds that it is not essential that this water should be sprayed into the air, since the defendant's infringements consisted of a tank of hot water which, overflowing, mingled with the unheated water from the spray nozzles, thereby producing the intimate mixture which our patent covers.

"The Buffalo Forge Company consider that heated spray water at a variable temperature, which is controlled by thermostat at the bottom of the eliminator, is an infringement, but a thermostat submerged in the middle of a tank does not infringe, as this would tend to keep a constant temperature of the spray water at a variable temperature with a *constant water temperature* the air temperature would vary from time to time—and humidity control could only be obtained with an additional thermostat.

INDUSTRIAL ALCOHOL DIVIDENDS. Directors of the United States Industrial Alcohol Company at their meeting Aug. 2, declared a cash dividend of 16 per cent on the common stock for the year 1916, a dividend of 10 per cent for the current year, and indicated that hereafter annual dividends of 16 per cent would be distributed.

The first 16 per cent dividend is payable out of surplus accumulated prior to Dec. 31, 1916, and will be paid on Oct. 1 to stockholders of record on Aug. 20, while the second disbursement of 16 per cent, which is for the year 1917, is payable Dec. 1 to stockholders of record on Oct. 20.

The operating income of the United States Industrial Alcohol Company in 1916 amounted to $6,727,043. The net income was $4,884,587, and after payment of 7 per cent dividends on the preferred stock, which has ruled since 1907, the year following the company's organization, the surplus remaining for dividends on the common was $4,336,025. This amounted to 36.14 per cent on the $12,000,000 of common stock.

In the last seven years the company has earned an average of 9.39 per cent. on its common stock, but in recent years the profits have been far above the average. The figure 36.14 per cent for 1916 compares with 12.6 in 1915, and 1.94 in 1914. The expansion in the company's business has been due to the war, with its demand for high explosives, in the manufacture of which alcohol is essential.

"The company's building and development program has now been practically completed," stated Horatio S. Rubens, chairman of the Board of Directors, in announcing the dividend. "The floating indebtedness of the company has been extinguished and the output for the current year has been satisfactorily and firmly sold. The company has set aside out of earnings for the first half of 1917 the sum of $1,500,000 as a reserve to cover Federal corporation taxes. It was decided to declare a dividend at a rate which, it now seems reasonable to expect, can be maintained under after-war conditions, owing to the entry of the company and its various subsidiaries into additional fields of production, which promise to be profitable under peace conditions."

The company erected the largest distillery in the world at Baltimore last year, in order to take advantage of the war business, and also, at the same time, embarked on the manufacture of acetone, which is used in the manufacture of munitions of various descriptions. The company was able, it is understood, to obtain European contracts for its enlarged output on highly favorable terms, and since the entry of the United States into the war it has been gossip that its orders from the United States Government have been enormous.

AMERICAN BRASS ENTERS BUFFALO.—The Buffalo Copper & Brass Rolling Mill has been sold to the American Brass Company. The plant was taken over by the new owners on July 1 and increased operations will be started as soon as possible.

Announcement of the transaction was made a short time ago by William A. Morgan, president of the Buffalo company. The purchase price was not made public. Charles F. Brooker, president, represented the American Brass Company.

As Mr. Brooker is chairman of the brass committee of the National Defense Board, it is expected the plant will have much to do with the manufacture of brass products for the Government.

The Buffalo plant is the latest addition to the series owned and controlled by the American Brass Company. The concern operates three plants in Waterbury, Conn., two plants in Ansonia, Conn., one in Torrington, Conn., and one in Kenosha, Wis.

It is said special inducements were made by the city of Cleveland to have the brass corporation settle there, but Mr. Morgan drew the officers' attention to this city.

The advent of the American Brass Company into the industrial field of Buffalo is looked upon with favor by local manufacturers. It insures the permanency of the industry which Mr. Morgan has built in three years from a small foundry to an industry which now employs more than 5,000 men.

This Buffalo company has been engaged in the manufacture of brass products for foreign governments for almost three years. When the foreign business began to drop Mr. Morgan thought it best to transfer his plant to an organization which is especially trained for home business.

TO OPEN WASHINGTON OFFICE.—The Jones & Laughlin Steel Co., Pittsburgh, has opened a district sales office in the Woodward Building, Washington, D. C., in charge of H. F. Holloway, who is district sales manager of the New York office of the company, and who will also hold the same title in the new Washington office. Mr. Holloway will be assisted by Ralph T. Rowles, who was formerly connected with the Philadelphia office, and covered the Washington, D. C., field. Mr. Rowles will now have his headquarters in the Washington office.

BON AIR COAL & IRON CHANGES HANDS.—The Bon Air Coal & Iron Corporation will be organized with a capital of $10,000,000 to take over the Bon Air Coal & Iron Co.'s properties at Allen's Creek, Eastland, Bon Air and Ravenscroft, Tenn., which have been in receivers' hands for seven years. The new company plans to improve the two stacks and six Gordon hot-blast stoves which the old company operated at Allen's Creek and will add two more stoves, increasing the output to 200 tons a day. At Eastland the company had 200 beehive ovens which produced 80,000 tons of coke a year. The coal mines of the corporation are located at Bon Air, Ravenscroft and Eastland, and it is the purpose of the new owners to increase the output of coal to 10,000 tons a day. Included in the purchase are 27,000 acres of timber land in Wayne County, Tenn., and this property is reported to contain rich ore deposits which will be developed later. The officers of the Bon Air Coal & Iron Corporation are Alex. R. Peacock, New York, president; W. J. Cummins, Nashville, vice-president; A. J. Moreland, Pittsburgh, secretary and general manager; John McE. Bowman, New York, treasurer and chairman. Mr. Peacock was formerly vice-president and sales manager of the Carnegie Steel Co., and Mr. Moreland was formerly connected with the same company. Mr. Bowman is a leading New York hotel man.

ONTARIO POWER CHANGES HANDS.—The Provincial Hydro Electric Commission of Ontario has taken over the plant of the Ontario Power Co., at Niagara Falls, Ont. The plant was recently purchased by the Commission at $22,000,000, of which $13,000,000 is represented in bonded indebtedness to the company, and it is understood, will form an important link in the Chippawa Creek-Queenston Heights development scheme, the ultimate capacity of which will be 900,000 hp. The Ontario Development Co. has a franchise development of 180,000 hp.

Manufacturers' Catalogs

THE B. F. GOODRICH COMPANY, Akron, Ohio, has issued an attractive booklet on rubber goods for mining, describing a wide variety of rubber products.

THE ELECTRIC WEIGHING COMPANY, 180 Thirteenth Avenue, New York, has issued Bulletin No. 10, describing Messiter Conveyor Scales for automatic weighing.

CHAS. A. SCHIEREN COMPANY, Cliff and Ferry Streets, New York, has issued a Belt Buyers' Guide containing valuable practical information on the use and care of belts.

AMERICAN STEEL EXPORT COMPANY, Woolworth Building, New York, has issued a booklet entitled "Export Engineering and Contracting."

CHICAGO PNEUMATIC TOOL COMPANY, Fisher Building, Chicago, has issued Bulletin 137 describing the Chicago Giant rock drill, tappet type.

SHEPARD ELECTRIC CRANE & HOIST CO., Montour Falls, N. Y., has issued a comprehensive booklet on hoisting machinery for industrial works.

TAYLOR INSTRUMENT COMPANIES, Rochester, N. Y., has issued a booklet on Tycos base metal thermo electric pyrometers.

PALO COMPANY, 90 Maiden Lane, New York, has issued a pamphlet describing the Hess-Ives Tint Photometer.

ROBINS CONVEYING BELT COMPANY, 13 Park Row, New York, has issued a handbook of conveyor practice giving considerable valuable information.

PITTSBURGH INSTRUMENT & MACHINE CO., 101 Water Street, Pittsburgh, Pa., has issued a pamphlet describing the Pittsburgh Metal Sheet Tester.

FRUEHAUF TRAILER CO., Detroit, Mich., has issued a booklet on the Fruehauf trailer for carrying up to 10 tons.

HARDINGE CONICAL MILL CO., 120 Broadway, New York, has issued catalog No. 7, Section 1, giving general information on Hardinge mills.

F. J. STOKES MACHINE CO., Philadelphia, Pa., has issued an attractive catalog on vacuum dryers and chemical apparatus.

President Wilson's Reply to the Pope

"We seek no material advantage of any kind. We believe that the intolerable wrongs done in this war by the furious and brutal power of the Imperial German Government ought to be repaired, but not at the expense of the sovereignty of any people—rather a vindication of the sovereignty both of those that are weak and of those that are strong. Punitive damages, the dismemberment of empires, the establishment of selfish and exclusive economic leagues, we deem inexpedient, and in the end worse than futile, no proper basis for a peace of any kind, least of all for an enduring peace. That must be based upon justice and fairness and the common rights of mankind.

"We cannot take the word of the present rulers of Germany as a guarantee of anything that is to endure unless explicitly supported by such conclusive evidence of the will and purpose of the German people themselves as the other peoples of the world would be justified in accepting. Without such guarantees, treaties of settlement, agreements for disarmament, covenants to set up arbitration in the place of force, territorial adjustments, reconstitutions of small nations, if made with the German government, no man, no nation, could now depend on."

Amen! So mote it be!

Particular Phases in the Present Labor Situation

The present labor situation, in its broadest sense, is a mixed up and complicated affair. Not being characterized by a single pre-eminent idea or tendency, it exhibits rather a number of peculiar isolated phases which apparently have little to do with each other and yet must be more or less interconnected. Neither between different industries, nor between different branches of the same industry, can a straight standard of comparison in the form of a unit of salary be employed.

In these columns we have alluded before to the fact that young chemical graduates are now able to draw a monthly salary of $200 in certain industries prospering on account of the war. Whether this is a good thing for them, or not, is very hard to decide in general. But it is just as true that there are classes of hard-working, earnest, able and competent chemists whose salaries have been raised but little, if at all, by the war. This may seem "unfair," but the reason will be understood when it is considered that the selling price of a chemical training, as an economic commodity, depends on various factors, a great many more just now than a few years ago.

It is said that the economic value of an article for sale consists of form value, place value, and time value.

Form value is the value contributed by the manufacturer by changing the raw material into the finished product. Place value depends on transportation; time value on storage possibilities. The classical illustration of the latter two is ice; ice in the Maine woods in winter has no economic value, because nobody is willing to pay money for it there and then; brought to New York, the ice acquires place value; and if it is stored for sale in summer, it acquires additional value—time value.

If a student acquires a thorough chemical training he becomes in certain respects a new man (form value); his training enables him to carry out those processes which comprise the field of chemical technology, and because a knowledge of this correct application of chemical technology is of greatest importance in very many industries at present, the form value of a chemical training as an economic commodity has increased; the average salary of a chemist for the same work done has gone up. This has been true for quite a series of years, but in the last few years place value and time value have attained additional importance.

Place value has become important because the number of positions in which chemical training can be profitably employed has very greatly increased. It is now much easier to take a chemical training to some other place for financial exploitation; we only need remember the recent exodus of the chemical professors from the universities to the industries. We do not want to discuss how bad or good this will be for chemistry in the long run, our only object was to state the facts and their relation to the "chemical labor market." The consideration of "time value," on the other hand, acts somewhat like a balance wheel. It is rather risky now to rely on the permanency of some of those high-salaried war positions. And this uncertainty as to shifting from one position to an equally well or better salaried hypothetical position some time in the future is an important element in shaping the future labor market. For a new chemical labor market is now in the making.

Now let us turn for a moment to an entirely different and new problem of the metallurgical labor market. For many years the iron and steel industry of this country has depended to a large and essential extent on immigrant labor. When this was shut off by the war a substitute had to be found, and it was found in colored labor imported from the South. The Steel Corporation is said to have adopted this remedy first, and the independents to have followed suit. But the historical details do not matter. The principal fact is that the operating men of the iron and steel industry will have a new problem on their hands when the war is over—the race problem. For various recent occurrences have made it once more clear that this country has a race problem, and that it is nowhere near solved.

When the war ends, the whole aspect of the labor situation will be completely changed. But whether the war ends soon or not, it will pay now to watch intelligently any new particular phase coming up in the labor situation.

Allotting the Steel Output

While the steel manufacturers evince what may be described as an indisposition to sell steel to our European Allies at the prices to be paid by our own Government, they are vigorously opposed to the "one price for all" doctrine as regards sales to ordinary domestic consumers. They assert, in the first place, that "it can't be done," and follow this apparently conclusive dictum with other arguments, possibly forgetful of the fact that last February there was opposition to the naming of special prices to the Government on the ground that this would bring down the outside market, as ordinary consumers would refuse to pay more than the Government, they being supposed to remember our Government's liberality in purchasing supplies for the Spanish-American War.

There are two opposite views as to the future of the steel demand, say over the next twelvemonth, one being that there will be a continued shortage of steel, and the other that there will be an ample supply after the present pressure has experienced further relief. If the first view prove correct, regulation of steel deliveries will be highly desirable; if the latter, no particular harm could result from the work having been undertaken.

President Wilson's appeal of July 12 that there should be "one price for all" was predicated on the view that we are all engaged in the war and all must be protected from contributing abnormal profits to producers, whether of coal, of steel, or what not. This would be true if it were possible to allot a share of the war work to every one in the country, and every one was doing the work allotted to him, but such is not the case and cannot be the case. If it were, the country would not be consuming an amount of steel equal to the capacity minus the tonnage required by our Government and our Allies.

The fact is that the activities of the people consuming steel represent wide variations of indispensibility. The users of steel pass by almost infinitesimal gradations from direct connection with the war to a position diametrically opposed to its most efficient prosecution. One man may build farm machinery which will help to increase next year's crops, while another may wish to build a department store, to employ men, when the existing stores, under the kind patronage of Washington, are asking their customers to carry home their parcels and release drivers to go to the front.

In these circumstances it is clear that if the Government is interested in the prices the domestic consumers of steel are to be expected to pay it should be still more interested in the matter of who is to receive preferential treatment in deliveries. It would not be difficult to set up a general set of rules to govern deliveries. Certain questions might be asked: Will it help prosecute the war? How much and what kind of labor will its fabrication or employment involve? What inconvenience would result if the delivery were delayed three months? Six months? The steel mills, as a rule, are quite familiar with the operations of their customers, and at all times the great majority of mills

make a serious and intelligent effort to distribute their steel in such manner as to keep the wheels of industry moving. They would be in excellent position to co-operate with the Government were a set of rules established for the distribution of the steel.

One of two things will occur. Either the matter of steel prices will be left to the open market for settlement, or there will be legislation, as there has already been for "food, feed and fuel," empowering the administration to fix the schedule. In the former case it is obvious that the buyer who bids the highest price is no more likely than not to be the one who will use the steel to best advantage in furthering the work of war. The steel may easily be a selfish luxury for him. In the latter case, regulation of deliveries is absolutely necessary, because otherwise the distribution would be left to the chance of the man who made the earliest purchases.

We referred a month ago to the fact that the friction, the unfavorable items about the conduct of the war, are kept ever before us, while of the actual accomplishments little or nothing is said. The observation is applicable also to the relations between the steel industry and the Government. The Washington dispatches are full of the "controversy" over steel prices. Scarcely anything is said of one magnificent piece of work that has been carried out by purely co-operative methods, Washington having technically no authority whatever. In the early stage of the war preparations it became apparent that it would be desirable to encourage canning the maximum amount of the perishable crops. The Government had no occasion to buy tin plate or to regulate its distribution, but it requested the tin-plate mills to divert to the perishable food products all the tin plate that could possibly be used. The mills did so. They passed up opportunities to sell tin plate at fancy prices. They explained to customers who used tin plate for other purposes that they would have to wait, and the other customers have waited. At the beginning of July the authorities at Washington saw that the situation as to perishable foods was well in hand, and authorized the mills to extend their deliveries to packers of non-perishable foods, and this in turn was done. The tin-plate makers even suggested to customers who were asked to wait that they experiment with fiber containers, knowing full well that some of them might never return to tin plate. All this was done with a minimum of friction and of publicity. It furnishes a lesson as to what can be done on a vastly broader scale with steel products in general if the work is taken up in the proper manner.

Save the Sulphuric Acid

To the man on the street the fact that there is a shortage in sulphuric acid seems hardly worthy of remark; it is immediately classed with those countless other stringencies, real, artificial or bogy, bestirring themselves to pester these troublous times. But the technical man, whether or not an acid user, cannot help but blink when he learns that during the next twelve months the United States is expected to produce eight million tons of acid, with sulphur in sight for only five.

A largely increased demand for sulphuric acid has resulted from the extraordinary expansion of our chemical and explosives industries; a largely decreased supply of sulphur has resulted from the U-boat menace. Formerly, empty shipping returning to America would bring as ballast at the very lowest rates, cheap Spanish pyritic ores, much of which had been mined and leached especially for its copper content. No more shipping, no more foreign pyrite. Even the embargo stopping Canadian paper-makers' supply of sulphur will have small effect on the situation, even though it causes frenzied distress signals from that great American extravagance labeled "Fifth Extra."

Expected shortages might be met by increased production. Mining engineers are not very sanguine of the possibility of getting much more sulphur from the wells of Louisiana, nor of a quick increase in pyrite mining in the Appalachian region—for the acid works are built close to the docks, now bare of Spanish ore, and to the consumers, now with an apparently insatiable appetite.

It is a matter of great regret that the untold quantities of sulphides mined and smelted in the Mississippi Valley and Rocky Mountains cannot permanently furnish our needed sulphur. While approximately one and a half million tons of acid are now made from roaster gases, this is about all that the local market will absorb in the smelter regions, and acid is bulky and cheap and will not normally stand heavy freight charges. Abnormal conditions cannot produce additional acid-making capacity instantly, nor even after a term unless the maker is assured of writing off his plant-cost before the end of the boom. Nor is the time ripe to consider smelter smoke as a source of elemental sulphur, and some other projects for getting the "weak atom" of sulphur from pyritic ores are in the formative stage.

It does seem, however, that a very large amount of liquid sulphur dioxide could be recovered from flue gases by easily constructed plants after the well-established method mentioned in Mr. Ridge's article on page 221. This could readily supply the entire sulphite requirements of paper-pulp makers, who should be glad to use it, now that Louisiana sulphur is so scarce and expensive. A very pure product could be made, especially at plants which precipitate the fume from the flue gases.

Lacking a necessary supply, the next step is to use substitutes and to economize in the use of indispensable acids. In the latter case, especially, the chemical engineers can do much in insisting upon saving and concentrating the enormous amounts of partially spent acid daily running to waste. On the other hand, metallurgists can eliminate practically all fresh acid from their pickling baths, by the use of the acid sodium sulphate from niter cake. Many articles really do not need pickling at all, while many more could be as efficiently and economically cleaned by rumbling, sand blasting or electrolysis.

A Criticism of the Chemical Exposition

To the Editor of Metallurgical & Chemical Engineering

Sir:—The Second Exposition of Chemical Industries was pronounced a decided success, and now the third is soon to be opened. There is no doubt but the third show will be a success as well, but there is also no doubt that it will be more of a success if any features can be avoided that have been a source of dissatisfaction in the past. Of course, it is a physical impossibility to carry out anything on such a large scale as this without an occasional visitor being dissatisfied with something or other, but at the last show one feature confronted me with such persistence that I cannot help thinking that it must have been a source of annoyance to others as well, and that it ought to be called to the attention of the general body of exhibitors at the show.

The object of these expositions, as I understand it, is mainly to advertise the products of the exhibitor and to bring the buyer and seller into closer relations with each other. Of the two, the latter seems to me the more important, and to the extent that the exposition fails to accomplish this end it is a failure.

I came to the exposition last year very much interested in three particular things. Of course, I went over the entire show, and was in a large proportion of the booths of the various exhibitors, but these three materials were my main items of interest. I went to the booth of one of the leading jobbers that had the first of these materials on exhibition, and after some discussion of the matter stated that I wanted to leave an order. The attendant, after fumbling around through a number of papers, announced that he had no quotations on what I wanted, and that it would be better if I filed a request for a quotation and then sent my order on receipt of quotation. I did so, but it has been over ten months, and the quotation has not yet arrived.

I went to a second booth, and, after some inquiries concerning the suitability of their product for the work that I had in mind, I left with them an order for a small quantity of their product for trial. That also was ten months ago, but the material has not yet been received.

At a third booth I explained that I was doing some experimental work for which I needed certain of their products, and left an order. That material also is still to arrive.

In every case the material ordered was standard goods, regularly carried in stock, and on exhibition in the booth. None of it was to be special in any way.

Does not a 100 per cent failure at least give one a reasonable excuse for complaint?

South Bethlehem, Pa. G. A. Roush.

Determination of Chromium and Vanadium in Steel

To the Editor of Metallurgical & Chemical Engineering

Sir:—The determination of vanadium in presence of iron and chromium has proven rather difficult for routine work. The method herein described has proven satisfactory both for accuracy and speed. Credit for priority for the determination of chromium is due to Phillips (*Stahl und Eisen*, Vol. XXVII, pages 1164 to 1167) and H. E. Walters (Metallurgical and Chemical Engineering, Vol. XII, No. 5, page 310). The determination of vanadium is made after chromium has been oxidized. The vanadium is reduced by ferrous sulphate, the excess of which is oxidized by ammonium persulphate. The vanadium is then oxidized by standard potassium permanganate, from which the percentage of vanadium can readily be calculated. The details follow:

CHROMIUM

Two grams of the sample are transferred to a 600 c.c. beaker, and 60 c.c. sulphuric acid and silver nitrate mixture added. Heat is then applied until all action ceases. If vanadium is present 5 c.c. of syrup of phosphoric acid are added. Then 10 c.c. of nitric acid (1.20 sp. gr.) are added and the solution is boiled until the fumes are expelled. The contents of the beaker are then diluted to a volume of approximately 300 c.c. with boiling water, the solution then heated to boiling, and 10 c.c. ammonium persulphate solution added. After the permanganate color has developed, 1 c.c. of conc. hydrochloric acid is added, and boiling continued until the pink color disappears and until persulphate is expelled (about ten minutes). Then the solution is cooled, diluted with water to approximately 400 c.c., and the chromium is determined by titration with standard ferrous ammonium sulphate and standard potassium permanganate. Ferrous ammonium sulphate solution is added until chromium is reduced (50 c.c. from pipette). Standard potassium permangate solution is added from a burette until the solution assumes a pink color which does not fade upon continued stirring. If vanadium is present the pink color will slowly fade, owing to the slow reoxidation of the vanadium. When the vanadium is completely oxidized, however, a pink color lasting one minute is obtained, which is the end point.

The per cent of chromium is obtained by conducting a blank titration on the ferrous ammonium sulphate solution, the same volume of water being used. The difference in cubic centimeters between the volumes of permanganate solution required in the actual determinations represents the volume of permanganate equivalent to the chromium in the steel, and is multiplied by the value of 1 c.c. of permanganate solution in terms of chromium.

VANADIUM

After the chromium has been determined, 5 c.c. of $\frac{N}{20}$ approximately — ferrous ammonium sulphate are added. The contents of the beaker are then stirred thoroughly, after which 10 c.c. of ammonium persulphate (20 per cent solution) are added, stirring continually for about one minute. Potassium permanganate (0.03922 N) is then slowly added until a pink end point that remains after one minute's stirring is obtained. Each cubic centimeter used is equivalent to 0.1 per cent vanadium when 2 grams of the sample are taken for analysis.

A blank determination should be made either on plain steel or on steel containing about the same chromium

content as the sample being analyzed. The blank obtained is equivalent to from 0.02 to 0.03 per cent vanadium and is constant. The ferrous ammonium sulphate and ammonium persulphate is sufficient to take care of vanadium as high as 0.60 per cent; for higher vanadium more of the above chemicals should be added.

SOLUTIONS FOR CHROMIUM

Potassium permanganate, 3.61 grams; water, 1000 c.c. One cubic centimeter of normal potassium permanganate equals 0.01733 gram chromium, but potassium permanganate equals 1 per cent of the chromium required to overcome the green color of chromic sulphate in solution. Therefore 0.0175 times the normality of the permanganate divided by 2 (2-gram sample taken for analysis) and multiplied by 100 gives the value of 1 c.c. of potassium permanganate in terms of chromium.

Sulphuric acid-silver nitrate mixture: Silver nitrate, 5.5 grams; water 330 c.c.; sulphuric acid (1:1), 670 c.c.

Ferrous ammonium sulphate, 19.6 grams; water, 900 c.c.; sulphuric acid (1:1), 100 c.c.

SOLUTION FOR VANADIUM

Potassium permanganate, 1.24 grams; water, 1000 c.c. One c.c. equals 0.1 per cent vanadium when 2 grams sample are taken for analysis.

Western Metallurgical Field

Improvements in Tungsten Recovery.

Several changes in the dressing of tungsten ores as practised in the Boulder, Col., region, have occurred since the publication of the articles in METALLURGICAL AND CHEMICAL ENGINEERING, Vol. XVI, pp. 559 to 565, and Vol. XVII, pp. 73 to 78.

The step generally considered most important at all mills is the prevention of sliming at the start of milling operations. While this trend was felt early in this year it at present amounts practically to a mania among the mill men, and stamps and sliming mills are being rapidly replaced by non-sliming rolls. The saving of the maximum amount of the values before fine grinding is now one of the constant endeavors of the operators of the Boulder district.

At the present several mills are contemplating a separate treatment of all middlings. The middlings are collected in bins and when a sufficient quantity of this material has accumulated it will be treated in a distinct department. This is a very wise move. Previous practice has been to return these middlings to the head of the mill and let them pass through a second time, which, as is readily seen, is a useless waste of power and capacity.

The Vasco mill has materially cut down the feed to the rag plant by a concentration on Deister tables. These tables give a 60 per cent concentrate, which is shipped directly. The management has not yet decided what to do with the middlings, but in all probability they will be collected and treated in a separate unit. Only the tailings from the Deisters go to the rag plant, enabling the company to cut down its rag plant area.

An entirely new method is used by the Tungsten Products Company. This company treats custom ores, jig concentrates, table concentrates or any other material they can purchase. The material is first very carefully graded by screening on 20, 40, 60, 80 and +150 mesh sieves of the impact type. All sized material is then treated by a three-magnet Wetherill Separator. The flux used varies somewhat, depending on the size and the nature of the product.

The material is fed to the belt by a mechanical feeder and evenly distributed by means of a rotating brush. The feed is rather thin, due principally to the small amount of available material; the plant handles only 5 tons per day. The ore then passes under the first magnet, which operates on a low amperage, and which eliminates most of the iron contained on the belt at its two poles. The amperage passing through the second magnet is about 3.5 amp. At its leading pole an iron silicate is removed, while at the other pole some of the tungsten is caught. Most of the tungsten, however, is obtained from poles of a third magnet whose amperage is 7. The tailings drop over the end of the belt and consist mainly of silica and pyrites. Between and underneath the second and third magnets are brushes which assist in removing the small quantities of tungsten retained on the belt. The concentrates obtained from this magnetic separation are of a high grade, low in magnetic iron oxide, pyrites and silica.

Half-Yearly Metal Production

During the year 1917, up to the end of June, all the copper mines and smelters in Arizona had been producing at capacity, with very little interruption other than a strike at Jerome, according to information gathered by the U. S. Geological Survey. Labor troubles developed widespread curtailment of production, and an expected record production of more than 700,000,000 lb. has been defeated, for since that time every producer in the state has been seriously curtailed, some being shut down as long as five weeks, while the Clifton-Morenci district is still idle.

During the first six months of 1917 every effort was made at Idaho mines to equal the unusual record of the year 1916. The value of the output in that year was $48,767,783, and for months after the close of the year the prices of silver, copper, and lead were decidedly higher. The shipments from the Coeur d'Alene region, which give an idea of conditions in Idaho, were maintaining the rate of the previous year, which was nearly 44,000 tons of crude ore and concentrates per month.

The silver, copper, and lead output of Nevada in 1917 will probably show an increase over the output of the previous year, but no improvement is expected in gold, the production of which has been steadily declining for the last few years, and little change will be made in the zinc output. Many old mines and prospects became productive when metal prices reached a point permitting long hauls to the railroads.

Montana mines made a large output of silver, copper, and zinc during the first six months of 1917, even if they were delayed to some extent by the severe winter and by fire in the mines at Butte. As the six months' period closed a multitude of intricate labor troubles broke out, at one time threatening a bloody reign of terror, and causing extreme losses in metal production.

The trouble in Butte was no sooner patched up than a strike broke out among the smeltermen at the Washoe plant, and at this writing the Anaconda Copper Mining Co. have closed all their operations in Montana.

The unusually severe winter of 1916-17 reduced the production of the mines of Utah so much that the State's output of all metals in the first six months of 1917 will not exceed that of 1916. Many of the mining camps were at times isolated by snowslides, which blocked the transportation of ore from Park City, Tintic, and the Cottonwood districts. Ore received at the smelters from the mines outside of Utah accumulated in the railroad yards and unloading was delayed on account of freezing in the cars. Then a prolonged shortage of coal and coke caused smelters and mines alike to be operated at reduced capacity. As a climax, a strike for an increase in wages closed for a short time one of the large smelting plants. Extensive improvements and enlargements of smelters and milling plants in the State indicate a greater production in the second half, which may offset any decrease during the first six months.

Although the receipts from Oregon at the mint and smelters at San Francisco show a falling off in output of gold for Oregon of some $75,000 for the first five months of 1917, as compared with the corresponding period of 1916, it is not an indication that the mines, as a whole, are less prosperous this year than last.

While the general mineral industry of California has shown exceptional activity for the first six months of 1917, as compared with the conditions in the first half of 1916, gold mining has been suffering a period of depression. The United States Mint at San Francisco, and local smelters and refiners, are in receipt of about the same quantity of gold and silver in the first five months of 1917 as in the corresponding period of 1916, proving that no advance in output has been made, notwithstanding the opening of new gold mines and reopening of old ones.

Power Hearing in California

The California Railroad Commission has instituted on its own motion an investigation into rates, rules and practices of the Great Western Power Company, the Sierra & San Francisco Power Company and the Pacific Gas & Electric Company as applied to the proposed plant of the Pacific Electro Metals Company. The last-named company was organized recently to build and operate a five-hundred-thousand-dollar plant for reducing and refining metals on San Francisco Bay. Complaint was made to the commission that when the power companies were asked for rates on approximately 10,000 hp. two companies quoted $36 per horsepower-year and one $40 per horse-power-year. The Pacific Electro Metals Company asserts that a rate of $15 is sufficient for this class of business.

The early examination of officials, engineers and rate experts from the three power companies produced a formidable collection of statistics. There is general agreement on the importance of the principles of rate making which are involved.

After the examination of the power company officials has been completed the commission will present the results of its study of the matter. This will be accompanied by a map showing the transmission lines of the state and suggesting means of combining them so as to cut down the cost of service, reduce the steam standby charges and conserve power resources generally.

Meanwhile construction is actively under way on the Pacific Electro Metals plant at Bay Point.

Coming Meetings and Events

American Chemical Society, Boston, Sept. 10-15.

National Safety Council, New York, Sept. 10-15, 1917.

National Exposition of Safety and Sanitation, New York, Sept. 10-15, 1917.

Third National Exposition of Chemical Industries, Grand Central Palace, New York, Sept. 24-29, 1917.

American Institute of Metals and Foundrymen's Association, Boston, week of Sept. 25 to 28, 1917.

Technical Association of the Pulp and Paper Industry.—Joint meeting with the Technical Section of the Canadian Pulp and Paper Association, Holyoke, Mass., Sept. 27 to 29, 1917.

American Electrochemical Society, autumn meeting, Pittsburgh, Oct. 3-6, 1917.

American Institute of Mining Engineers, annual meeting, St. Louis, Oct. 8-13, 1917.

American Gas Institute, Washington, D. C., Oct. 16-19, 1917.

American Society of Mechanical Engineers, New York, Dec. 26-29, 1917.

Program of Fall Meeting of American Electrochemical Society

One of the features of the Pittsburgh meeting to be held from Wednesday, Oct. 3, to Saturday, Oct. 6, will be a session devoted to the application of electrochemistry and electric furnaces to the manufacture of war supplies and munitions. Some of the members who have been taking an active part in the Advisory work in connection with National Preparedness have been asked to take part in this symposium and it is expected that it will prove one of the most interesting features of the Pittsburgh meeting. Touching as it does on the needs of our country at the present moment, it will add considerable patriotic as well as scientific interest to the meeting.

It is earnestly requested that any members who can add even a short discussion to this symposium communicate at once with the chairman of the Local Papers Committee, Mr. R. E. Zimmerman, assistant director, Research Laboratory, American Sheet & Tin Plate Company, 210 Semple Street, Pittsburgh, Pa. The general discussion will of course be open to the entire membership.

PROGRAM OF THE MEETING

Wednesday, Oct. 3.

Automobile trip from headquarters, Wm. Penn Hotel, at 1 p. m., to Oakmont Country Club, where members may spend the afternoon playing golf or enjoying each other's society.

Informal dinner at 6.30 p. m.

Meeting of Publication Committee and Board of Directors, 8.00 p. m.

Ladies are invited to participate in this trip. This will be in charge of Messrs. Hitchcock and Rodman.

Thursday, Oct. 4.

Reading and discussion of papers—headquarters, Wm. Penn Hotel, until 1 o'clock.

Complimentary luncheon.

Optional excursions during the afternoon:

1. American Zinc & Chemical Company, Langeloth, Pa. (Zinc Reduction and Sulphuric Acid.)
2. Visit to the new Research Laboratory of the Youngstown Sheet & Tube Company, Youngstown, Ohio. (This laboratory is one of the best things of its kind, having been recently finished at a cost of over $500,000.)
3. Visit to Research Laboratory of the American Sheet & Tin Plate Company, Pittsburgh, Pa.
4. Optional visits to—
   University of Pittsburgh,
   Carnegie Technical Schools,
   Carnegie Museum,
   Bureau of Mines Building (new),
   Mellon Institute of Industrial Research.

8 p. m.—Address by Mr. Alex Dow, President of the Detroit Edison Company, on "Production of Steam from Coal," illustrated by lantern slides and followed by general discussion of the power problem.

This will be of special interest in view of the attention which has been given this subject on account of the shortage of water power at Niagara Falls and the consequent necessity of certain electrochemical industries in the East seeking additional sources of power. Mr. Dow is recognized as one of the foremost authorities on this subject.

9.30 p. m.—Informal reception. Music and light refreshments.

Friday, Oct. 5.

9 a. m.—Symposium: Electrochemical War Supplies.

2 p. m.—Optional exursions to:

1. Atlantic Refining Company, Pittsburgh, Pa. (Refining of Crude Oil.)
2. Owen Bottle Works (showing an extremely interesting automatic manufacturing process).
   Note.—A special car will convey members to both these plants. Messrs. Kemery and Goodale in charge.
3. Republic Chemical Company, Neville Island (Detinning of Tin Scrap). (Use of Warner Cells for Manufacture of Chlorine.)
   Note.—A special car will convey members to this plant. Messrs. Turnock and Gibson in charge.
4. Radium Laboratory, East Pittsburgh, Pa.

In addition to the above optional trips arrangements are under way for visiting a number of other plants, including:

The By-Products Coke Ovens.

Chemical Manufacturing Works, etc.

There are a large number of electric furnaces in operation in the neighborhood of Pittsburgh which it will be possible for members to visit.

Friday evening—Informal subscription dinner with a number of special features.

Saturday, Oct. 6.

All-day excursion on special train, with complimentary luncheon. The following works will be visited.

Westinghouse Electric & Manufacturing Company, East Pittsburgh.

National Tube Company, McKeesport.

Large electric furnaces at Carnegie Steel Company, Duquesne, Pa.

American Window Glass Company, Arnold, Pa.

New York Meeting of National Safety Council

The Sixth Annual Safety Congress of the National Safety Council will be held in New York City, Tuesday, Sept. 11, to Friday, Sept. 14, inclusive, with headquarters at the Hotel Astor. In connection with the congress the National Exposition of Safety and Sanitation will be held at the Grand Central Palace during the same week.

A glance through the forty-page program of the congress shows the enormous amount of interesting and important work that is to be taken up during the general sessions and the various sectional meetings. The Chemical Section meets on Wednesday, Sept. 12. The Iron and Steel Section meets on Wednesday, Thursday and Friday. The Paper and Pulp Section meets on Thursday and Friday. The program of the Chemical Section is as follows:

CHEMICAL SECTIONAL MEETING
Wednesday, Sept. 12, 1917
2 to 5 P. M.
Chairman, J. R. de la Torre Bueno
General Chemical Co., 25 Broad Street, New York City
Vice Chairman, I. V. Kepner
Pennsylvania Salt Mfg. Co., Widener Blg., Philadelphia, Pa.
Secretary, R. A. Medina
Independence Bureau, Philadelphia, Pa.

Program

1. Report of Chairman.
2. Report of Secretary.
3. Reports of Committees.
4. Appointment of Nominating Committee.
5. Addresses.
   (1) "Manhood Conservation in Munitions and Chemical Plants in Canada"—Dr. John S. Bates, Imperial Munitions Board of Canada, Montreal, Can.
   (2) "General Dangers from Strong and Mixed Acids, from the Safety Man's Point of View"—Mr. R. G. Griswold, E. I. DuPont De Nemours Co., City Point, Va.
   (3) "The Hazards of Caustic Soda Manufacture and Use"—Mr. E. Fiesinger, Semet-Solvay Co., Syracuse, N. Y.
   (4) "Prevention and Treatment of Cases of Poisoning by Tri-Nitro Toluol and Picric Acid"—Dr. R. W. Chaffee, Staff Physician, Semet-Solvay Co., Syracuse, N. Y.
   (5) "Packing and Plant Handling of Hazardous Chemicals, with Special Reference to Returned Empties"—Mr. N. A. Laury, Supt., Camden and Easton Works, General Chemical Co., Camden, N. J.
6. Report of Nominating Committee and Election of Officers.

N. B.—Twenty minutes will be allowed for each of the addresses and discussions.

This program has been arranged with the end in view of making it practical and applicable to present-day conditions.

Some parts of it may seem commonplace to men who have made a life-long study of the safety problems of the chemical industry. It has been found, however, that many of those present at the meetings are representatives of other industries who are users of heavy chemicals and acids in their processes, and who urgently need some light to help them solve safety problems. At this particular moment, however, there are large numbers of people working in chemical lines owing to the enormous growth of the industry in this country because of the war.

Exhibitors at the Exposition

Following will be found a list of exhibitors complete to date at the Third National Exposition of Chemical Industries, to be held in the Grand Central Palace in New York during the week of September 24. We have already published the tentative general program and in our next issue will have some interesting announcements to make in regard to the motion picture program which alone will be well worth a visit to see. The exhibitors to date follow:

Abbe Engineering Co.
Abbe, Paul O.
Ackerman Co., H. R., Inc.
Ainsworth & Sons, Wm.
Alberene Stone Co.
Amalgamated Dye & Chemical Co.
American Aniline Products, Inc.
American Bitumastic Enamels Co.
American Blaugas Corporation
American Chemical Mfg. Co., Inc.
American Chemical Society—Alabama Section
American Coal & By-Products Coke Co.
American Cyanamid Co.
American La France Fire Engine Co., Inc.
American Metal Co., Ltd.
American Synthetic Dyes, Inc.
American Synthetic Color Co.
American Steel Package Co.
American Transformer Co.
Anaconda Copper Mining Co.
Angel H. Reeve & Co., Inc.
Anti-Hydro Waterproofing Co.
Apex Chemical Co., Inc.
Arkell Safety Bag Co.
Armstrong Cork Co.
Arnold Hoffman & Co.

Badger, E. B., & Sons Co.
Baker, J. T., Chem. Co.
Barber Asphalt Pav. Co., Inc.
Barrett Company, The.
Bausch & Lomb Optical Co.
Beach-Russ Co.
Beckers, Wm., Aniline & Chem. Co.
Benzol Products Co.
Bethlehem Foundry & Mch. Co.
Blakiston's, P., Son & Co.
Bloede Co., Victor G.
Boyer Oil Co.
Brassard Co., Inc., The
Bristol Co., The
Brown Instrument Co., The
Buffalo Fdry. & Machine Co.
Butterworth-Judson Corporation

Calco Chemical Co.
Campbell, John, & Co.
Canadian Chemical Journal
Carborundum Company, The
Carolina, Clinchfield & Ohio Ry.
Carrier Engineering Corp.
Castner Electrolytic Alkali Works
Celite Products Co.
Celluloid-Zapon Co.
Central Dyestuff & Chem. Co.
Central of Georgia Railway
Central Scientific Co.
Chemical Catalog Co.
Chemical Co. of America, Inc.
Chemical Construction Co.
Chemical Engineer, The
Chemical Pump & Valve Co.
Chile Copper Co.
Chile Exploration Co.
Chromos Chemical Co.
Clark's Iron Foundry
Clenzall Machines Co. of America
Condensite Co. of America
Consolidated Color & Chem. Co.
Consolidated Gas, Elec. Light & Power Co.
Contact Process Co.
Coors Chem. Porcelain Co.
Corning Glass Works
Corn Products Ref. Co.
Crandall Pettee Co.
Crane Co.
Crescent Color & Chemical Works, Inc.

Day Co., J. H.
De Laval Separator Co.
Denver Fire Clay Co.
Detroit Chemical Works
Detroit Range Boiler Co.
Devine Co., J. P.
Diamond State Fibre Co.
Dorr Company, The
Dow Chemical Co., The
Downingtown Mfg. Co.
Draeger Oxygene Apparatus Co.
Draper Manufacturing Co., The
DuPont, E. I., de Nemours & Co.
Duriron Castings Co.
Dye Products Chemical Co., Inc.

Edison, Thomas A., Inc.
Eimer & Amend
Electro Bleaching Gas Co.
Electron Chemical Co.
Electrolytic Zinc Co., Inc.
Electrolytic Eng. Corp.
Elmore, G. H.
Elyria Enameled Products Co.
Empire Chemical Co.
Equithern Control Corp.
Everlasting Valve Company

Fleisher & Co., W. L., Inc.
Foote Mineral Co., Inc.
Foundation Co., The
Foxboro Co., The
Franco-Swiss Dyes, Inc.
Freeport Sulphur Co.
Fuller Engineering Co.

Garrigues, Chas. F., Co.
Geisenheimer & Co.
General Bakelite Co.
General Chemical Co.
General Ceramics Co.
General Electric Co.
General Filtration Co., Inc.
Glens Falls Mch. Works
Gordon Engineering Corp.
Goulds Mfg. Co., The
Greiner Emil Co., The
Guernsey Earthenware Co.

Hanovia Chem. & Mfg. Co.
Hardinge-Conical Mill Co.
Harrison Safety Boiler Works
Hayward & Co., S. F.
Hellenic Chem. & Color Co.
Hemingway, Frank, Inc.
Hepworth Co., S. S.
Hercules Eng. Corp.
Herold China & Pottery Co.
Hood, B., Mifflin Brick Co.
Hooker Electrochemical Co.
Hoskins Mfg. Co.
Houston Real Estate & Loan Co.
Huff Electrostatic Sep. Co.
Hunter Dry Kiln Co.
Huyck, F. C., & Sons

Imperial Color Works, Inc.
Imperial Dyewood Co., Inc.
Independent Chemical Co.
Industrial Filtration Corp.
International Equipment Co.
International Glass Co.

Janney Steinmetz & Co.
Jewell Polar Co.

Kalbfleisch Corp., The
Kelly Filter Press Co.
Kewaunee Mfg. Co.
Keystone Fibre Products Co., Inc
Keystone Minerals Co.
King Chemical Co.
Klett Mfg. Co., Inc.
Klipstein, A., & Co.
Knoxville Board of Commerce
Koppers Co., H.

Laboratory Supply Co., The
Lead Lined Iron Pipe Co.
Leeds & Northrup Co.
Lehigh Car Wheel & Axle Works
Lehigh Foundry Co., The
Lehigh Stoker Co., The
Life Saving Devices Co.
Little, Arthur D., Inc.
Lummus, Walter E., Co., The
Lungwitz, Emil E.

Zaremba Company

Annual Meeting of Society of Chemical Industry

The annual meeting of the Society of Chemical Industry was held at Birmingham, England, at the University, during the week of July 16, 1917. Dr. Charles Carpenter presided and about 200 were present. The Council forwarded to the Board of Trade the following resolution:

In view of the impossibility of deriving benefits from patents during the war, the Council of Safety of Chemical Industry is of opinion that the payment of the annual fees upon patents should be suspended during the war, and that the duration of British patents should be extended for the same period.

The president in his address made a special plea for a greater education of the people in chemistry and engineering.

Special subjects which are being taken up by committees of the society are, refractories, industrial alcohol, and sugar. The following list of papers which were read show the trend of applied chemistry in England at the present time:

Some Observations on the Texture of Fire Clays. By W. E. King.

Chemical Porcelain. By Henry Watkins.

Sands Used in Metallurgical Practice and in Glass Manufacture. By P. G. H. Boswell.

Industrial Fuel from Gasworks. By E. W. Smith.

The Calorific Value of Industrial Gaseous Fuel. By W. J. Pickering.

Some Sources of Benzene and Toluene for High Explosives. By T. F. E. Rhead.

The Synthesis of Ammonia and its Oxidation to Nitric Acid. By E. B. Maxted.

Manufacture of Synthetic Nitrates by Electric Power. By E. Kilburn Scott.

Gasoline Specifications for Government Use

The method adopted by the Bureau of Mines in preparing specifications for Federal purchases of gasoline in the District of Columbia was briefly described in the *Engineering News-Record*, as follows:

Samples of the various types of motor gasoline sold in the district were analyzed. A specification was then written which represented the average product already on the market, previous experience having indicated this to be satisfactory. The procedure adopted made it possible for the Federal Departments to obtain motor fuel suitable for the motors in use, and equal in quality to that dispensed to private users. While this method of determining specifications is not absolutely scientific, it is practical and gave the following specifications:

COLOR

Requirement—Water white.

Method of Determination—Inspection of column in 4-oz. samples bottles.

ACIDITY

Requirement—Total absence.

Method of Determination—Ten cubic centimeters of the gasoline is to be shaken thoroughly with 5 c.c. of distilled water. The aqueous extract must not color blue litmus paper pink.

VOLATILITY

Requirement—The gasoline shall, when distilled by the method described in Technical Paper No. 166 of the Bureau of Mines, meet the following requirements:

A. The temperature read on the thermometer when 20 per cent has distilled shall not be below 70 deg. C. (158 deg. Fahr.), nor above whatever limit is fixed after due consideration of conditions of use.

B. The temperature read when 90 per cent has distilled shall not be above another limit similarly chosen.

C. The temperature read when 50 per cent has distilled shall not be higher than a mark halfway between the 20 per cent and the 90 per cent limit.

D. The dry point shall not exceed the actual 90 per cent reading by more than 55 deg. C. (99 deg. Fahr.).

Tolerance—If either the 20 per cent or the 90 per cent temperature mark is above the required limit by an amount not exceeding 10 deg. C. (18 deg. Fahr.), the gasoline may be considered acceptable if the sum of the two temperatures read for the 20 per cent and the 90 per cent marks does not exceed the adopted limit.

Output of American Dyestuff Industry

In an attempt to secure more complete and detailed returns of the dye industry in the United States on June 6, the Bureau of Foreign and Domestic Commerce sent out return blanks to all manufacturers of dyestuffs known to the bureau, and the returns just compiled are from practically all. More than 100 forms were returned, and the data includes the entire industry with the exception of a few minor firms and of new business organizations about to enter upon manufacturing.

From figures submitted by the manufacturers the following totals of monthly production for the current year have been compiled:

	Firms Making Returns	Pounds
Crudes	22	.....
Benzol, toluol and some xylol and phenol (Gals.)	..	1,240,350
Benzol, toluol, natural and synthetic phenol, cresol, naphthalene, anthracene and some xylol, cumol and amylene	..	6,181,600
Intermediates	40	10,420,600
Artificial colors	46	5,000,000
Vegetable dyestuffs and extracts (including some tanning extracts not stated separately)	13	8,183,500

These returns are nearly complete. They are fairly representative of the industry as a whole, though faulty from a statistical standpoint since no returns were received from several minor firms so recently established as to be unable or unwilling to go into details of product and output, but whose combined production for the remainder of the calendar year would constitute only a small percentage of the whole. In some instances the figures for benzol are in excess of the amount used in the production of synthetic phenol.

Manufacturers are now producing toluidines, resorcin, xylidine, dianisidine, naphthylamine, diphenylamine, tolidine, benzidine, benzaldehyde, benzylchloride, nitrobenzol, nitrotoluol, H-acid, phthalic, metanilic, sulfanilic and naphthionic acids, naphtholsulfo acids, naphthylaminsulfo acids and amidonaphtholsulfo acids, Schaeffer's salt, paranitraniline, dimethylaniline and others.

The current monthly production of forty-six manufacturers of finished dyes is at the rate of 5,000,000 lb., or 60,000,000 lb. annually, individual outputs ranging from 600 to over 2,000,000 lb. each. This does not include any estimate from one plant of the first magnitude whose entrance into the industry has just been announced to the trade, or a score of smaller projects organized but not yet in full operation. The total shown includes only the figures given by the factories of actual

production for the current calendar year, and makes no allowance for many plants now in course of construction, which will soon be producing colors on a commercial scale, nor for the output of many dyes still in the experimental stage. These facts leave no doubt that our present annual domestic output greatly exceeds in quantity the entire consumption of artificial colors in the United States during the year 1914, estimated at 60,000,000 lb., and is probably equivalent to the current annual consumption, which is considerably in excess of that for 1914.

Coal-tar dyes in a variety of colors suitable for leather, textiles, straw, paper, inks, stains, pigments, varnishes, waxes, feathers, furs, and for many other purposes are now regularly obtainable from domestic sources. Several manufacturers carry full lines of direct, acid, basic, chrome, oil and sulphur colors, while others confine their efforts to improving and extending their output of particular groups. Prominent among the colors produced are nigrosines, indulines, triphenylmethane dyes, safranines, eosines, chrysoidines, thodamines, rosanilines, direct fast reds, browns and yellows for cotton, fast chrome colors for wool, Sudan colors, basic violets, synthetic indigo and indigotines, alkali blues for the silk and woolen industries and also for the lithographic trade, metanil yellow, methyl violet, methylene blue, benzopurpurine, benzo sky blue, primuline, naphthol green, rose bengale, gallocyanine, and special chrome and khaki colors.

Considerable attention is being given by about a dozen firms to developing as rapidly as the requisite intermediates are available the triphenyl-methane dyes, particularly fuchsine, methyl violet, methylene blue, magenta, and malachite green. Their output of many of these colors was not separately stated by some of the factories. The itemized figures given by only a few of the plants, however, show a monthly production of this series of colors amounting to 62,200 lb. Of this quantity 18,200 lb. represent methyl violet and 13,450 lb. methylene blue. Two manufacturers specialize on the needed intermediates for these dyes.

There is a largely increased production and variety of reds, yellows, and scarlets, prominent among them being parareds for the printing trade, lithol red R, paramagenta, croceines, fast red Bordeaux for wool, acid reds and scarlets, wool scarlet, Biebrich scarlet, chrome yellow, metanil yellow, chrome orange, and brilliant orange. A wide range of fast reds, blues, greens, yellows, blacks, and grays for cotton is also available.

Colors now produced on a commercial scale that were not made in this country until recently are alizarin blues, browns, and yellows for calico printing, and for wool; paracolors for lakes or pigments, vat dyes (sometimes called indigoids) for cotton shirtings and ginghams, synthetic indigo, rhodamine, patent blue, and Biebrich scarlet.

Present production and new developments contemplated include blacks and greens in natural colors for calico printers, a special logwood blue, special mordants for dyeing new shades in direct cotton colors, khaki dyes, cutch, archil, and logwood extracts, and cudbear powdered, orange, and lemon flavines, Osage orange in a variety of shades, American sumac extract, indigotin, and natural indigo shades. It is stated by several plants that their output depends on the domestic demand, ample facilities being available for a largely increased production at any time. Some operate at half capacity while others are running 24 hours a day.

One firm is making sulphur brown (not a coal-tar product) on an extensive scale, while another company is producing mineral colors in standard shades for wool.

Soluble Prussian blue, Chinese blue, pigment brown, lakes in all the principal colors, paratoners, dry colors, and dyes for lake makers are specialties handled by different manufacturers.

The urgent demand for photographic developers since the war began has greatly stimulated the production of hydroquinone, p.-amido-phenol, metol, amidol, and reducin. Single firms report monthly outputs of 1000 to 15,000 lb. each of hydroquinone.

Manufacturers of coal-tar by-products are also marketing quantities of salicylic acid and its derivatives—particularly acetyl-salicylic acid (aspirin)—phenacetine, acetphenetidin, acetanilide, and other medicinals.

One maker of intermediates is producing the synthetic perfumes nerolin and bromelia. Another firm includes vanillin, used in flavoring extracts, in its list of products, and also saccharin.

The most striking feature brought out on the forms filled in by the dyestuff manufacturers is the marvelous growth of the industry and the plans in process of formation for its continued expansion in both domestic and foreign fields.

Announcement has been received of the entrance into the dyestuff industry of the leading company manufacturing explosives, fully equipped with a chemical and engineering staff, plant, and laboratory facilities, and an adequate commercial organization to meet the demand for colors on a vast scale. Other new plants in process of construction or to begin operations before 1918 are two for coal-tar crudes, one for anthracene, one for glacial acetic acid, four new buildings for aniline dyes, one for chrysoidine and methylene blue, one for nigrosine, induline and magenta, and one for nigrosine only. A producer of direct, acid, and chrome colors expects to double his present output of nearly half a million pounds annually inside of 12 months. One plant making methylene dyes is planning to double its capacity, two others making aniline colors will also double their capacity shortly, one manufacturer expected to have patent blue and fuchsine on the market after July, one of the larger corporations is now making auramine and lanafuchsine on a small scale and installing equipment for their increased output, and another contemplates the manufacture of primuline in considerable quantity. A producer of high-grade colors for silk is enlarging his factory and contemplates the early production of safranine and a suitable plant for the extensive manufacture of aniline dyes.

Dyes and dyestuffs exported from the United States during the fiscal year ending June 30, 1917, were valued at $11,710,887, as compared with $5,102,002 for 1916. Beginning with July 1, 1917, the classification for monthly statements of exports will include under dyes and dyestuffs the subdivisions, aniline dyes, logwood extract and all other shown separately.

The capital stock of the ninety companies reporting amounts to a total of $158,913,650. This, of course, does not represent actual money invested, as many concerns merely incorporate with a large capital to allow for expansion. The actual amount of paid in capital and capital invested in plants is not known.

The Electrolysis of Fused Cerium Chloride[1]

By M. deKay Thompson

That cerium can be produced by the electrolysis of fused cerium chloride is a well known fact, and it is also known that this is the method of manufacturing the cerium imported into this country before the outbreak of the war. That the process is workable is therefore well established, but to carry it out on a commercial scale with simple apparatus requires the knowledge of a number of details which have never been published. It was the object of the following work to find the proper conditions for the manufacture of cerium and to produce enough to demonstrate that this end had been reached.

The nearest approach to what was desired is the work of Hirsh.[2] A review of previous investigations on this subject is given in this article, and may therefore be omitted here. Hirsh made in all only about 1.5 kilograms of metal, and had to dehydrate his cerium chloride in an atmosphere of hydrochloric acid to prevent decomposition, and even then the baths tended to become pasty after a few hours electrolysis. Certainly no one would consider these results a sufficient preparation for starting upon the manufacture of cerium.

There are a number of difficulties that may be encountered in attempting to electrolyze fused salts. The principal ones are the following:

1. The anode effect[3] which has the appearance of being a sudden insulation of the anode from the melted bath by a film of gas. This prevents the current from passing unless a high voltage is applied, and when this is done a high temperature is produced, with consequent vaporization of the salt. One method of overcoming this is to design the apparatus so as to have a lower current density at the anodes.

2. The bath becomes viscous, and will not conduct properly. This was the cause of much trouble to Hall while he was working out the process for aluminium.

3. The metal does not collect in a solid nugget, but remains distributed through the salt in small particles.

4. The metal dissolves in the fused bath, diffuses to the anode and recombines, as in the case of sodium or potassium hydrate.

5. The salt decomposes during dehydration or during electrolysis. This is especially apt to occur with chlorides.

In the following work no trouble was experienced with the anode effect; it appeared only once or twice during the whole course of the experimentation. The principal difficulty was that on electrolysis the salt turned into a black mass, which on cooling smelt like carbide, and which showed no sign of metal to the naked eye. This may be formed even when the electrolysis is to all appearances proceeding properly. Some decomposition took place during dehydration, but this was easily rectified during the electrolysis, as will be explained.

The first raw material was obtained in the form of the hydrated cerium chloride, somewhat of the appearance of brown sugar. Later, over 300 lb. of cerium oxide were obtained from the Welsbach company, which was converted to the chloride by dissolving in strong hydrochloric acid in earthenware crocks and evaporating to dryness in enamel lined preserving kettles. It was then broken out of the kettle with a cold chisel and kept in air-tight jars. The dehydrated cake was about 1.5 cm. thick; if thicker than this, there was difficulty in dehydrating the top without burning the bottom of the kettle.

The following data were obtained: 35 kg. of cerium oxide and 102 kg. of strong hydrochloric acid made 45.4 kg. of anhydrous cerium chloride, from which 22.7 kg. of metal can be made. The metal was of course impure cerium, containing other rare earth metals.

The method employed for the estimation of cerium was to precipitate the cerium by alkali hydrate, filter, wash free from chloride, dissolve in sulfuric acid, and reduce to cerous sulfate with hydrogen peroxide. Permanganate was then added till the excess of peroxide was destroyed, as shown by the end point. The cerous sulfate was then oxidized with an excess of potassium ferri-cyanide and the ferro-cyanide produced was titrated with permanganate.[4]

The first supply of cerium chloride was found to be 52 per cent pure. A 10-lb. sample of cerium oxide obtained at an earlier date from the Wellsbach company, and which could be put into solution only by first converting it into the carbide[5], grinding very fine, and dissolving in hydrochloric acid, was 64.5 per cent pure.

The source of electricity was a 25-kw. direct-current motor generator, in which the voltage could be varied continuously from 10 to 35 volts.

From some of the writer's previous work on cerium chloride electrolysis, and from the description of the difficulties of others, it was believed that one cause of the bath becoming pasty was the formation of carbide by the action of the fused bath on the graphite anode. An attempt was therefore made to use a magnetite anode. The magnetite was fused in a graphite tube by forming an arc between the bottom of the tube and a smaller carbon rod which projected into the tube, and feeding in crushed magnetite. As the magnetite fused, the rod was gradually drawn out. A porous clay pot was used of 7 cm. inside diameter and 7.6 cm. high. An iron rod 0.9 cm. in diameter was used as cathode and was insulated from the fused bath by a porcelain tube, except at the end, which was bent at right angles to bring it under the anode. The electrolysis lasted for three hours at 60 amp. and 13 volts. Red fumes were given off, showing that chlorine displaced oxygen from magnetite with the formation of ferric chloride. Very little metal was found, and the fused salt had turned into the black substance described above having a characteristic carbide smell, and which reacts with water, which cerium carbide does not. This experiment therefore showed that the carbon anode is not the cause of the fused bath becoming pasty. If this black material is held up to a rapidly rotating emery wheel it gives off sparks like metallic cerium, and very small bright surfaces are visible. It therefore seems probable that this black material is cerium chloride with very finely divided cerium distributed through it.

A number of runs were then made in Denver clay crucibles 20 cm. high, and with a cathode made of an iron bolt inserted through the bottom and made tight

[1]This research was carried out from January to June, 1916, in association with Professor C. L. Norton, who proposed the method of dehydrating the cerium chloride employed, and at whose suggestion the experiments in Denver clay crucibles were made.

with iron washers. Information had been received that this was the method used abroad. Some metal was produced, but the results were still not satisfactory. On one occasion the pot bumped violently, as though boiling. One important fact was first observed in these experiments, that the oxide produced by the dehydration of the chloride is regenerated into chloride by the chlorine evolved by the electrolysis. On first melting the anhydrous chloride and electrolyzing, the surface was covered with a scum, but after a few hours electrolysis the whole electrolyte became clear. Also pieces of the broken chloride which were dark brown on the surface exposed to the air during cooling, turned white when placed in the electrolyzing vessel so as to be exposed to the chlorine gas. This change in color is doubtless due to the change from oxide to chloride. During the electrolysis, after the electrolyte had gotten into good condition, the surface of the clear liquid was covered with fine bubbles of the liberated chlorine, which were prevented from escaping immediately on account of the viscosity of the fused salt.

The first satisfactory run in which a compact nugget of metal was produced was carried out in a cast iron crucible 7.5 cm. deep and 6.8 cm. inside diameter. This crucible formed the cathode. The chloride was made from the oxide by dissolving in hydrochloric acid and dehydrating in hydrochloric acid gas, though this method of dehydrating was not necessary, as later experiments showed. The anode was a graphite rod 2 cm. in diameter. Contact with the iron crucible cathode was made by imbedding it in crushed gas-carbon contained in a larger iron pot to which a cable was connected. A current of 90 amp. at 14 volts was passed until the number of ampere hours was 882. The material was 32 per cent pure. A nugget weighing 310 grams was obtained at a current efficiency of 21 per cent. In this experiment the right combination of current, voltage, and distance between electrodes had been found to cause a large amount of the deposited cerium to fuse together. This is doubtless due to the temperature being within certain limits: high enough to melt the cerium and low enough to prevent the formation of the black material. Whether or not this is the true explanation of the success, the proper conditions for the production of cerium were found and the next step was to try to get the same conditions on a larger scale.

For this purpose a cylindrical cast iron pot, 22 cm. in diameter and of about the same depth was taken as cathode. Contact was made as in the case of the preceding run with the smaller crucible. The anode was a graphite rod 5 cm. in diameter. The chloride in all following experiments was made from oxide and was dehydrated in kettles as stated above, either with gas or electric hot plates. The experiment was started at 1.45 with 400 amp. and 13 volts. The chloride was fed in until it was within 4 cm. of the top of the pot, and at 3 p. m. the current was increased to 600 amp. At 3.20 the bath showed signs of becoming viscous. The whole bath had turned black and the escaping gas blew large bubbles of this black substance which solidified in thin crusts. The evident explanation of this was that the temperature was too high. At 3.30 the anode was lowered so as to make contact with the cathode when cold and the current was shut off. The following day a current of 300 amp. at 11 to 13 volts was passed from 11.15 to 4.30. By this time the bath had regenerated itself and was in good working order. The third day the electrolysis was continued with 300 amp. from 11.30 to 5.30 and the fourth day from 10.45 to 6.30. The yield was 3.03 kg. of metal in one large nugget and two smaller ones. The total ampere hours were 5800, and the current efficiency 30 per cent. About 1300 ampere hours were used inefficiently on account of the bath getting into bad condition by overheating. If this is not counted it brings up the current efficiency to 40 per cent.

A longer test was next made. The same size iron pot was used, and a 5-cm. graphite anode. The run was started 11.30 A. M., April 21, and lasted till 5.45 P. M. of the following day, without interruption. The current was about 300 amp. at 10 to 12 volts. The anode was kept about 1.7 cm. from the cathode, and the fused chloride was about 3.2 cm. deep. As the metal built up from below more solid chloride was added and the anode was gradually withdrawn until the pot was full. The run was started by melting some chloride in a Dixon graphite crucible and pouring it into the pre-heated iron pot. The anode was also pre-heated. The results were:

Chloride fed into pot	6.37 Kg
Metal obtained	3. Kg
Ampere hours	8700.
Current efficiency	20 per cent

A run was next made under the same conditions as in that just described except that the electrodes were brought so close together that only 5 to 6 volts were required to pass 300 amp. The smell of hydrochloric acid was strong during this run. Practically no metal was produced, but in its place appeared the black material described above. This experiment showed the electrodes must be kept a certain distance apart.

A run was then made with two pots connected in parallel, which lasted continuously from 11 a. m., May 26 to 11 a. m., May 27. The average current was 230 amp. per pot. The following table gives the results:

	No. 1	No. 2
Ampere hours	5500	4530
Kilograms of metal	2.37	1.87
Current efficiency	25 per cent	24 per cent

It may also be interesting to give the record of this experiment in full, showing the small amount of attention required. This is shown in table No. 1 on the next page.

In the next experiment four 5-cm. graphite anodes were used and the cathode was a cylindrical iron pot 20.5 cm. in diameter. Contact was made at the flanged top by means of two iron strips bolted to the flange on opposite sides of the pot. Some chloride was melted in the pot by a gas burner, and when the pre-heated anodes were immersed the electrolysis started immediately. The run lasted 5.25 hours with an average of 710 amp. and 8.5 volts, and produced 960 grams of metal at a current efficiency of 14.5 per cent.

In the next runs iron plumbers' pots, used for melting lead, were used. These were 21.5 cm. in diameter at the top and somewhat smaller at the bottom. Contact was made by bolting an iron strip to the bottom of the pot by a bolt put through a hole in the bottom. Four 5-cm. anodes were used. The current varied from 600 to 800 amp. at about 9 volts and the run lasted for six days, allowing it to cool over night. The electrolysis was started in the morning by heating the pot with a large blast lamp. The results were:

Ampere hours	15,200
Theoretical yield	23.8 Kg.
Actual yield	7.8 Kg.
Current efficiency	30 per cent

Another similar run on two successive days gave 1.03 kg. metal at 20 per cent current efficiency.

Finally a run with two pots with four 5-cm. anodes each lasted from 11 a. m. to 7.45 p. m. and from 9.30 a. m. to 9.10 p. m. of the following day. The current through each pot was about 500 amp. at 10 volts. The results were:

	No. 1	No. 2
Metal obtained	4.75	5.48
Ampere hours	8940	10,000
Current efficiency	30 per cent	31 per cent
Chloride fed in	21.3 Kg.	23.9 Kg.
Cloride left undecomposed	11.5 Kg.	15.2 Kg.
Kilowatt hours	94.1	105
Kilowatt hrs. per Kg metal	19.8	19.2

During the course of these experiments 34 kg. (75 lb.) of metal were produced, and after finding the proper conditions as regards current, volts, and distance between anode and cathode, the electrolysis always proceeded without any difficulty. The directions for carrying out the electrolysis are:

The electrolysis is best started by melting a little chloride in the iron electrolyzing vessel or in a Dixon graphite crucible from which it is poured into the electrolyzing vessel. The anodes should be hot to prevent the salt from freezing around them and insulating the current, when first immersed. The fused chloride should be about 2.5 cm. deep, and the anode should dip into it 1.7 cm. The voltage between anode and cathode should be about 10, and the current for a pot with one 5-cm. anode will then be between 250 and 300 amp. If more anodes are grouped together, the current carried by each should be somewhat less. The pots should not be heat-insulated. As the metal builds up, the anode is raised and chloride is added, either in solid lumps or fused; it interferes less with the electrolysis to add fused chloride. The cerium could be poured directly from the electrolyzing vessel, but in these experiments it was allowed to cool, the pot was broken open, and the metal separated from the chloride. This was remelted under sodium chloride and cast into bars in Acheson graphite molds.

The metal is always surrounded with the black material described above. This can be recovered for another electrolysis by dissolving in hydrochloric acid and evaporating to dryness.

2.30	260	11.1		6.30			Rounded end of anode sawed off.
7.25	230	10.7	Chloride added.				
9.40	320	10.9	Chloride added. Anode eaten to a point, and therefore sawed off.	6.45			Chloride added.
				8.45			Pot full. Shut down.
11			Pot full; shut down.				

Sulphuric Acid from Blende*

By H. M. Ridge

SOURCE OF ZINC SULPHIDES

Spelter was formerly made only from calamine, which is the carbonate of zinc, but as the world's supply of this mineral is limited it became necessary, particularly about the middle of the last century, to use zinc sulphide ore, the demand for which increased very rapidly.

The main source of spelter to-day is zinc blende. When pure this consists of zinc sulphide with 67 per cent zinc and 33 per cent sulphur and is a white, transparent mineral. The pure mineral is rarely found; zinc blende is generally black or brown and contains several per cent of iron as amorphous FeS, and frequently also some manganese. In consequence of impurities, the sulphur content is usually less than the above-mentioned figure, but if pyrites, FeS_2, is present, the sulphur assay rises.

In the ore deposits zinc blende is usually associated with galena and occasionally with copper pyrites, but it is found with most sulphide ores. No particular kind of gangue predominates; in addition to quartz, calcite, strontianite, magnesite, ankerite, siderite, barytes, and fluorspar are frequently present. Quartz and calcite are lighter than blende, barytes is heavier; the differences in specific gravity are sufficient to allow of separation by ordinary wet methods of concentration. If fluorspar is present wet concentration should be carried out carefully because it is desirable to remove fluorine, as far as possible. Siderite and ankerite have been taken out efficiently on the Continent on magnetic separators after a preliminary flash roast to form magnetic iron oxide (Fe_3O_4).

The utilization of the zinc contents of the big deposit of argentiferous zinc and lead ore at Broken Hill presented unusual difficulty, because of the presence of garnet and rhodonite of about the same specific gravity as zinc blende. This was first overcome by the use of the Wetherill electromagnetic separator with an intensely strong magnetic field. When I started the first of these plants at Broken Hill in 1899, we lifted the garnet and rhodonite out of the ore with one set of machines and then passed the residue through an even stronger field which separated the zinc blende from the galena, quartz, and calcite. This process was too expensive to be able to compete permanently and was superseded by the modern methods of flotation; to-day the whole of the zinc concentrates at Broken Hill are produced by flotation. Unfortunately, flotation methods are not, up till now, effective for separating fluorspar or carbonates from blende.

The rapidly increasing consumption of spelter threatened to cause a shortage of ore as long as calamine was the main source of supply, but improved methods of

*A paper read before the London Section, Society of Chemical Industry, June 4, 1917.

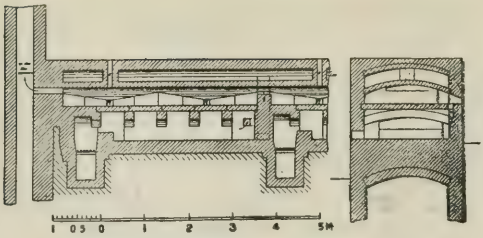

FIG. 1—HASENCLEVER FURNACE

concentration and of smelting have resulted in making available enormous resources of sulphide ore and there is an adequate supply of suitable concentrates to cope easily with all prospective demands.

I propose, in dealing with the utilization of the sulphur contents of zinc ore, to divide the subject into:

1. The extraction of the sulphur from the mineral.
2. The utilization of the sulphur.
3. Statistics and economics.

GENERAL STATEMENT OF SULPHIDE TREATMENT

The sulphur can be separated from the zinc by:

(a) Smelting with a metal having greater affinity for sulphur.

(b) Treatment with the oxide of a strong base.

(c) Heating in the presence of oxygen.

Zinc sulphide is decomposed by molten metallic iron or copper and a sulphide is formed, while metallic zinc vapor is driven off. Considerable experimental work has been done on this process, but without success, because of the expense of treating the resulting iron or copper sulphide and the possibility—when copper is used—of losing some of this metal in the process. The operation has to be carried out in a retort or crucible at a high temperature. This has some similarity to the ancient methods of brass manufacture by smelting copper ore and zinc carbonate together with carbon.

Zinc blende can be smelted with lime and carbon to form zinc, carbon monoxide, and calcium sulphide; this has been carried out in an electric furnace, but it entails a continuous fresh supply of lime, while the resulting impure sulphide of lime quickly oxidizes to sulphate and has to be run to waste.

The usual method of separating the sulphur from blende is to roast the ore with sufficient air to form zinc oxide and sulphur dioxide. The further treatment of the zinc concentrates after roasting consists in heating the zinc oxide in retorts, with suitable reduction material, to reduce the oxide and distill the reduced metallic zinc which is cooled and condensed to liquid metal.

THERMAL CONSIDERATIONS

In roasting zinc blende the sulphur is oxidized to SO_2 with a small amount of SO_3, and sufficient oxygen is also required for the formation of zinc oxide. The reaction is exothermic, but it is not possible to obtain a sweet roast without the application of heat. Sulphates are formed in roasting and these have to be decomposed, which necessitates additional heat units.

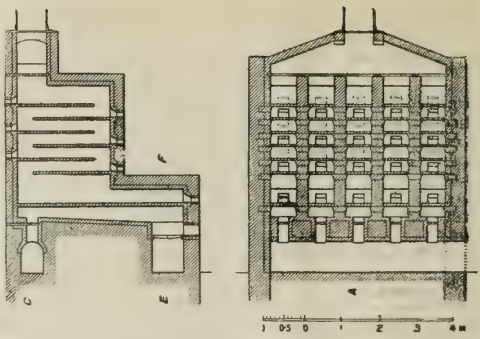

FIG. 2—IMPROVED HASENCLEVER FURNACE BUILT BY THE RHENANIA COMPANY

The heats of formation are:

$$(Zn + S) = 43{,}000$$
$$(Zn + O) = 84{,}800$$
$$(2S + O) = 69{,}260$$

If 97 kg. of zinc sulphide is oxidized completely with air containing 48 kg. of oxygen, 81 kg. of zinc oxide and 64 kg. of sulphur dioxide, equal to 22.4 cu. meters, are obtained; 200 kg. of air with 160 kg. of nitrogen will be used.

The reaction gives:

	Calories.
Formation of 81 kg. ZnS	+ 84,800
Formation of 64 kg. SO_2	+ 69,260
Total	154,060
Decomposition of 97 kg. ZnS	— 43,000
Net heat evolution	111,060

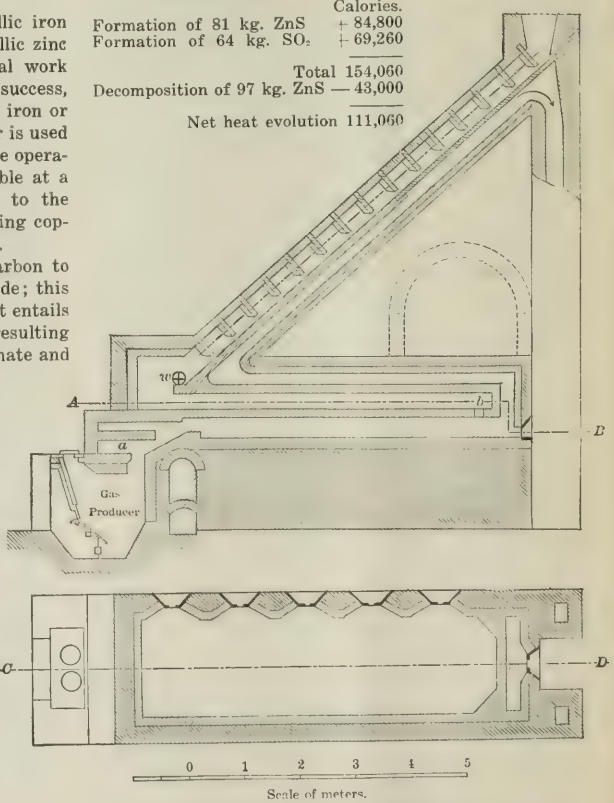

FIG. 3—HASENCLEVER & HELBIG FURNACE

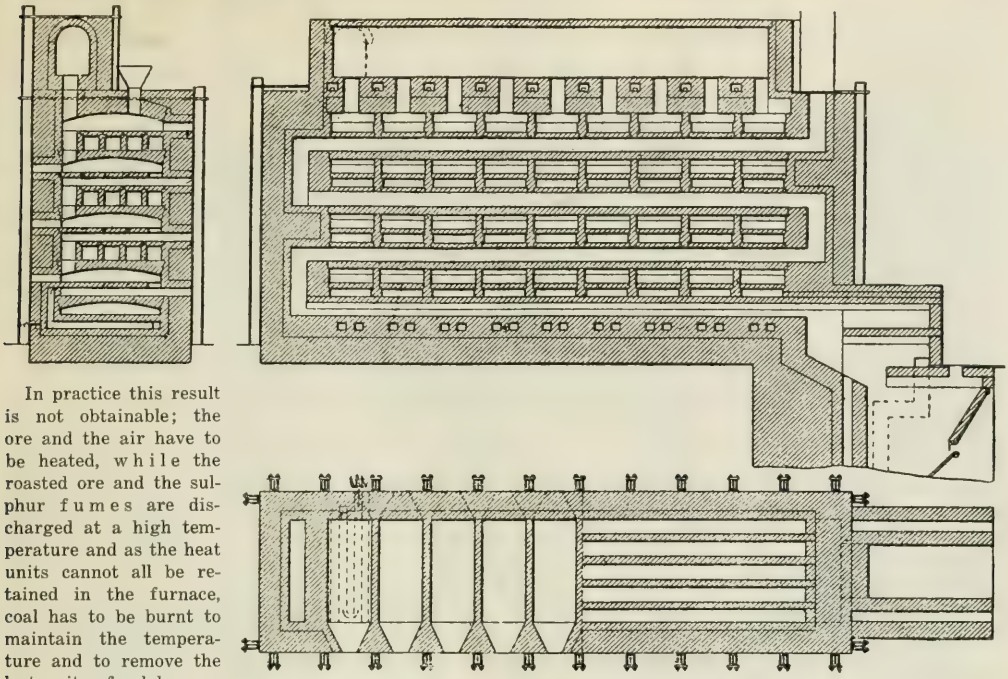

FIG. 4—RHENANIA TYPE FURNACE

In practice this result is not obtainable; the ore and the air have to be heated, while the roasted ore and the sulphur fumes are discharged at a high temperature and as the heat units cannot all be retained in the furnace, coal has to be burnt to maintain the temperature and to remove the last units of sulphur.

If the sulphur has to be used for technical purposes, the fumes must not be contaminated and diluted with fire gases. Constructional difficulties were encountered in the design of furnaces for this purpose. Muffled furnaces have to be used in which the fire gases do not come into contact with the ore, and the heat units have to be passed through firebrick in order to maintain the temperature while the last units of sulphur are being oxidized and while any sulphates which may have been formed are being decomposed.

EARLY ROASTING FURNACES

In Germany and Belgium prolonged efforts were made to prevent the emission of large quantities of sulphur fumes into the air, with the consequent destruction of vegetation in the neighborhood of the works. The first practical results were obtained about 1855 by Hasenclever, who, after a series of experiments, built a furnace at the Rhenania works, which is shown in Fig. 1. The furnace has two roasting hearths, of which only the top hearth is muffled, and after the ore has been rabbled along this hearth and has given off some of its sulphur it is dropped to the bottom hearth to complete the roasting in direct contact with the fire gases. The arches of the furnaces were too high for practical work and the fumes were low in SO_2.

In 1865 a much improved furnace was built by the Rhenania Company, and this is illustrated in Fig. 2. The results improved, but the capacity of the furnace was small and the strength of the gas continued deficient; it is worthy of note that the designer realized that it was only necessary to heat the ore during the last stages of oxidation, because there is enough heat at the commencement of roasting, but this point was overlooked for many years. The general idea of the construction of the furnace is very similar to that of "Delplace," which will be referred to later.

An effort to reduce the amount of labor was made in 1872 with the furnace shown in Fig. 3. A number of these furnaces were built at various works in Germany, but they again labored under the disadvantage that the final roast was carried out in contact with the fire gases. The furnace had 215 sq. ft. of area on the bottom direct-fired hearth, and above this a muffle of the same size was heated from above and below by the fire gases. The incline had an angle of 43 deg., which had been determined by experiment, and baffles were placed in this, so as to spread the ore in a fairly uniform thin layer. Openings were arranged for access in case of blockage. The ore traveled a total distance of about 90 ft. in the furnace. Much labor was required for breaking up lumps of ore which formed, and the furnace had to be very carefully tended. During the period when much sulphur is being given off the ore will run like water if the temperature rises too high, and if iron or lead are present in appreciable quantity the overheated ore will set hard. This frequently occurred on the incline and the design was finally discarded, because more labor was required for freeing the incline than is necessary for working a horizontal hearth. The output of the furnace per 24 hours was about 3 tons of roasted ore with a coal consumption of 15 cwt., and three men were necessary per shift, so that the output per man per shift with a 12-hour shift was only 10 cwt.

In the furnaces which were designed for part of the work to be done in the muffle and the balance in a rever-

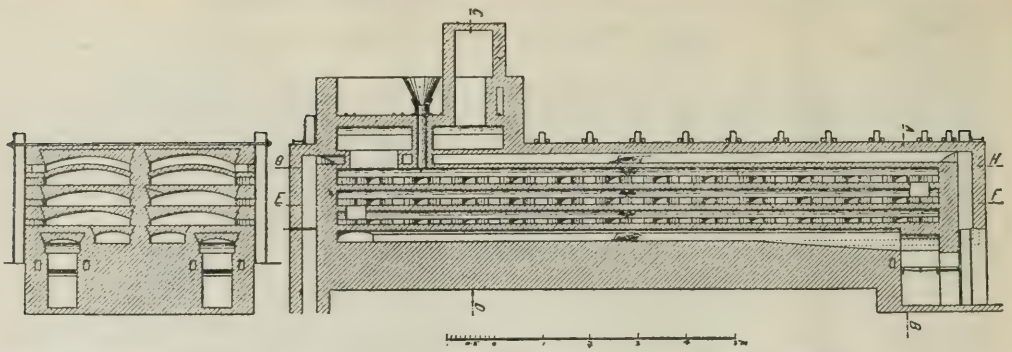

FIG. 5—MODIFIED RHENANIA TYPE FURNACE

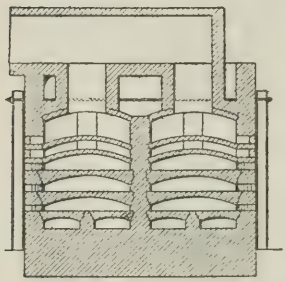


beratory, only about two-thirds of the sulphur contents were available for further use, while the remaining one-third was so diluted by the fire gases that it had to be allowed to escape into the atmosphere

In England attempts were also made to roast zinc ore in muffled furnaces, but they were not entirely satisfactory. It is remarkable that the first roasting of blende appears to have been done here. In 1758 John Champion of Bristol obtained a patent for using blende or black jack in the manufacture of brass.

RHENANIA TYPE FURNACES

The first of the furnaces of the so-called Rhenania type is shown in Fig. 4; this was built in accordance with a German patent of 1882. The furnace is provided with one fire box, and the fire gases travel four times the length of the furnace, which has nine muffles each 2 ft. 5½ in. wide, and four hearths in which the ore is rabbled by hand at right angles to the direction of the travel of the fire gases. The air for the muffles is preheated and the sulphur fumes leave the furnace with about 6 per cent SO_2. The capacity is 3 to 3½ tons of roasted ore with a coal consumption of 27 per cent; the ore remains in the furnace about 48 hours. Improvements were made in this furnace by cutting out the division walls between the muffles, so that the ore could be rabbled sideways along the hearths in the opposite direction to the travel of the fire gases; later it was found unnecessary to heat the upper parts of the furnace because the oxidation of the ore gives off sufficient heat, but before this stage was reached furnaces were built embodying almost every conceivable variation in the arrangement of the fire flues and the muffles.

Twelve years ago I still built furnaces with three superimposed muffles, the fire gases traveling beneath and above the bottom muffle, whereas it is only necessary, with proper design, to pass the fire gases under the bottom muffle. I found that in one part of the furnace the fire gas was no longer heating the ore but the ore was heating the waste gas.

For the sake of completeness I illustrate one of the later modifications of the Rhenania furnaces in Fig. 5. This furnace is 47½ ft. long by 17½ ft. wide, so that the ore travels a distance of 118 ft. along the hearths. With a 12-hour shift a total of eight men were required for the production of 6 tons of roasted ore per 24 hours. By working with eight-hour shifts only six men were required and the production per man per shift rose from 14 or 15 cwt. to 18 or 19 cwt. The coal consumption is about 25 per cent.

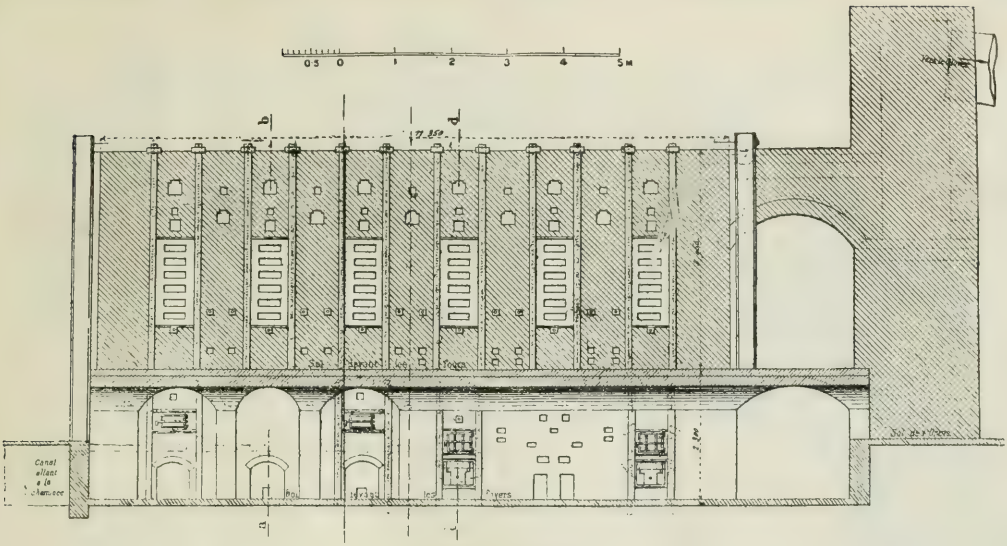
These furnaces have been generally built together in blocks of four and have been more largely used than any other type of furnace.

DELPLACE FURNACE

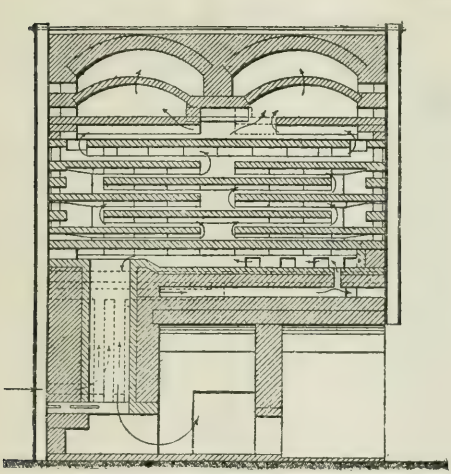
Owing to high price of fuel, "Delplace" furnaces have been largely built in Belgium since 1895. Fig. 6 shows the details of this furnace, which, with good labor, and if carefully built, gives satisfactory results. The travel of the ore on the seven superimposed hearths is only 40 ft., but the ore is exposed thoroughly to the air because the arches are low and only a thin bed of ore is maintained on each hearth. Only 16 per cent of coal is required for heating. These furnaces have been built mainly in Belgium and in France, but a few have also been erected in England and Germany. Experienced labor is required to work them satisfactorily and the men prefer to work on the Rhenania furnaces in which the ore is rabbled sideways, whereas in the Delplace type it has to be alternately pushed from and drawn toward the worker.

EARLY MECHANICAL FURNACES

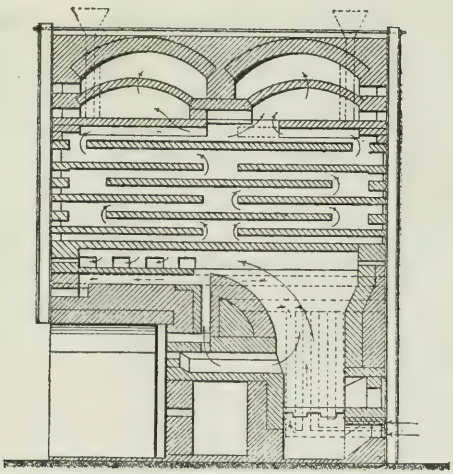
Work on zinc ore-roasting furnaces is most laborious, and even on the Continent continuous efforts have been made to replace hand labor by machinery ever since the start of the industry. The first attempt to do this was made by the Société de la Vieille Montagne, who succeeded in carrying out the first part of the operation in a furnace like a MacDougall roaster for pyrites fines —the furnace is shown in Fig. 7. The ore, after passing over three, or in some of the furnaces over four hearths, drops to two hand-rabbled hearths similar to those used in the Rhenania furnace. The mechanically stirred part had a diameter of 8 ft., but although various modifications of this furnace were tried it was not much used, mainly because of mechanical difficulties, which 40 years ago proved insuperable. The furnace is stated to have been able to treat 3½ tons of ore in 24 hours with 17 per cent of coal and ¾ hp.



Sectional Elevation



Section A-B



Section C-D

FIG. 6—DELPLACE FURNACE

In America, where hand labor was even more difficult to obtain, it was impossible to use hand furnaces. Hammond and Spence designed a furnace, which, although it is direct fired, is the forerunner of the Hegeler furnace, which has come so largely into use in the United States. In the Spence furnace the ore is rabbled along the various hearths by means of stirrers attached to long rods. This furnace shows the essential features of the Hegeler furnace, which is illustrated in Fig. 8. The Hegeler furnace, together with the end supports for the machinery, occupies a very large floor area; I understand that for the large furnace a total length of 360 ft. is required because of the runway for the stirrers at each end of the furnace; it treats 40 tons per day, with a coal consumption of about 25 to 30 per cent. The plows are drawn through the furnace by chains and, after passing through the furnace in one direction, are moved to the level of the next hearth and are then drawn through this in the opposite direction. This allows of cooling the stirring mechanism while outside the furnace. The capital outlay is large, and I have been informed that the repair bill of the furnaces working on the Continent is such that there is no appreciable saving in cost of roasting as compared with hand-rabbled furnaces. With eight-hour shifts 17 men are required per shift, so that there is no reduction in the number of men as against hand furnaces, but the men can mostly be ordinary unskilled labor together with a few mechanics.

Great things were expected from the "Merton" furnace, of which Fig. 9 illustrates the construction of a number of furnaces built in Tasmania; they have been

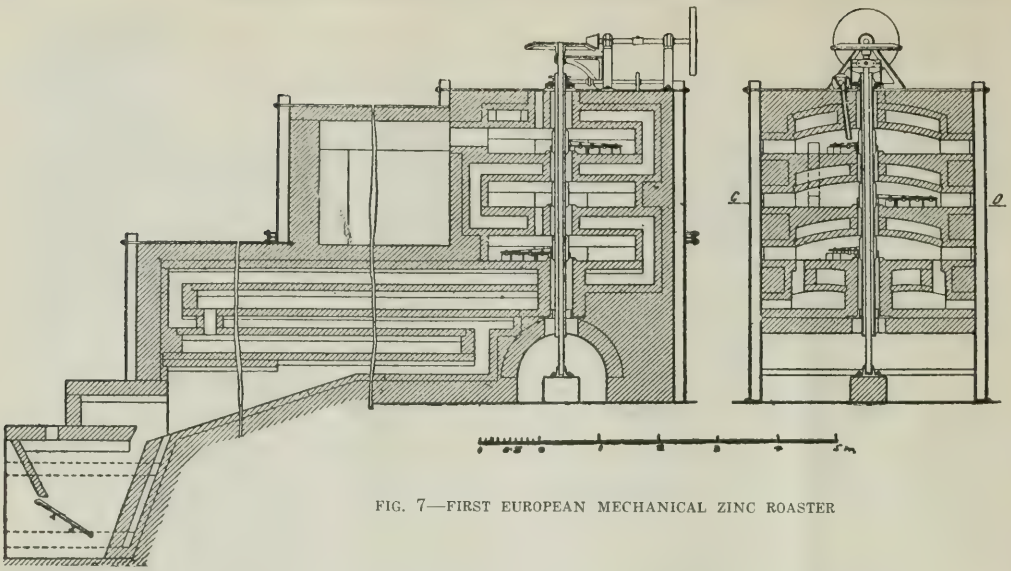


FIG. 7—FIRST EUROPEAN MECHANICAL ZINC ROASTER

found unsatisfactory and have been repeatedly rebuilt. They were not strong enough for the work and were redesigned before being built in Russia. No reports of the results of this installation have yet been published.

The Wedge furnace is now being tried on zinc ore in America.

Figures 10 and 11 show the Spirlet furnace, of which several were at work in Belgium and Germany at the outbreak of the war, and some have also been built in America. The capacity of the furnace is 3 to 3½ tons per 24 hours, and in consequence of there being no metal parts inside the furnace in contact with the ore the fuel consumption is low. The alternate hearths rotate and the ore is stirred by means of special bricks projecting downward from the hearth above. Good results have been obtained, but the campaign is short, and as soon as one or two of the projecting bricks, which stir the ore, wear or break off, the furnace chokes and has to be cooled down and put out of commission. I understand that on the Continent it has only been possible to work a furnace continuously for a maximum of three months before the arches have to be removed and overhauled, because no repairs can be carried out while the furnace is working.

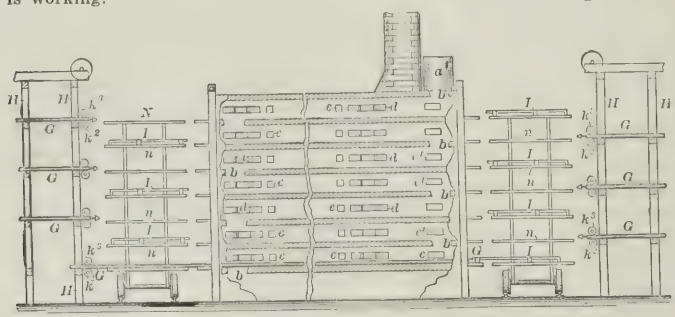

FIG. 8—HEGELER FURNACE
Longitudinal, vertical section

RIDGE MECHANICAL FURNACE

Figure 12 illustrates the general design of the Ridge mechanical zinc blende furnace, in which, after experiments extending over many years, the mechanical arrangements have been so far worked out that freedom from mechanical difficulties is assured, while the whole furnace is accessible. The shafts are each made in one piece and are water-cooled; about 15,000 gal. of cooling water is passed through the shafts in 24 hours to prevent overheating. The rabbles which stir the ore are easily and quickly renewed and the part to be replaced weighs only 5 lb. The ore is fed continuously to the drying hearth on top of the furnace and passes over three roasting hearths and finally to the cooling hearth, where it serves to preheat the air required for the oxidation. The mechanism of each furnace is driven by a separate electric motor which takes 8 to 10 hp. The motor and all the gearing are on a solid foundation beneath the furnace and fully accessible. The discharge opening is separated from the gearing by a brick wall to keep out all dust. The furnace runs noiselessly, the only sound being the hum of the motor. It is fired with producer gas which is burned only under the bottom roasting hearth. Broken Hill zinc concentrates are roasted down to 0.75 per cent total sulphur with a feed of 12 tons of ore per day of 24 hours and a coal consumption of 10 per cent. The sulphur fumes leave the furnace with 6½ to 8¼ per cent sulphur dioxide and at a temperature of 380 deg. C., so that they can be used satisfactorily in the lead chamber process. One man per shift can attend to the furnace and the producer.

Zinc concentrates with 14 per cent lead have been satisfactorily treated and also concentrates with 17 per cent iron. When roasting

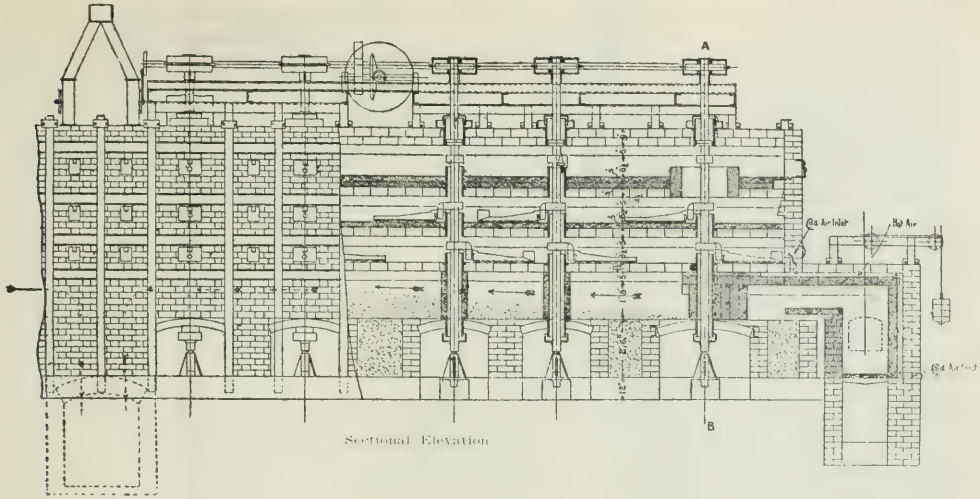

FIG. 9—MERTON FURNACE

an ore high in lead or iron, it is essential that a mechanical furnace be kept working continuously, because half an hour's stoppage means that the ore on the hearths sets hard and forms lumps which have to be broken up. It has been found possible in this furnace to use the rabbles for breaking up the lumps, and the gearing can, if necessary, be run alternately backward and forward till the hearths are free.

OPERATING DETAILS

I have dealt at length with the design of furnaces for roasting the ore, because this question has played such an important part in the past history of the art. The utilization of the sulphur contents of the ore, and, in fact, the treatment of zinc blende, has only become possible in consequence of the development of furnace design.

In some ores the presence of substances which interfere with the desulphurizing is important; lime, magnesium, strontium, and barium, if combined with sulphur, retain it in the roasting furnace; if combined with carbonic acid, this is driven off and in some cases the lime, etc., will take up sulphur from the ore. In considering the sulphur contents of roasted blende, allowance must be made for this combined sulphur. Lead becomes a nuisance in hand-rabbled furnaces, but in a properly designed mechanical furnace I have found no trouble; if ore high in lead is treated continually an accretion will form on the hearths, but the rabbles can be made to remove this. High iron content is found in some Spanish and German ores and makes complete roasting in hand furnaces almost impossible; in Germany, I was able, in a mechanical furnace, to reduce the sulphur left in the roasted ore to more than 1 per cent less than had been possible in hand furnaces.

USE OF SULPHUR DIOXIDE

The sulphur dioxide given off in roasting is utilized for making sulphites, liquid SO_2, or sulphuric acid.

Aluminium sulphate has been made at Flone in Belgium by passing the roaster gases into large chambers excavated in the hill side and filled with alum shale. At Ampsin this method was also used for making alum with gas from reverberatory furnaces; it seems that sulphite is formed and this readily oxidizes to sulphate.

The manufacture of liquid SO_2 was started by Grillo at Hamborn in Westphalia, because the fumes from the roasting furnaces were low in SO_2, and it was, at that time, considered impossible to utilize them for making sulphuric acid. The furnace gases pass to a scrubbing tower sprayed with water, which dissolves the sulphur dioxide, and the liquor gravitates to a series of pans, which are placed over the burners, the heat of which is sufficient to drive off the SO_2 gas. This, after being cooled, is compressed and liquefied at a pressure of 7 atmospheres. In Germany two plants are in operation, viz., one at Hamborn and another at Lipine in Silesia, but, in this country, the method has not been employed on the fumes from zinc ore. The demand for liquid SO_2 is limited.

The main commercial use for the sulphur fumes is the manufacture of sulphuric acid. This manufacture is well established at many smelters, and can be carried out in lead chambers, or by the contact process.

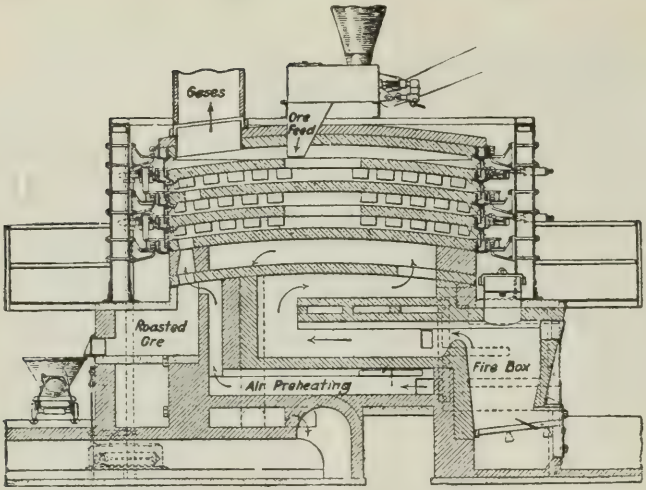

FIG. 10—VERTICAL SECTION THROUGH THE SPIRLET ROASTING FURNACE

EFFECT OF IMPURE GAS IN SULPHURIC ACID MANUFACTURE

Most zinc ores offer the advantage of being free from arsenic, but on the other hand they frequently contain fluorine of which even as little as 0.01 to 0.02 per cent becomes noticeable. Fluorine occurs with the ore as calcium fluoride, which is decomposed in the roasting furnace in the presence of silica and forms silicon fluoride. If this gas passes into the Glover tower it is decomposed and hydrofluosilic acid is formed; this, in turn, appears to split up. As it is usual, when treating zinc ores, to circulate the tower acids, the fluorine contents seem to remain in the circuit so that the attack on the packing of the towers gradually increases, but, contrary to expectation, I have not found increased corrosion of the lead work of the chambers by fluorine. Many efforts have been made to overcome the trouble with the packing. Glover towers have been built entirely of lead, and with lead sheets as a packing, so as to avoid the use of silicious material, but it is found necessary in this case to use two Glover towers in series, the first one being an empty tower followed by a tower filled with suspended lead sheets. I have found it preferable to overcome the trouble by passing the whole of the chamber acid through the towers instead of only circulating the tower acids, and by this means keeping down the fluorine contents of the acid, and at the same time to pack the towers with a well-burnt brick packing of a suitable composition which would offer the maximum possible resistance to the attack of hydrofluoric acid. Glover towers built in this way, and properly operated, have been worked continuously for 12 months and longer without trouble.

Other important impurities affecting sulphuric acid manufacture are antimony, mercury, and chlorine.

Some years ago I experienced trouble in consequence of the unexpected presence of chlorine, and on investigation I found that this was due to the ore having been left lying for several months on the Wharf at Port Pirie, and sprayed with sea-water in order to avoid loss by windage.

Mercury is found in some Spanish blendes. It collects at the outer parts of the dish of the lead chamber, where it is not protected by lead sulphate and causes rapid corrosion of the lead. This can be overcome by lining the sides of the dish with thin brickwork.

Antimony occurs frequently in small quantities with zinc blende, and at the high temperature of the roasting furnace some of this is volatilized and passes into the acid. On one occasion I received serious complaints about the presence of arsenic, but found, on examination, that antimony was the cause of the trouble. Antimony was found in the zinc concentrates from Broken Hill when treating ore from the upper levels in one of the mines, but the quantity present was less than 0.03 per cent.

Most zinc ores have lead associated with them, and some of this is generally driven off with the sulphur in the roasting furnace together with the silver which is combined with the lead, but both the lead and the silver are deposited in the chamber sludge.

SULPHURIC ACID PLANT OPERATION

The lead chamber process, when working with hand furnaces, has to be carefully watched because of the intermittent evolution of sulphur dioxide in consequence of intermittent rabbling of the ore. In Germany it has been usual to reduce this difficulty by arranging for the furnace hands, working on the different furnaces, to start their shifts at different times, but, in spite of this, it is not possible to obtain a continuous current of uniform gas throughout the 24 hours, and, unless the

FIG. 11—VIEW OF ONE OF THE HEARTHS OF THE SPIRLET FURNACE

process is watched carefully, loss of nitre is the result. With modern mechanical furnaces this trouble does not occur.

The design of the chamber plant does not call for special comment. It is in every way similar to that used when burning pyrites. The nitre consumption, and working cost of the plant, are not higher than with pyrites. In England and in Belgium lead chamber plants have been used exclusively for making acid, and in Germany this is also the rule, but there are several contact acid plants at work as well. In America 14 zinc smelters make sulphuric acid, but they mainly use the contact process.

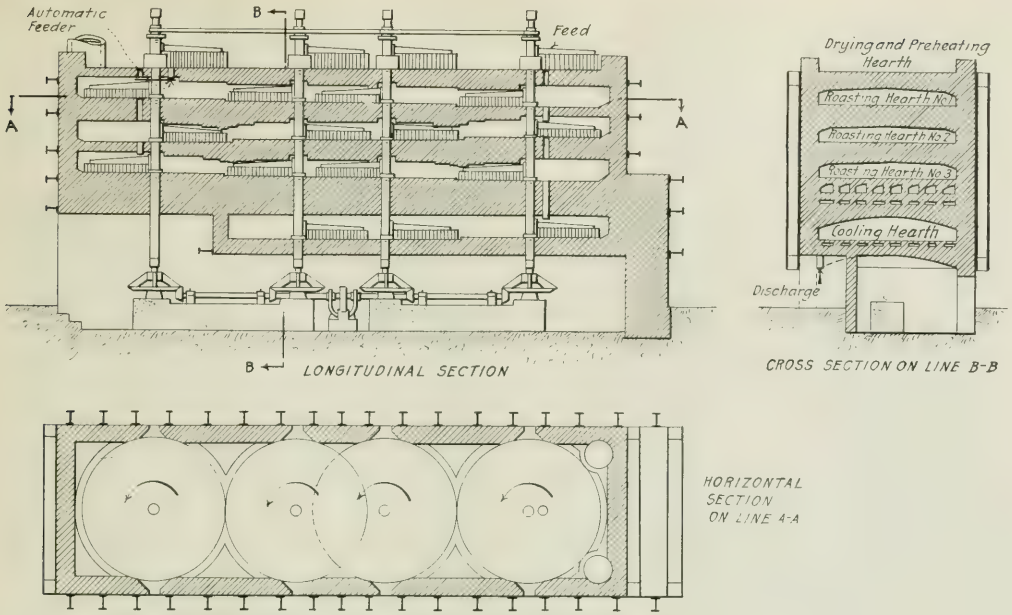

FIG. 12—RIDGE FURNACE

Calculated as 60 deg. B. acid, the American production from zinc blende was:

In the year 1911—230,643 short tons.
1912—292,917 short tons.
1913—296,218 short tons.
1914—411,911 short tons.
1915—484,942 short tons.

The average price realized in 1915 was $8.85 per short ton.

The use of the contact process for fumes from zinc ore made the biggest strides in the United States, because there the smelters are largely able to rely for their ore supplies upon the produce of one or more mines, and are not dependent upon small parcels of ore shipped from various parts of the world, as has been the case in England and on the Continent. They have consequently been able to make provision for eliminating any harmful ingredients which may be present in the raw material which they expected to be treating for a long period. The American smelters also have the advantage of having practically no hand-rabbled furnaces.

The various contact poisons can be eliminated if the tonnage to be treated warrants the initial expenditure on the plant. Fluorine, arsenic, antimony, and lead can be removed by first scrubbing the gas with a suitable liquid, and when this is done the conversion offers no greater difficulties than when brimstone or pyrites is burnt.

In England, acid has only been made from zinc ore in three plants, and I estimate that their output does not exceed 25,000 tons a year of 140 deg. Tw. acid. This tonnage corresponds to a production of about 10,000 tons of spelter. In 1913, 31,290 tons of virgin spelter was made in the country. Part of this was made from calamine, but the available supplies of this ore are steadily decreasing, and it is only a question of a short time, when the whole of the metal will have to be smelted from zinc blende. The position is really worse than is indicated by these figures, because it has been customary to roast the sulphide ore in reverberatory furnaces from which the fumes cannot be used, so that the sulphur is wasted and the atmosphere polluted.

PRE-WAR GERMAN PRACTICE

To illustrate the importance of the utilization of the sulphur of zinc ores I will refer to the figures for Upper Silesia. The district produces about 60 per cent of the spelter made in Germany, but a good deal of calamine is still available there, so that the maximum production of sulphuric acid from blende has not been reached; the tonnage of calamine treated steadily decreases, but the increased amount of blende compensates for this, and allows of an increasing spelter and acid production. The last figures available are for 1911, and the accompanying table shows the results for every fourth year since 1887.

STATISTICS FROM UPPER SILESIA

Year	Raw Blende Roasted. Metric Tons	Sulphuric Acid Reduced to 50° B. Metric Tons	Sale Value Total Marks	Sale Value Metric Ton of 50° B. Acid
1887	53,882	21,013	479,000	22.81 marks
1891	66,236	32,676	746,000	22.85 marks
1895	81,857	33,229	778,000	23.43 marks
1899	123,602	64,029	1,074,000	16.77 marks
1903	187,596	104,268	1,728,000	16.62 marks
1907	424,006	139,840	2,187,000	15.65 marks
1911	411,352	213,317	3,025,000	14.18 marks
1912	.....	254,008	.....	....

1 mark = 23.8 cents.

Six works still used their old reverberatory furnaces, so that not all the sulphur could be utilized, but for some years factory legislation has prohibited the emission of noxious fumes and as the plants become worn out they have to be replaced by modern installations.

The fumes from the reverberatory furnaces are scrubbed with milk of lime which is sent to waste. Five plants have lead chambers and make acid of 50-55 deg. B.; this is generally concentrated in cascades or Kessler apparatus and in recent years largely in Gaillard towers. Three works have contact plants as well as lead chambers. There was in 1912 a total of 48 lead chambers.

Of the total production of acid, 41,055 metric tons was sold as acid of 50 deg. B., 114,346 metric tons was sold as acid of 50-60 deg. B., 42,349 metric tons was sold as acid with 98-100 per cent H_2SO_4, 216 metric tons was sold as oleum with 20 per cent SO_3, 4774 metric tons was sold as SO_3, and in addition 2855 metric tons of liquid SO_2 was made.

The acid is used for making superphosphates, sulphate of ammonia, dynamite, and guncotton, and for refining mineral oil. It is distributed by rail over a wide area, some going into Russian Poland, Austria, Hungary, and even to Roumania.

The position in the zinc smelting districts in Western Germany is analogous, but there the make of acid is larger in proportion to the production of spelter, because there is no local supply of calamine. The newer smelting works have been placed on navigable waterways so that freights on raw materials and finished products are low. The chamber process is used in all the works except one which has a contact plant; there is also one installation making liquid SO_2.

In 1913 in Germany 554,760 metric tons of blende was roasted for making sulphuric acid; of this 87,439 tons was imported from Australia and 56,181 tons from other countries.

In Belgium blende is mainly roasted by the chemical manufacturers, who retain the sulphur and receive from the zinc smelter in addition a payment of $1.20 to $1.60 per metric ton, for roasting the ore. This was facilitated by the low freights on the canals, which reduced transit charges to a very low figure. In Belgium 65 per cent of the total production of sulphuric acid is made from blende; the amount of zinc acid is nearly 400,000 tons.

ENGLISH SITUATION

The most important and serious factor for consideration here in England is the shortage of zinc smelting capacity in the country. In 1913 our consumption of spelter amounted to no less than 224,000 tons of which 74 per cent was imported. After allowing for the metal made by the refiners, we imported about 166,000 tons of spelter and zinc in other forms. If this quantity were all made from blende, the roasting fumes could be used to produce annually 400,000 tons of 140 deg. Tw. acid. There is no reason why this should not be done and the corresponding quantity of brimstone and noncupreous pyrites displaced as well as a portion of the pyrites which is low in copper.

Before the war the cost of making 140 deg. Tw. acid from zinc ore fumes in this country was only between $1.95 and $2.20 per ton, so that the operation is remunerative and profitable.

Zinc ore must be treated because spelter is required, and if the work is not done here, it will be done elsewhere. Cheap sulphuric acid has always been an important factor in the chemical industries, and unless we use the resources of the Empire, others will do it for us and we shall be obliged to continue to look on while the foreign subsidiary industries using the acid abroad go ahead.

Several of the illustrations reproduced in this paper are taken from Liebig's "Zink und Cadmium," Ingall's "Metallurgy of Zinc and Cadmium," Prost's "Cours de Métallurgie de Métaux autres que le Fer," and "The Engineering and Mining Journal."

London, E.C.

Meter Accuracy on Arc Furnace Loads

In electric arc-furnaces used in making high-grade steel, the current wave shape is at times greatly distorted. A member of the Committee on Meters of the Technical and Hydro-Electric Section of the National Electric Light Association reports that the accuracy of an induction meter on this service was questioned because the magnetic and electrical characteristics of iron vary somewhat with the shape of the current wave. On account of the rapidly fluctuating load, indicating instruments could not be used, and dynamometer-type watt-hour meters without any iron in their magnetic circuits were specially compensated for inductive loads and used as standards, and the readings of the induction-type watt-hour meter compared therewith. The meters were installed on the secondaries of current and voltage transformers. A large number of tests were taken under various conditions of furnace operation, and the dynamometer and induction-type meters agreed to within 1 per cent. The instrument transformers were tested by the Electrical Testing Laboratories under artificially distorted wave forms, and were found to be accurate. The laboratory wave forms were not quite as irregular as the actual furnace current waves, but were severely distorted, and as they produced no appreciable effect on the transformer accuracy it was assumed that the effect of the slightly greater irregularity in the furnace wave would be negligible. It was concluded that under the conditions existing in this installation the accuracy of registration of the customer's meter was well within commercial limits, and was not seriously affected by the irregular wave form.

It is important to note that in the furnace electrode circuits considerable direct current was present, due probably to rectification in the arc, and consequently the current wave shape was unsymmetrical with respect to the zero line. The general shape of the wave was such as would be produced by superposing direct current on alternating current, and it was found that current transformers had large errors on this type of wave. If, therefore, the customer's meter had been placed in the secondary circuit of the supply transformers, instead of in the primary, serious errors in registration would probably have resulted. Pending further investigation, it is therefore recommended by this committee that if arc furnace loads are metered on the secondary side of the supply transformers, the accuracy of the metering should be investigated. If metered on the primary side of the supply transformers, errors will be avoided as the direct current in the electrode circuits cannot reappear on the primary side, hence the primary current wave is symmetrical with respect to the zero line. Summing up the results, it appears that no serious error is produced by an irregular current wave form, but if the wave is unsymmetrical with respect to the zero line considerable error may occur.

The Production of Salt in Szechuen Province, Western China—II

By H. K. Richardson

In a former article, in this journal, Jan. 1, 1917, p. 32, a description was given of the most famous salt wells of Szechuen province, China, those at Tzeliutsing. The present article will deal with the more numerous type of wells, those of moderate depth, about 1000 ft. This type of well can be found all over the salt well district (see map in former article), sometimes in groups and sometimes as isolated units. The largest collections are in order of their size found at Tai Ho Chen on the Chengtu-Wan Hsien post road, at Chein Wei Hsien near Kiating on the Min River and near Chien Chou on the Chengtu-Chungking Big road. The technique at the various places is very similar, the main difference being in the means employed to raise the brine. At Chien Chou the brine is raised by cows using a horizontal wheel on a smaller scale like that at Tzeliutsing, while at the other two places a vertical wheel operated by man power is in use. In all three places the supply of brine is limited, dependence on natural seepage of water to the salt deposit being universal, so that the raising process is intermittent.

A well visited in the Tai Ho Chen section is typical of this class of wells. The facts gained from the owners and operators will be given below.

The first operation is to locate the place to drill the well. For this purpose the owner calls in an expert called in Chinese, the "Salt Well Look Master." This man takes a stick and prods over the land until he is satisfied that a successful well can be driven. His word is taken and drilling commences at the spot he indicates. How often the look expert makes a mistake is not stated, but the number of unsuccessful wells in these territories is apparently small.

DRILLING

The spot settled upon the first operation is the construction of a winding drum, which will serve as the drilling drum and later for the winding drum of the finished well. Fig. 1 shows one of these drums set up by the side of the road. These drums have the following dimensions:

Diameter of the wheel	10 to 12 feet
Width of face of wheel	4 feet
Number of spokes in wheel	12
Material of wheel	Bamboo
Material of Hub	Pine Wood

The slats on the face of the wheel extend over the edges so as to give the men a footing when operating the wheel treadmill fashion. The rope which holds the drill or the bailer is wound over the periphery of the wheel between pegs. The winding drum finished, the top of the well shaft is sunk. A hole is dug about 40 ft. deep and lined with a wooden tube made by hollowing out a tree trunk. This serves as the drilling guide to insure vertical drilling and later as the top of the well. The construction of the top of the well is seen in Fig. 2. The drilling is done with a flat face spud drill (Fig. 3), 5 ft. long, above which in a bamboo case is a sinker bar about 15 ft. long. The whole outfit weighs about 150 lb. The actual drilling operation is simple, three men stand at the back of the drum and pull it back against a stop, then release the drum which flies back against another stop. During this operation the drill is raised 4 in. and suddenly dropped. This performance is kept up until the hole clogs with debris when a sand sucker or bamboo tube is lowered into the hole and the place cleaned out. In soft sand and hard clay progress at the rate of 8 ft. a day is the average. Tradition has it that 120 days is the average time to drill wells in this district. This would make the average well 1080 ft. deep. As an example of how trustworthy the average given by a Chinese is, the following figures are interesting: The rope strands on several wheels were counted: One wheel gave 27 layers on 12-ft. wheel or

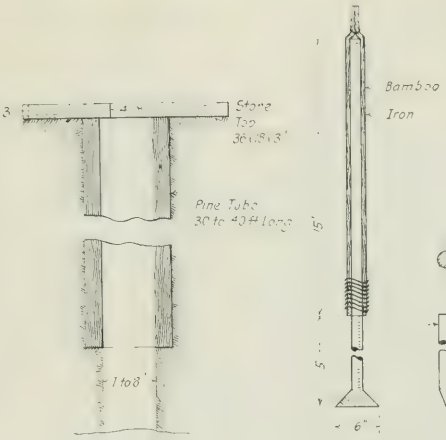

FIG. 2—WELL THROUGH CLAY AND SANDSTONE 1000 FT. DEEP

FIG. 3—FLAT FACE DRILL

FIG. 1—WINDING DRUM

FIG. 4—EVAPORATOR HOUSE, TAI HO CHEN

1020 ft. + 60 ft. (Bailer) = 1080 ft.; another wheel gave 33 layers on 10-ft. wheel or 1037 ft. + 60 ft. (Bailer) = 1097 ft.

RAISING THE BRINE

The brine is brought to the surface in a bamboo tube or bailer 60 ft. long, 1½ to 2 in. inside diameter holding about 83 lb. of brine. The bailer is supported by a bamboo rope made by splitting bamboo into strips 1 in. wide by 3/16-in. thick, and tying the needed number of sections together. Only two lifts are made a day, one in the early morning before the farmer starts his daily routine and one in the late afternoon as the sun is setting. It was an interesting experience to listen to the squeaking of the wheels as the farmers singly or by pairs laboriously, treadmill fashion, droned away the twenty or more minutes needed to bring the 80 odd pounds of precious salt brine to the surface. The salt is in about a 10 per cent solution. Nearly all the wells are operated by farmers as an adjunct to their regular work. The investment in one of these wells, not including the land, is small, about $36 on the average for the well, drilled and fully equipped. The brine is sold to the nearby evaporator on the basis of its salt content; the farmer makes about 5 cents a day or 40 per cent on his investment without considering his time.

These wells are very popular with the farmers in this district. In a journey of about 20 miles we counted from the road 475 wells, and 14 evaporator houses.

EVAPORATION OF BRINE

There is usually one evaporator situated about at the center of 30 wells. Fig. 4 is a photo of one of these houses. They are about 40 by 40 ft. and easily distinguished by their monitor roofs from which steam is always escaping. The arrangement of these plants follows one general plan such as given in Fig. 5. An interior photo is shown in Fig. 6. Probably since the first evaporator started they have followed the same scheme of operations as is given in the flow sheet which follows:

FIG. 6—INTERIOR OF EVAPORATOR HOUSE

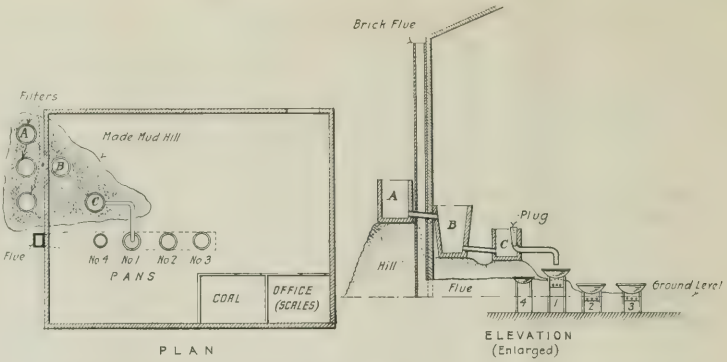

FIG. 5—ARRANGEMENT OF PLANT

FLOW SHEET OF EVAPORATOR

Letters refer to Fig. 5
Brine dumped on Filter A—5760 lb. per 24 hours
Filters to (B)
Filters to distributing tank (C)
To Pan No. 1
Drips slowly from Pan No. 1 into Pans Nos. 2 and 3

Scum	Brine
To pan No. 4 (waste heat)	Evaporated to dryness
Dried in pan	2" salt layer broken up for market
Sold for use in making bean curd	Yield per day about 165 gin per pan
This is $CaSO_4$	Total pans 2 and 3 . 440 lb. salt

Yield per day 7 lb. Value 1 cent Value—$5.94

The balance sheet of this evaporator as best we could get it from the man on duty is as follows:

Income for One Day

440 lbs. salt	$5.94
7 " $CaSO_4$	0.01
	$5.95

Outgo for One Day

800 lbs. coal	$2.35
36 loads brine	1.80
4 Workmen wages	0.27
Interest on investment and repairs to pans	0.40
	$4.82

The investment, as we were able to piece it together from the information given by the owner and our own experience, is as follows:

Building	$350.00
Pans	100.00
Tools, scales and misc.	50.00
Total	$500.00

The technical results obtained at this evaporator compared with those on the Chien Chow district are of interest.

	Chien Chow	*Tai Ho Chen*
Depth of well	500 ft.	1000-1100 ft.
Motive power	Cows	Human
Brine strength	12%	10%
Coal consumed per lb. of salt obtained	3.2	1.8
Pounds of water evaporated per lb. coal	2.8	6.7

The location of the wells in both districts, clustered around the bottom and partly up the sides of low hills, (60 wells were about a single small hill) suggests that the deposit from which they all were fed is a rock salt bed underlying the whole section. This deposit, if worked by a shaft and modern mining methods or by forcing down hot water as is done in some of the wells in the Middle West would yield its wealth with much less labor than is needed by the present methods.

A concluding article of this series will describe the well at Kwei Chow Fu, which has a technique all of its own and very interesting to the chemical engineers.

The Estimation of Petroleum Reserves*

By Robert W. Pack†

INTRODUCTION

Sooner or later in the development of any natural resource it becomes highly desirable to know the quantity of this resource in the country as a whole, as well as of the part that is being developed, for the general course and conduct of the development work must be governed to some extent by the total supply available. An accurate estimate of the quantity of any natural resource is difficult to make; yet if one is diligent enough one can obtain a pretty accurate idea of the quantity of marketable timber, the acreage of tillable land, or the horsepower that may be developed from the streams, for these are things that may be measured. But any attempt to estimate the quantity of some mineral in the ground appears to enter the realm of imagination and it seems that the estimate can be nothing more than a blind guess. It may appear to be especially futile to attempt to determine the quantity of oil and gas that is available in the ground, for these minerals are so vagrant that even if the quantity now available should be known quite exactly, the quantity that will eventually be obtained may be much less, for certain losses in the extraction of both oil and gas are unavoidable, and just what these losses will be cannot be predicted.

Though necessarily inaccurate, estimates of such mineral reserves are, however, of distinct value, for they summarize the existing knowledge of the deposits of the mineral and thus enable those who are interested in some industry that depends in one way or another on this mineral to formulate a rational commercial policy.

Some time ago, when the price of gasoline suddenly rose in a rather spectacular manner, the writer was one of the U. S. Geological Survey geologists called upon to help to estimate the quantity of oil that could be obtained in the United States, for the fear had become widespread that perhaps the rate of increase in the price of gasoline was a measure of the rate of depletion of the supply of petroleum. It thus became his official duty to make some sort of an estimate of the quantity of oil that still remained available in the ground in California. In making this estimate the writer attempted to predict the future output by a study of the past output of the productive fields, for such a mode of prediction is generally by far the most satisfactory one that can be used and has been employed in one form or another a great many times. There are, however, various ways in which historical and statistical data may be used, some being best suited for one set of conditions, some for another. The writer believes that the particular methods which he used in handling the data, and which are described below, are peculiarly adapted to the conditions in California, and that they are in considerable part new.

It is the purpose of this paper (1) to outline briefly one or two of the methods that have been used by others in estimating the available supply of oil, and (2) to describe somewhat more in detail the methods used by the writer, and to state why such methods were chosen and what degree of accuracy can be attained by using them. The general method followed might be applied to any oil field, provided the necessary data are available.

There are two general methods of estimating the quantity of oil and gas in the ground. The first of these to be described is what is commonly known as the saturation method; the second has been termed the production curve method. The two methods are not quite comparable, for the first is used to determine the quantity of oil in the ground, and the second the quantity of oil recoverable, assuming that the conditions governing production will continue to be about the same as they have been in the past. The two methods likewise have separate applications, for the saturation method may be used to determine roughly the quantity of oil or gas in an area that has not been tested, whereas the production curve method is applicable to a partly developed field but only indirectly to an undrilled area.

SATURATION METHOD

The saturation method consists essentially of a determination: (1) of the volume of the strata that serve as reservoirs for the oil; (2) of the porosity of these strata—that is, of the "voids" in them—and thus of the maximum volume of the space that may be occupied by the various fluids; and (3) of the percentage of the "voids" that is occupied by oil. This method is the one that has commonly been used ever since estimates of the oil reserves of the country were first attempted. The method has recently been described in some detail by Washburne.[1]

The saturation method obviously involves the consideration of several factors that cannot be measured directly. The first factor to be considered—the volume of the sand that serves as a reservoir—is the factor that may be determined most accurately, and in fields where the strata show relatively little variation in lithology and thickness over large areas, such as the Appalachian fields, it may be possible to calculate the volume with considerable accuracy from measurements made on the outcrops of the oil- or gas-bearing sand, or from those given by a few scattered wells. In a very great many areas, however, and of these the California fields are fairly typical, the formations are so lenticular and the reservoir sands so inconstant both in thickness and in lithology that no reliance can be placed on the calculations of the volume of the reservoir made in this manner, even if the points at which the measurements were made lie fairly close together.

The second factor, the porosity of the reservoir sand, is even more difficult to estimate. In making an estimate of the oil, it is clearly useless to determine the porosity of the oil-bearing sands in areas where the total volume of the strata cannot be determined with some degree of precision; but even in areas in which the thickness of the formations is fairly constant, and in which the volume of the beds acting as reservoirs may be calculated with fair precision, the porosity may vary greatly, either because of variation from place to place in the grain of the rock or because of the local introduction of a secondary cement that occupies a considerable part of the original void space of the rock; and the variation may be so great that the space which may be occupied by fluids cannot be calculated. In these areas the porosity of the oil-bearing bed as determined from samples of rock taken on the outcrop or from a few samples obtained in drill holes is apt to be very differ-

†Geologist, United States Geological Survey.

[1] C. W. Washburne: (1915) 51 Trans. A. I. M. E. 645.

ent from the average porosity of the stratum over a large area.

The third factor, the percentage of the void space that is occupied by oil, is, of course, not directly measurable, so that it is necessary to assume either that the voids are all so occupied or that some arbitrarily chosen proportion of them are.

Should all these different factors be correctly determined, the resulting figures will record the total quantity of oil in the field. Not all this oil is recoverable, however, and the figures so obtained must be mutiplied by an "extraction factor" in order to obtain figures that will represent the available oil.

Even under the most favorable conditions, then, the saturation method is capable of giving only a rough approximation of the recoverable oil in any area; but rough as it is, this method has a distinct value, for it will give directly a first approximation of the maximum amount of oil to be expected from an untested or very sparsely drilled area in which the formations are fairly constant in thickness and lithology. This method is not, however, applicable to areas where oil is held in solution cavities or in fracture zones, nor is it of any very great value in the consideration of pools that occur in the variable Tertiary strata of California.

PRODUCTION CURVE METHODS

The production curve method is a mode of predicting the future production of an area and is based on a study of the past production of that area. The method is largely graphic, and although various modifications of it have been used, all are essentially extrapolations of one or more curves that show the production or development of the field. The advantages of this method over the saturation method are: (1) it is concerned with actual production, so that the assumption of any "production factor" is unnecessary; (2) the factors that must be estimated or assumed are fewer and on the whole less liable to great variation than those that must be estimated or assumed for the saturation method.

Two general methods of using production figures are employed in estimating the reserves of oil in a given area. One uses figures showing the production per unit of time of the whole field or of a group of fields within a given area; the other concerns itself only with the production of certain small areas, which are considered as types, the results obtained in their study being applied to the field as a whole.

In support of the first method, it has been urged that a consideration of the combined production of a large number of wells and of wells distributed over a large area automatically takes account of various irregularities in the production of individual wells—of irregularities due to variation in demand, to increased drilling, and to the discovery of new pools—it being always assumed, of course, that the conditions in the future will vary about as they have varied in the past. But in the very fact that the curve incorporates these factors lies its weakness, for in the nature of things drilling cannot continue indefinitely into the future, nor is it reasonable to expect the continuous discovery of new pools. These two factors should therefore be taken into account separately, and their effect should be eliminated from the curve showing total production.

The second method—that of studying the history of a small group of wells—has an advantage in that it permits a more intensive study, but it has a disadvantage in that the data necessary for this study are much more numerous and are seldom available. Moreover, in applying to the whole field the results obtained in the study of a small part of it, it is necessary to estimate the degree in which this area represents the conditions that exist throughout the field.

METHOD USING THE RECORD OF THE PRODUCTION OF THE ENTIRE FIELD

Probably the simplest method of predicting the future of a field is to project the curve that represents the field production per unit of time. Such a method will give reasonably correct results only for an old field in which the production of oil per unit of time has been constantly decreasing. When applied to the Appalachian fields it gives fairly satisfactory results. The method of representation shown in Fig. 1, in which the shaded area below the line *ABC* represents the volume of oil that has been produced to date from an old field, that has long been producing a constantly decreasing quan-

FIG. 1—ESTIMATION OF RESERVE OF PETROLEUM BY EXTRAPOLATION OF CURVE SHOWING FIELD PRODUCTION IN UNIT TIME

tity of oil in a given length of time. Assuming that this rate of decrease will continue until the field is completely drained, the amount of oil now remaining in the field is represented by the unshaded area below the line *CD*.

This method of prediction is open to the criticism that it does not discount the effect of new wells but that it tacitly assumes that new wells will continue to be drilled up to the very moment that the pool is drained, or, if the curve represents the production of a large area rather than of a single pool, that new pools will continue to be discovered up to the moment when the oil in the region is exhausted.

CURVE SHOWING PERCENTAGE OF DECREASE IN PRODUCTION

A variation of the graphic method of estimating reserves just described is to plot, not the figure showing the actual quantity of oil produced, but a figure showing the relation between this quantity and the maximum quantity of oil that the field has produced during some unit of time. The curve so obtained—the so-called percentage curve—was used by Arnold, and Fig. 2 is adapted from his plate.[2]

This mode of estimating oil reserves, like that just described, is applicable only to those fields that have passed the zenith of their productivity and are producing in any unit of time a constantly decreasing quantity of oil. The curve in Fig. 2 represents the life of the field after the time when the maximum yield per unit of time was obtained. It is so constructed as to show the quantity of oil obtained during each unit of time that followed the period of maximum yield, the quantities being expressed in percentages of that maximum. This method is also open to the objections that have just been raised against the method of projecting

[2]Ralph Arnold: The Petroleum Resources of the United States. (December, 1915), 10, *Economic Geology*, 695-712.

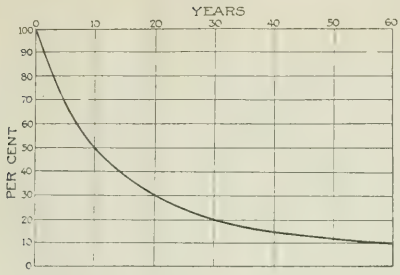

FIG. 2—ESTIMATION OF RESERVE OF PETROLEUM BY USE OF "THEORETICAL CURVE OF FINAL DECREASE"

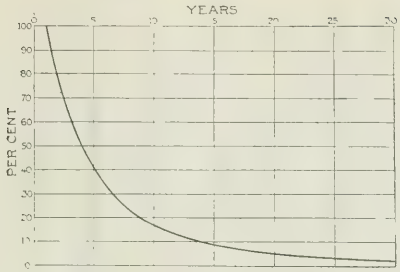

FIG. 3—ESTIMATION OF RESERVE OF PETROLEUM BY USE OF CURVE SHOWING PRODUCTION OF AVERAGE WELL EXPRESSED IN PERCENTAGES OF PRODUCTION OF WELL DURING FIRST YEAR OF ITS LIFE

the curve that shows the total production directly, particularly to the objection that it in no way takes account of the effect of new wells. The sole object of plotting the statistics of production in this form was to obtain a curve that would serve as a type to show decline in production for any and all fields. The rate of decrease in production, however, is so different for different fields that it seems very doubtful whether a single curve can express the decline for more than a single field, or perhaps for a group of fields in rock of the same general type or of the same general geologic structure.

This method of plotting production in terms of percentages of total production is essentially an attempt to apply to the country as a whole the methods employed by the California evaluation committee, whose work is explained below. That committee, however, concerned itself with small areas for which a mass of detailed information was available and constructed a number of curves, each showing the rate of decline for a certain particular field. An inspection of these curves, all of which were prepared for fields in California, shows that even within that State the decline is different for different fields. It is evident that similar curves constructed for fields in Oklahoma and Pennsylvania would show still greater differences. Moreover, the production curves of the evaluating committee were so constructed that the effect of continued drilling is to a measure discounted. The "theoretical curve of final decrease" used by Arnold does not in any way consider the effect of drilling new wells, but, like the method shown in Fig. 1, assumes that drilling will continue up to the very moment that the field is totally drained. This method, therefore, has less to recommend it than the method of projecting the curve showing the exact quantity of oil produced in some unit of time.

METHOD USING RECORD OF THE PRODUCTION OF SMALL AREAS

Some time ago, when a plan was on foot to combine certain producing properties in California, it became necessary to determine the relative value of the different properties, and especially the reserves of oil contained in each. A committee, of which M. L. Requa was the moving spirit, attempted to determine the reserves by making a detailed study of the history of the wells. The method that they followed was essentially the study of a small area in great detail, and the application of the results of this study to the field as a whole. The immediate problem was not to determine the reserve of oil in the whole field, for that was of only incidental interest, but the amount remaining in certain parts of the field. The areas studied, however, were regarded as types of the fields or of the parts of the fields in which they lay, and the curves showing the predicted production for the small parts were applied to the whole field.

Then, too, the manner in which they used the record of the production of the wells was unique. Instead of plotting a curve that showed the rate at which oil had actually been taken from the area—that is, instead of constructing what might be termed a chronologic curve—the figures showing the production of the wells were so grouped that the quantity of oil obtained from a well during each year of its life was grouped with the quantity of oil obtained from all the other wells during the corresponding years of their lives, irrespective of the actual time at which the wells were drilled. Thus, although well *B* may have been drilled 10 years later than well *A*, the oil that well *B* produced during each year of its life was grouped with the oil that well *A* produced 10 years before. The figures showing the production of the wells as thus grouped were then expressed in percentages of the production of the first year, and this curve was taken to represent the production of the average well in the area. To get a figure representing the quantity of oil that the average well will produce, it is necessary only to determine what the average production during the first year of their lives has been for the wells that have been drilled, and to substitute this number in the curve. The oil produced during the following years is then expressed in percentages of this number.

In order to obtain a figure representing the total production of an area, it is necessary to determine the number of wells that would be necessary to drill the area completely, and to multiply this number of wells by the figure showing the total quantity of oil obtainable from the average well, as shown by the curve. A curve constructed for one of the California fields is shown in Fig. 3.

This method has the distinct advantage over the methods hitherto described in that it attempts to determine the effect upon production of the rate at which new wells are drilled. The degree to which this discounting is really effected is, of course, dependent in large part upon the degree to which the property is drilled, for the mutual interference of wells increases as wells are multiplied.

METHODS USED BY THE WRITER

In casting about for some way in which to estimate the oil reserves in California, the writer, after consid-

ering the methods just described, concluded (1) that the production curve rather than the saturation method should be used in estimating the reserves in the producing fields, and (2) that the untested areas should be estimated by comparing them with the producing areas that they most closely resembled geologically, after the reserves in these areas had been estimated by the production curve method. The best way of handling the production record did not seem to be quite so clear, for none of the methods appeared quite to fit the requirements. It seemed better to use a method that considers the production of the whole field rather than with one that considers only a small part of it, both because the data necessary for the detailed study of a small area are seldom available and because of the difficulty in choosing areas that might fairly represent the whole field. It appeared, however, that in dealing with the record of the total production some way should be found to discount the effect of the new wells.

METHODS USING FIGURES SHOWING FIELD PRODUCTION

In order to fulfil approximately these requirements, the method described below was devised. Fig. 4 shows the application of the method to a California field:

1. The field production per unit of time was plotted and a curve, *ABCF*, similar to that in Fig. 1 was obtained.

2. Two points, *B* and *C*, which represented dates when the field production was the same, were selected. These points were as far apart as possible and corresponded to the general level of the curve about them—that is, they represented dates when the field production was fairly constant.

3. The number of the new wells drilled between the two dates represented by points *B* and *C* was then determined, this, of course, being a matter of record, and,

4. The number of new wells required to drill the field completely was then estimated from a knowledge of the geology of the field, it being assumed that the manner of locating wells would in the future be about the same as it had been in the past.

These factors having been determined, the supposition was made that, if new wells were drilled after the time represented by the point *C* at the same rate as they had been drilled during the period represented by the line *BC*, the production of the field would be maintained at a constant figure. This is not precisely correct, for the initial production of the wells that are drilled late in the life of the field is not nearly so great as that of the wells drilled while the field is new. The number of new wells necessary to maintain production will therefore increase as the field grows older. An idea as to this rate of increase in the number of wells necessary, may be obtained from a study of a cumulative curve showing the time at which new wells have been drilled and a curve showing the production of the field. The correction may be neglected in making the first approximation of the reserve of petroleum in a field, for other factors which enter into the calculation are liable to so great error that such a refinement seems insignificant, but in making a detailed study of a small area where a considerable number of reliable data are available, such a correction should be made. When the rate has been determined at which the drilling of new wells must progress in order to keep the output of the field constant, the time at which the field would under these conditions be completely drilled is calculated. This time is represented on the diagram by the point *D*. The quantity of oil which under these conditions would be produced between the time represented by point *C* and the time represented by point *D*—the time at which the field would be completely drilled—may be calculated or may be measured directly from the diagram. After the field is completely drilled a considerable quantity of oil will still remain in the ground and the field will continue to produce at a constantly decreasing rate. The rate of decrease may, however, be estimated fairly well, for it is unaffected by the flush production of new wells.

The most satisfactory method of making this estimate is to choose some small area containing a number of fairly old wells, preferably one in which all the wells were drilled at about the same time, and to plot the production per unit of time of this group of wells after the date at which the last well was completed. The resulting curve may be taken as typical of the last period of the life of the average well in the field and it may be applied directly to the curve *ABCD* at the point *D*, which represents the time at which the field is completely drilled.

It may so happen that the field has produced a constantly decreasing quantity of oil since almost the first year of its life and that it is not possible to find two dates far enough apart at which the total production was the same. It may be possible, however, that for a considerable time the decrease in production was fairly constant. If so, a calculation similar to that required in the preceding method may be made, with the difference that drilling is theoretically continued at a rate sufficient to maintain not a constant production but a regular decrease similar to that which takes place during the period chosen. Then, in a manner like that just described, the date at which the field would theoretically be completely drilled may be calculated and the production up to this time estimated. The oil remaining in the field after the completion of drilling could then, as before, be estimated by assuming that the rate of decrease of production would be like that shown by a typical group of old wells.

An application of this method is shown in Fig. 5. Here the shaded area below the line *ABCF* represents

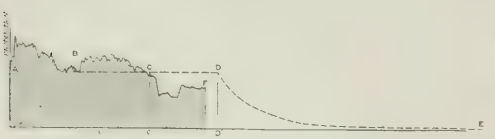

FIG. 4—ESTIMATION OF RESERVE OF PETROLEUM BY USE OF CURVE SHOWING FIELD PRODUCTION IN UNIT TIME ASSUMING THAT DRILLING MAINTAINS PRODUCTION OF CONSTANT FIGURE

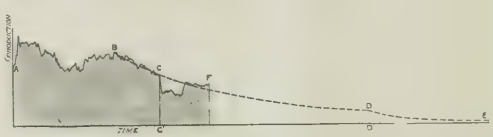

FIG. 5—ESTIMATION OF RESERVE OF PETROLEUM BY USE OF CURVE SHOWING FIELD PRODUCTION IN UNIT TIME, ASSUMING THAT DRILLING MAINTAINS PRODUCTION AT A UNIFORMLY DECREASING RATE

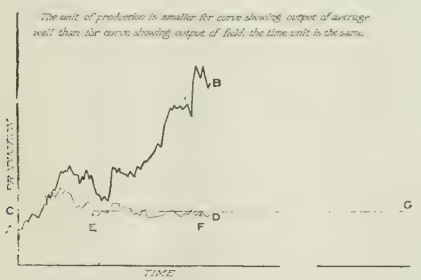
the volume of oil produced to date from the field. On the curve *ABCF* a section *BC* is chosen during which the decrease in production is fairly constant; the number of new wells drilled during this time is ascertained and, on the assumption that this rate of drilling will be continued from the time represented by point *C* until the field is completely drilled, the time at which the field will be completely drilled is calculated. This time is represented on the diagram by point *D*. The quantity of oil that will be produced between the time represented by point *C* and the time at which the field is completely drilled is represented by the area inclosed by the lines *CD*, *DD'*, *D'C'*, *C'C*. The oil that is contained in the field after drilling has been completed is represented by the area lying below the line *DE*.

In this method, as in the preceding one, the assumption that if new wells are drilled after the time represented by the point *C* at the same rate as they had been drilled during the period represented by the line *BC*, production would decrease at the rate at which it decreased during the line *BC*, is not quite correct. Because of the smaller initial production of wells drilled late in the life of the field, the number of wells necessary to maintain this rate of decrease in production of the field will gradually increase as the field is drilled up. A correction similar to that suggested in the method just described may be made here.

METHOD USING FIGURES SHOWING FIELD PRODUCTION EXPRESSED IN TERMS OF PRODUCTION PER WELL PER UNIT OF TIME

During the first few years of the life of a field, drilling is usually so actively carried on that the quantity of oil produced in the field as a whole during a given unit of time is constantly increasing. It is obviously impossible to apply either of the methods just described to this early period in the life of a field, for they are applicable only to a period when the field production per unit of time is decreasing. For many fields, however, a fairly satisfactory estimate may be made by expressing the production of the field per unit of time in terms of the production per well per unit of time, for although the production of oil obtained during a given length of time from the field as a whole is increasing, the production of the average well during equal intervals of time is the same or is decreasing. This method of estimating the petroleum reserves is not so accurate as either



The unit of production is smaller for curve showing output of average well than for curve showing output of field, the time unit is the same.
B

E
F
D
G
TIME

FIG. 6—ESTIMATION OF RESERVE OF PETROLEUM BY USE OF CURVE SHOWING PRODUCTION PER WELL PER UNIT TIME, ASSUMING THAT DRILLING MAINTAINS PRODUCTION OF AVERAGE WELL AT CONSTANT FIGURE

of the preceding methods, because it is based upon fewer data. It should not be used, therefore, if either of the other methods is applicable.

Fig. 6 shows the application of this method. The production of the field is represented by the line *AB*. This curve shows a constantly increasing value for the production of the field during a unit of time, so that the methods represented by Figs. 4 and 5 are not applicable. The production per well per unit of time is therefore determined, and the curve *CD*, showing these values, is plotted. On the curve *CD* the points *E* and *F* are chosen as representing dates at which the production of the average well—the production per well per unit of time—is the same. The rate at which new wells were drilled during the time *EF* is ascertained and, as before, the length of time necessary to drill the field completely is determined, it being assumed that drilling will be continued at a rate that will maintain the production of the average well at a constant figure—a figure equal to that of the average well at the dates represented by points *E* and *F*. A first approximation of this date at which the field would be completely drilled may be obtained by assuming that production would be maintained at a constant figure if drilling be carried on after the date represented by point *F* at the same rate as it had been carried on during the period represented by the line *EF*. To be accurate, this assumption as to the rate of drilling after the time represented by point *F* should be corrected to take into account the smaller initial output of the wells that are drilled late in the life of the field. The time at which the field would be completely drilled is represented on the diagram (Fig. 6) by the point *G*. Then if

a = the number of wells producing at *E*—the first date.

b = the number of new wells drilled during a unit of time in the period between *E* and *F*—the two dates chosen.

c = production of the average well in a unit of time during the period *EF*.

d = the number of wells necessary to drill the field completely. (This number may be estimated from a knowledge of the geology of the field and of the field practice in spacing wells.)

S = the total amount of oil that would be produced between dates *E* and *G*.

And assuming that new wells are drilled after the time represented by the point *F* at the same rate as they had been drilled during the period represented by the line *EF*, the total quantity of oil produced by the field from the date *E* until the field has been completely drilled would be given by the formula:

$$S = ac + (a + b)c + (a + 2b)c + (a + 3b)c + \ldots + dc = \tfrac{1}{2}n\,(ac + dc),$$

where n = the number of terms in the series.

But:

$$n = \frac{d - a}{b} + 1$$

therefore:

$$S = \frac{d - a}{2b}\,(a + d)c.$$

The total quantity of oil produced before the time represented by *E* should be a matter of record. The oil remaining in the field after it had been completely drilled under the conditions stated may be estimated as in the two methods just described by assuming that the

rate of decrease in production will be the same for the field as it is for a small group of old wells.

If the smaller initial production of the wells drilled late in the life of the field is considered and the rate of drilling of new wells corrected to show this factor, the formula given above will not apply. The curve shown in Fig. 6 may, however, be projected in a manner similar to that in which the curve in Fig. 4 was projected. This curve will show the total amount of oil that the average well will produce, from which the total reserve in the field may be calculated.

Should the field production be increasing, but the production of the average well decreasing, the size of the available reserve may be estimated by a method similar to that shown in Fig. 5, but with the difference that the production figures plotted express the production of the average well, and not of the field as a whole.

PROBABLE DEGREE OF ACCURACY OF ESTIMATES

All the methods of estimating petroleum reserves described above involve the consideration of facts that, in the very nature of things, cannot be determined precisely, and the results obtained, therefore, cannot be precisely accurate. The results obtained by the methods that take into account the greater number of the variable factors are probably the more accurate. The writer believes that the methods he used in estimating the reserves in California express correctly the order of magnitude of the reserve, but he would not claim for them greater accuracy than that.

The Design of Modern Coking Plants*

By E. M. Myers

It is highly important that the site chosen should be such that efficient drainage can be installed with comparative ease. For these reasons slightly sloping ground should be chosen, and the sewers and drains constructed to pass a quantity of water at least 50 per cent greater than the maximum amount estimated.

If a coal washery is necessary it should be placed as close to the mine openings as economically possible, and certainly separate from the coking plant.

Effective provision should be made for dealing with the large volume of dust produced at the surface plants, not only because such practice would save thousands of tons of valuable fuel, in the aggregate, but at the same time this would obviate a great nuisance.

Designers of elevators nearly always lose sight of the fact that some day it would be necessary to repair them, apart from the fact that it is always necessary to inspect them. If an elevator was so constructed that it is impossible for a man to conveniently climb up and down the buckets there will always be trouble. It is important that the washery should have a capacity well in advance of the demands of the coke ovens, so that it would not be necessary to work continuously, thus giving ample time each day for repairs and overhauling. The bunkers must be large enough to hold sufficient supply to enable the ovens to be worked for at least thirty-six hours after the supply to the bins had been cut off.

The coal washer should be under the direct supervision of the coke-oven manager. The quality of the washed slack is so important, both from the point of view of the resulting coke and the yield of by-products, that it is imperative the coke-oven manager should be able to control that quality.

Apart from the peculiarities of the coal to be used, the important features that ought to govern the selection of the type of oven are (1) simple and complete control of the heating of the walls, so that the temperature remains constant throughout as nearly as possible; (2) all those parts of the ovens connected with the working of the gas and air control must be easily accessible, with a minimum of discomfort; and (3) the oven is to be so designed that the heating arrangements and the flues can be easily inspected. If the regenerative type is chosen, then the regenerators should be so efficient that the amount of gas required for the heating of the ovens is reduced to the lowest possible minimum, so as to insure the greatest possible quantity of surplus gas. The air supply must be capable of simple adjustment, so that complete combustion can be easily obtained and a minimum of time required for carbonization. Finally, the construction of the ovens must be sound—a substantial foundation must be provided—and the ovens should be built in small units. Batteries of thirty are certainly easier to control, and in a large plant, could be more easily laid off for extensive repairs than could big batteries. The flues should be so arranged that the crown of the oven remains comparatively cold, to avoid destruction of valuable by-products; and the bricks used for building the oven chamber and flues should be of high-class material, capable of withstanding, not only the high temperature, but the stresses and pressures to which they are subjected. The actual building of the oven walls must be done in such a manner that all possibility of leakage from flue to oven is reduced to the lowest possible minimum, and the discharging end must be at least 2 in. wider than the charging end.

The question as to whether regenerative or waste-heat ovens are to be erected must be decided by local circumstances, which determine the most economical disposal of the surplus gas or waste heat. Since coke oven gas is coming more and more in domestic demand, the greater first cost of the regenerative type of oven should be carefully discounted.

Three systems of by-product recovery—direct, semi-direct and indirect—can be made to yield excellent results with care, but if the characteristics of the coal were carefully considered before the type of recovery process was decided, a great deal of needless worry could be avoided. Salty coals should not be dealt with by the direct method, and where coals of this kind had to be used the semi-direct system should be adopted. In fact, future plants should be constructed on either the semi-direct or direct systems, as it certainly could not be held that the indirect method was conducive to small ammonia losses.

It has always been held by blast-furnace men that a dense hard coke capable of withstanding a great burden is best for blast-furnace coke, and it has also been held that coke produced from compressed coal is capable of satisfying this crushing effect in the furnace much better than that produced from uncompressed coal. Although it can be admitted that compressed charges yield denser coke than uncompressed, it cannot be conceded that better results are obtained in the blast-furnace by its use. Compressed charges are always liable to break before getting them into the retort, and their successful

*An abstract of a paper read before the Coke Oven Managers' Association (British) on June 30, 1917.

use depends on (1) the moisture in the slack, (2) the fineness of the slack, (3) the ability of the man in charge of the machine, and (4) the condition of the oven walls. On the other hand, these points do not affect the success of the top-charging method coupled with some mechanical leveling apparatus. Then, again, any system of mechanical charging with compressed charges leaves a greater space between the top of the charge and the crown of the oven than does the mechanical leveler, and although the amount of coal charged per oven must be less in the case of top charges, the carbonizing period is likewise shorter.

If more attention was paid to the type of door used a great deal of time and worry would be saved. What is required is some provision to enable the door to be fastened in its place without resorting to the use of daub or luting to insure its being gas-tight. Mechanical handling of the oven doors should be provided wherever possible.

In regard to water, it might be accepted that 1¼ tons of water per ton of coke produced per day is sufficient for all purposes—condensing, coke quenching, scrubbing, boilers, etc. On large plants it would be found economical to erect a water-cooling tower of sufficient capacity for condensing purposes, provided the works are not situated close to unlimited supplies of good cold water.

Where it was decided to include a tar plant the question of pitch bays is important. These should be large enough to allow a quick and efficient cooling of the pitch, and so placed that the pitch could easily be loaded. The continuous tar distillation system is the best one to adopt, as repairs and renewals are much more easily carried out than in large intermittent plants.

The building for the exhausting and pumping plant should be provided with an overhead traveling crane, which will pay for itself many times over when the question of repairs and renewals comes to be faced. In fact, all the buildings containing plant that has to be cleaned or repaired should be designed in such a way that overhead lifting arrangements are permanently installed. The construction of adequate and sanitary change houses is very much to be recommended.

Shelton, England

Electrode Cooling

By Haakon Styri,
Metallurgist, Hussey-Binns Steel Co.

A simple arrangement of the water cooling on electrodes introduced by the writer, some time ago, on the Heroult furnace at the Hussey-Binns Steel Co. plant, has worked very satisfactorily. The accompanying sketch, showing the arrangement as applied to the middle electrode, gives the principle.

The cooling water comes through the armored hose (1) to distributing box (2), fastened on the outside of the columns for the electrode holders. Only three pipes go out from the distributing box—one to each electrode, and each of which is furnished with a regulating valve. Where the pipe passes the roof ring a piece of rubber hose (3) is inserted for insulation and connected with a union (4) to the pipe which goes to the cooling ring. The return pipe from the cooling ring is connected with a union (5) to the rubber hose (6), which is sufficiently long to allow for total electrode movement and some surplus to prevent kink. This rubber hose is again, by means of union (7), fastened to the pipe leading to the electrode holder, and the return pipe from this is, by means of union (8) and rubber hose (9), connected to the downfall pipe (10), which is fastened to the electrode carriage. From the pipe (10) the armored rubber hose (11) leads to the common waste-water box.

The advantage of the arrangement is that all pipes on the furnace can be very easily drained in case of cold weather, when the furnace is out of operation,

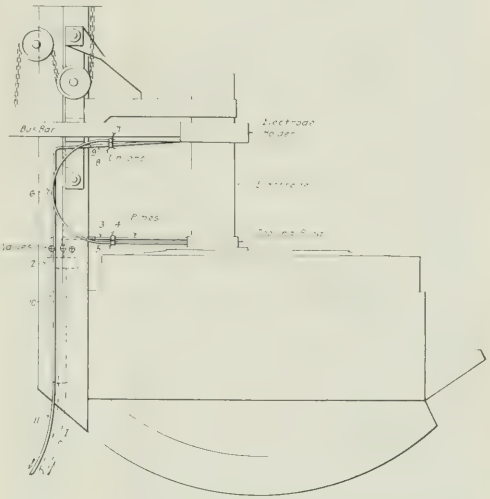

FIG. 1—ARRANGEMENT FOR WATER COOLING

and freezing of the water is to be feared. Disconnection of the unions of the armored feed hose (1) and waste hose (11) will give complete drainage.

In case muddy river water is used for cooling it is advisable not to thread the ends of the pipes on which the hose from the cooling rings are fastened. This avoids danger when, after a clogging up, steam will be suddenly developed in the cooling ring, causing the hose to blow off.

The further advantage is that very little rubber hose is used, and only three valves are to be operated by the furnaceman.

Pittsburgh, Pa

New Dyestuff Journal.—The *Color Trade Journal* is the title of a new monthly journal, the first number of which appeared in August. The Journal will be devoted to the interests of the manufacturer and user of dyestuffs, and is published by the Color Trade Journal, Inc., 200 Fifth Avenue, New York. The editor, Dr. J. Merritt Matthews, needs no introduction to chemists in this section, as he is a well-known expert on dyestuffs and the author of several books and many technical articles on their application. C. W. Butterworth is managing editor and Eugene C. Mayer business manager. The publishers are to be congratulated on the appearance and material of the first issue. The Journal should be of great assistance in bringing the needs of the users of dyestuffs before the manufacturers and in bringing about cordial relations between them, which is the best safeguard for our new American dyestuff industry.

The Utilization of Waste-Products and of Low Grade Fuels for Power Generation—II*

By John B. C. Kershaw, F.I.C.

THE USE OF COKE AND COKE-BREEZE.

The war has altered many old-established maxims in our industrial and economic life, and amongst the time-honored beliefs that have been thrown overboard is the idea that coke and coke-breeze are unsuitable fuels for steam generation.

The difficulties of burning coke or coke-breeze in the ordinary type of boiler furnace, provided only with natural chimney draft, had of course something to do with the existence of this idea. Every different type of fuel, however, requires special conditions for its complete combustion under steam-boilers. The fact that coke and coke-breeze could not be burned satisfactorily in furnaces designed and primarily intended for the combustion of bituminous coal was no proof that they could not be completely burned with high efficiencies, *under proper conditions*, namely, those suited for fuels high in ash and fixed carbon, but low in their percentage of volatile matter.

The more careful study of the problems of fuel combustion in recent years has shown that practically every variety and type of combustible material can be burned, and its heat value converted into the thermal energy of steam, provided, first, that the combustible matter exceeds 65 per cent; second, that the furnace is correctly designed and, third, that the air supply is properly distributed and proportioned to the needs of the fuel. Materials which have for many years been regarded as waste trade-products are now being impressed into the service of the steam-producer, and the combustion of coke and coke-breeze is in reality a much simpler problem than the burning of *"Towns' refuse"* or of *"Bagasse"* and other vegetable wastes, for power purposes.

The technical side of the problem is only one aspect of it. In the past, the relative price of coal and coke has also had much to do with the neglect of the latter as a fuel for steam-boilers. The war has led to a considerable increase in the demand and in the price paid for coal, while the production of coke has been enormously increased, owing to the great demand for benzol, toluol, and other valuable by-products. In many coal and coke producing districts, therefore, the price of coke and coke-breeze has remained steady or has actually fallen, while that of coal has increased, and the relative values of coal and coke have been altered in favor of the latter fuel. It is highly probable that this altered economic relationship will continue after the war is over, for the increase in the labor charges of mines and railways is likely to be permanent, and coal will remain at its present high level of cost for many years to come. The following data and information concerning the use of coke and coke-breeze for steam-raising should therefore prove of more than passing value, since the conditions which favor the cheaper fuel are likely to continue.

THE CHEMICAL CONSTITUTION AND CALORIFIC VALUE OF COKE AND COKE-BREEZE.

Coke represents the non-volatile portion of ordinary coal after it has been subjected to heat in the absence of air, and it may be regarded therefore as containing only the fixed carbon and the mineral matter, or ash, of the original fuel. Nearly all forms of coke contain a small amount of volatile matter, varying from 1.0 up to 5.0 per cent, the percentage being lowest in the hard cokes produced by high-temperature ovens for blast furnace work. The soft porous cokes obtained by low-temperature distillation contain on the other hand from 5 to 10 per cent of volatile matter, and do not come within the scope of the present article.

Coke-breeze represents the screenings from the lump coke after this has been drawn from the retorts and has been quenched by water. It contains as a general rule a higher percentage of ash and moisture than the lump coke from which it has been obtained.

From the steam-raiser's point of view, therefore, the chief impurities of these forms of fuel are the moisture and the ash.

THE MOISTURE IN COKE AND ITS EFFECT UPON COMBUSTION.

Both coke and coke-breeze contain considerable percentages of mechanically held moisture, due to their physical structure and to the drenching practice. Contracts for either form of fuel should therefore specify a limit of 6 per cent for the allowable amount of moisture. The disadvantage of using coke or coke-breeze with higher percentages than 6 per cent is that this water has all to be converted into steam and driven off before the coke can be ignited. Furthermore, since it escapes in the form of aqueous vapor with the waste-gases, it carries off a large amount of latent heat which cannot be recovered even in the economizers. Experimental steam-raising trials of coke and coke-breeze containing varying degrees of moisture, by the Buenos Ayres Tramway Power Station, proved that a 10 per cent rise in moisture caused a 24 per cent increase in the fuel bill.

THE ASH IN COKE.

The ash in coke and coke-breeze varies greatly, since it represents all the mineral matter of the original fuel in a more concentrated form. If this original fuel has been a bituminous slack or coal of poor quality, the ash percentage in the coke or coke-breeze may rise to 20 or even 30 per cent. Lump coke of good quality however should not contain more than 6 to 10 per cent of ash, and contracts should have the latter limit inserted as the maximum allowable percentage.

Coke-breeze will naturally contain a higher percentage of ash, and up to 20 per cent may be expected to occur in the deliveries of this form of fuel. Should this limit be exceeded, the breeze should be rejected, for a fuel containing over 20 per cent ash and 10 per cent moisture will not yield much heat of value for power purposes when burned under steam-boilers.

The following are typical analyses of coke and coke-breeze, with figures for the gross and net calorific values, as determined by laboratory methods. It may be noted here that the calorimeter determinations of coke and coke-breeze will always yield considerably higher values than can be obtained in practice, owing to the fact that they are tested in the dry state. The necessary deduction that must be made for the heat

*The second of a series; the first paper on "Town's Refuse" appeared in our issue of Feb. 15, 1917; Vol. XVI, p. 229.

lost in drying the fuel is shown in column 4 of Table I, and is found by calculating the thermal units required to convert the water contained in one pound of the fuel into steam.

THE CONDITIONS OF COMBUSTION, AND FORMS OF FURNACE GRATE REQUIRED.

The above analyses show that coke and coke-breeze contain larger amounts of moisture and ash than ordinary coal, and that the percentage of fixed carbon in the combustible portion of the fuel approaches that of anthracite. The conditions required for the successful combustion and utilization of the heat generated by coke and coke-breeze are therefore similar to those obtaining with anthracite fuel, and are, first, artificial or forced draft; second, close approximation of the heat absorbing surface to the glowing mass of fuel; and third, facilities for dealing economically with the large amounts of clinker and ash. As the volume of hydrocarbon gas given off by the fuel is comparatively small, the need for large combustion spaces and for the supply of secondary air is non-existent, the conversion of the carbon into carbon-dioxide gas occurring chiefly on the bars of the grate.

For these reasons the marine, Lancashire, or Cornish type of boiler is more suitable than the water-tube boiler for burning coke and coke-breeze, and very little adaptation of the internally fired boiler-furnace is required to fit it for use with the new fuel. If it is desired to burn the coke or breeze on some form of mechanical stoker under a water-tube boiler, it is necessary to mix it with ordinary fuel. In the last section of this article some figures are given showing the economy of this method of burning. The maximum proportion of coke which can be burned in this way is 50 per cent, and where it is necessary or desirable to exceed this proportion, the grate and conditions of draft must be altered to meet the new requirements.

For use either alone or mixed with bituminous coal, the coke must be of small lump size (say 1 to 1½ in. cubes) and a fire-bed of not more than six to eight inches in thickness should be maintained. When burning a mixture of coal and coke, or coal and breeze, it is very important that the fuel should be well mixed, and in the case of lump fuel, that the pieces should be similar in size. A method of burning the mixed fuels on chain-grate stokers, which is stated to have given good results, is to fit an additional hopper to the front of the stoker by means of which a layer of small crushed coke or breeze is fed on the chain-grate, before the ordinary fuel comes down upon it from the hopper above. The grate then travels forward with two layers of fuel upon it, the coke below and the bituminous above. The proportionate depth of these two layers can be varied by altering the relative speeds at which the two hoppers deliver their fuel to the grate.

Since coke is not readily ignited except by contact with glowing carbon, the fires must be started with bituminous coal, and when the volatile gases have distilled off and only red-hot embers remain on the grate bars, the firing with coke can commence.

Since practically no hydrocarbon gases are evolved from coke on heating, the air admission may be entirely from below the grate, and all openings and grids by which secondary air has been admitted above the fuel or behind the bridge should be closed. As coke occupies twice the space of ordinary coal, weight for weight, it follows that twice the bulk of coke must be burned on the same grate-area in order to obtain the same evaporative effect. This rate of combustion demands in most cases *closed ashpits and forced draft.*

If breeze and lump coke are being burned together it is well to have transverse bars instead of longitudinal ones, since these check the tendency of the fine ash to be carried away into the side-flues of the boiler. When transverse bars are used in the furnace, however, they must be bedded in some refractory cement at the ends where they approach the boiler-plates—otherwise "blow-pipe" action may occur at these points, and the plates suffer injury.

As regards the rate of combustion possible with coke: When a good natural chimney draft exists, the rate of burning can be raised to 15 or 20 lb. per sq. ft. of grate area per hour. With forced-draft, the rate can be increased to 30 lb. per sq. ft. per hour. A grate area of 33 sq. ft. (that of the ordinary 7 ft. diameter Lancashire boiler) will thus suffice to burn 990 lb. of coke per hour. Assuming that 8 lb. of water are evaporated per pound of coke, the evaporative effect will be 7920 lb. of water per hour. Since the greater part of the evaporative effect under these conditions is obtained by radiation, i. e., by the heat transmitted directly through the boiler-plates in the neighborhood of the fire-box, it follows that in coke-fired Lancashire or marine type boilers, *special attention must be directed toward keeping these plates free from scale and grease.* The feed-water must therefore be regularly examined for scale-forming salts and organic impurities.

When coke-breeze or coke-ashes containing over 30 per cent of incombustible matter are to be burned alone, some form of external furnace of the Dutch-oven type becomes necessary for their complete combustion, and in this case the advantages offered by the internal fire-boxes of the marine and Lancashire type of boiler are lost. Forced-draft will still be necessary to burn the fuel, and the radiant heat from the furnace can be utilized by means of chequer work and hollow walls for pre-heating the air. The heat of the gases issuing from this type of furnace can be best utilized in the water-tube type of boiler. Underfeed stokers are sometimes used with this type of furnace, but as the proportion of ash in the fuel rises, the difficulty of obtaining anything like complete combustion of the carbonaceous matter with mechanical stokers increases.

With any type of hand-fired furnace, great care is required to avoid accidents from back-firing or from explosions in the boiler flues, due to the accumulation

of carbon monoxide gas when the draft is cut off for cleaning and clinkering the fires. In order to minimize the danger from these causes, the following precautions may be taken:

First, swivel-dampers should be substituted for vertical drop-dampers in the side-flues. These should be worked with link-rods and a lever from the boiler-front. The side-flues should be inspected and cleaned frequently, to prevent accumulations of flue-dust or soot at the foot of the swivel-dampers.

Second, an excessive depth of fuel-bed is contributory to the accumulation of explosive gases and a fire-bed of 10 in. should never be exceeded.

Third, the safety-plugs inserted in the ends of the flue-walls should not be blocked by heavy iron tools or implements, but should have a free path of egress should explosions occur in the flues.

Since the local temperatures in furnaces fired entirely with coke or breeze under forced draft are much higher than in ordinary coal-fired furnaces, some trouble also may be experienced by burning and failure of the fire-bars. If this occurs the admission of steam to the ash-pit under the grates may be the only practical remedy, unless some system of water-cooling be adopted. If steam-jets are used for creating the draft, this danger is already provided for—but where fan-draft is employed an emergency steam-pipe to each closed ash-pit is desirable.

The correct regulation of the air supply to coke-fired boilers is not more difficult than that to coal-fired, but there is no smoke to warn the firemen when the air supply is deficient. With both types of fuel constant testing of the waste-gases is an essential of good management and of high efficiencies. Under scientific management, however, it is possible to obtain a higher average percentage of CO_2 in the waste gases with coke than with ordinary bituminous coal. This means that the chimney losses are reduced considerably, and that a higher efficiency is obtained from the fuel. A clear chimney gas is a considerable advantage, especially in those industrial centers where the smoke-inspector is active, for under no conditions of neglect can coke-fired boilers produce a black smoke.

ACTUAL RESULTS OBTAINED WITH COKE AND COKE-BREEZE FIRING

Test I.—For some months a small electrical supply station in the north of England has been successfully employing a mixture of slack and coke-breeze in equal proportions upon a chain-grate stoker, with a water-tube boiler. The slack costs $4 per ton at the generating station, while coke-breeze from the local gas works can be delivered at a cost of only $1.50 per ton. The average price of the mixed fuel per ton as charged into the hoppers of the chain-grate stoker is therefore $2.75 per ton. The day load at this station is taken by a Diesel oil engine, and the boiler is only worked in the evening. The results obtained with the two fuels are:

	Slack Alone	Mixed Fuel
Date of test	Nov. 13, 1914	Oct. 10, 1916
Duration of test	4 hours	4 hours
Calorific value of dry fuel in B.t.u.	13,168	12,178
Price per ton in the works	$4.00	$2.75
Moisture in fuel	7.68 per cent	10.09 per cent
Lb. of fuel used	4,027 lb.	4,704 lb.
Lb. of water evaporated	31,531 lb.	30,800 lb.
Water evaporated per lb. fuel	7.83 lb.	6.55 lb.
Draft	½ inch	½ inch
Cost of evaporating 1,000 gallons of water	$2.26	$1.86

This shows a saving in fuel costs of 40 cents per 1000 gal. of water evaporated, or 18 per cent in favor of the mixed fuel. It is noteworthy that the draft was the same in both tests, and that the total output of steam was only slightly less with the coke-breeze mixture.

Test 2.—The engineers of the Buenos Ayres Tramway Power Station have made a large scale trial of gas-coke and coke-breeze for firing their boilers, and have allowed Messrs. Beatty and Smith to publish the results obtained, in the paper named below.[1]

Ten thousand tons of gas coke were burned during the trial, containing on the average 13.5 per cent ash and 13 per cent moisture. The following are the average results obtained from the fuel:

Water evaporated per lb. of fuel	5.7 lb.
Water evaporated per lb. of fuel from and at 212 deg. F	6.71 lb.
Fuel used per kw.-hr	3.675 lb.
Boiler efficiency	57.6 %

As the cost of the gas coke is not given, the comparative costs of firing with coal and coke cannot be calculated, and in this respect the results are not so useful as those given in the preceding table. The best results at Buenos Ayres were obtained with a large delivery of coke which contained only 6 per cent moisture. This gave an evaporative effect of 7.9 lb. water (from and at 212 deg. Fahr.) per pound of fuel, during trials extending over one month, corresponding to a boiler efficiency of 62 per cent.

When the moisture in the coke rose to 20 per cent, the boiler efficiency fell away to 55.6 per cent. As already stated, a 10 per cent rise in the moisture content of the coke caused a 24 per cent increase in the weight of fuel used, for not only had more coke to be handled to obtain the same amount of combustible, but a greater portion of the heat generated was employed in evaporating the water.

Test 3.—The chief engineer of the London Coke Committee, in a paper read before the London District Gas Association, has given the results of comparative tests made when firing coal and gas coke in two Cornish boilers in February of the past year.[2]

The tests were made in London, which accounts for the fact that the relative prices of coal and coke-breeze are much higher than in Test I, and that the saving effected by the use of the cheaper fuel rises to 34 per cent. The substitution of forced draft for natural draft, and the maintenance of a high CO_2 average, would no doubt account for the marked increase in the efficiency of the boilers.

The author of the paper from which this data was obtained exhibited models of the steam-jet draft apparatus used in these tests, and stated that the steam used for the jets did not exceed 3 per cent of that generated. He emphasized also the fact that the heat generated by coke is chiefly utilized as radiant heat in the boiler, and that, for this reason, the fire-box heating-surface was the chief factor in steam production.

The tendency on American railways, where mechanically stoked coke-breeze was being employed for steaming purposes was, he stated, to increase the area of the fire-box heating-surface and to diminish that of the tubes. Reliable tests had proved that 1 sq. ft. of fire-box heating-surface, when exposed to direct radiation

FUEL TEST, FEBRUARY, 1916

Fuel Tested	Bituminous Coal	Gas-Coke	Gas-Coke and Coke Breeze
System of Draft	Natural Draft	Blowers	Blowers
Cost per ton delivered	$6 00	$6 00	$4 20
Duration of trial, hours	6 50	7 25	7.66
Total grate-area, sq. ft	58	58	58
Amount of fuel used, lb.	6,720	7,500	4,200 coke + 4,200 breeze
Fuel burned per sq. ft. of grate area per hr., lb.	16 1	16 1	17 1
Water evaporated, lb. actual	45,950	65,600	39,200
Water from and at 212 deg. F. per lb. of fuel	7 74	9.80	7.99
Cost per 1,000 gals. evaporated	$3 48	$2 80	$2.26
Per cent CO_2 in gas	Not taken	16 0	16.25
Net efficiency of plant, per cent	70 72	85	80.9
Financial saving effected by adopting coke-fuel and forced-draft, per cent.		19	34

from burning coke, will evaporate five times as much water as 1 sq. ft. of tube-surface.

Test 4.—German tests with coke and coke-breeze. In the year 1910 a commission was appointed by one of the leading German societies of mining engineers to investigate the utilization of low grade fuels, and the reports issued by this commission have been published from time to time in the German mining journal *Glückauf*. Some of the figures and results obtained by this commission will now be quoted:

Two evaporative tests were carried out on Aug. 2, and 3, 1910, at the Consolidation mine, near Dortmund with the "*Praesto*" and "*Kridlo*" systems of firing coke-breeze or ashes from the quenching-plate containing 24 per cent ash, 15 per cent moisture, and 4.5 per cent volatile matter. The boiler with which this test was made was one of a battery of six "Alban" type of water-tube boilers, with a grate surface of 32 square feet, and a heating surface of 1393 sq. ft. The fuel used cost only 40 cents per ton. Each test lasted 8 hours, and after deducting the steam used for the steam jets, the tests showed that the evaporation per pound of fuel had been 3.03 lb. in one case and 3.3 lb. in the other. These results show, on comparison with those obtained with a similar fuel burned under the same conditions under a Lancashire boiler, that the water-tube type of boiler is not so suitable as the other for use with a fuel so low in volatile matter, thus confirming what was said in the introduction on this subject.

Further tests made with a similar fuel, and the same systems of firing, were made on Aug. 25, 26 and 31, 1910, at an installation of Lancashire boilers located at the Ludwig mine, Westphalia. The coke-breeze in this case contained 10 per cent volatile matter. The grate area was 31 sq. ft., the heating surface was 1003 sq. ft., while the forced draft was obtained from an electrically-driven fan. The results of three tests showed that 5.2, 4.90 and 4.64 lb. respectively of water had been evaporated per pound of fuel burned, and that the cost of evaporating, after allowing for all running and fixed charges, had been from 78 to 82 cents per 1000 gal. of water.

Some figures obtained by the same commission at the Achenbach mine with coke and coke-breeze burned by aid of the "Wilton" apparatus for producing forced-draft are as follows:

Three steam-jets were used to force the air into the furnace, and a special form of distributing box was employed to carry the air up through the furnace bars into the bed of burning fuel. The steam-jets were not employed continuously, but were closed for about one-fourth of the time when the fires were being cleaned, or fresh fuel was being charged. A separate test was made of the steam required to produce the blast, by allowing a similar steam-jet to blow through a cooling-worm, and by weighing the water condensed. This amounted to 164 lb. per hour for the first test, and to 125 lb. per hour for the second test, and represented about 3 per cent of the steam production of the boiler. Comparative tests were made in September and November, 1912, with the natural draft and forced draft systems, and the following are the more important average figures obtained in the four trials, the test in each case lasting eight hours:

	Natural Draft	Forced Draft
Cost of fuel per ton	38 cents	38 cents
Water evaporated per lb. of fuel	4.08 lb.	4.99 lb.
Water evaporated per sq. ft. of grate area per hour	20.50 lb.	36.70 lb.
Cost of evaporating 1,000 gals. of water	88 cents	75 cents
Boiler efficiency	52.4%	65.8%

The special feature of these German tests is the very low cost of the fuel used, and consequently the very economical figure for the cost of evaporating 1000 gal. of water, namely 75 to 88 cents, as compared with $1.86, the lowest cost for the English returns. When comparing the figures, however, we must note that the German tests were made at the mines or coke-ovens, *with fuel which would have otherwise been wasted*, and that the charge made for it to the boilers was merely a nominal one.

With coke-breeze at the same cost, the English figures for the cost of evaporating 1000 gal. of water would prove equally striking.

Synopsis of Recent Metallurgical and Chemical Literature

Cellulose

Cellulose and Related Products.—In the *Journal of the Society of Chemical Industry* for May 31, 1917, is given an abstract of a lecture by C. F. CROSS, delivered at the Royal Institution on March 2, 1917. The lecture covered the chemical and industrial developments of the cellulose and allied industries from 1866 to 1916. The "positive" chemical technology of cellulose is necessarily based upon its reactivity, and the industries which exploit the reaction changes of cellulose are of widely divergent character; those of Group A are based upon reactions of decomposition, those of Group B are based upon the properties of synthetical derivatives.

Of Group A, the resolution of cellulose into sugar (dextrose) by acid hydrolysis is the basis (1) of a process for the preparation of industrial (ethyl) alcohol from wood, and more economically from wood wastes. According to our latest information, the technical difficulties presented by this apparently simple process have been so far overcome that the alcohol is produced on the large scale at a cost of 2½ d. per gallon, exclusive of the small cost of the waste wood material. Under these most favorable conditions, however, the yield of alcohol is only 5 per cent of the weight of the wood substance, or say 8 per cent of its cellulose content, leaving therefore a very large item of final waste to the debit account of the chemist.

(2) Sawdust, or other wood waste, fused—*i.e.*, heated at high temperatures—with the caustic alkalies is destructively oxidized, and the main product of the oxidation is oxalic acid; this process is in effect the main source of the acid, as an industrial product.

(3) Waste wood subjected to destructive distillation in closed retorts is resolved into gaseous and volatile liquid products, with a solid residue of charcoal or pseudo-carbon. The liquid products contain acetic acid, acetone, and methyl alcohol as chief constituents, and have been the main source of supply of these chemical individuals, which, as reagents especially, are indispensable in modern chemical industry.

In this direction, however, cellulose material and its wasteful treatment by destructive distillation are being supplanted by a direct and controlled synthesis from calcium carbide, acetylene being quantitatively transformed into acetaldehyde, and this into acetic acid. In this new industry the pioneers in this country are the British Cellulose and Chemical Manufacturing Company, Spondon, Derby.

(4) Cellulose treated in full contact with oxygen is burned with the familiar flame combustion; but from all the natural structural forms there is a residue of inorganic matter (ash) which when present in impotrant proportion preserves the general structural details of the original. This intimate combination of cellulose with inorganic matter is a characteristic property of colloids of which cellulose is the prototype. It is the basis of innumerable processes incidental to the dyeing and coloring of cellulose fabrics and tissues. But the production of a combustion skeleton for utilization as an industrial product is a modern and noteworthy realization of a primary cellulose quality "strong even in death."

The familiar incandescent gas mantle is the skeleton of a textile material impregnated as such, or as we may say, "in the flesh," with colloidal thorium and cerium oxides, and afterwards cremated.

Of the cellulose industries of Group B, those (1) based on the nitric esters are of preponderating importance, for they include the production of the modern military explosives and they connote developments in pure and applied science peculiarly characteristic of the age. Cellulose nitrate not only fulfills the ideal of chemical effect, *i.e.*, total conversion of solid into gaseous matter, at maximum increase of volume (or pressure), further increased by the temperature of combustion, but is a stable form of this high chemical potential, and further owing to its colloidal plastic properties can be molded into any desired form and is therefore able to meet the most exacting specification of ballistic requirements. There is no doubt that mankind is directly indebted for its "smokeless" powders and the basis of the vast developments of modern military power to the pioneer work of Alfred Nobel and his collaborators.

The lower degrees of "nitration" of cellulose are represented by products which are the basis of "celluloid," and the celluloid industries connote the production of a large number of familiar objects both useful and ornamental, and a progressively increased production from the date of the pioneer work of the American inventor, Hyatt (1869).

Celluloid realizes a very high order of plasticity, and it is this structural potentiality which enables it to maintain its industrial leadership in spite of its disadvantages of hgh inflammability frequently and tragically manifested.

(2) The analogues of the nitric esters are the acetic esters of cellulose derivatives, which are necessarily colloids with plastic capabilities, water-resistant as are the nitrates, and with a higher order of resistance to heat (unchanged at 200 deg. C.), and the ordinary inflammability of organic substances. Important uses of the cellulose acetates already established are: (*a*) in aeroplane construction, for treating to render taut and impermeable the textile fabric which constitutes the air-resistant surface of the wings; (*b*) in the form of film, as the "emulsion-film" support in photographic work, notably for the preparation of the continuous cinema picture; (*c*) for a varnish for metallic surfaces, and notably for electrical insulation and applications which depend upon exceptionally low inductive capacity.

In the above brief account of the cellulose nitrates and acetates there is the implicit suggestion of the production of artificial textile threads by drawing the solutions of these bodies through orifices of suitable form and dimensions such that after removal of the solvent liquid the re-solidified and structureless ester constitutes a cylnder of hyaline material of uniform diameter.

The industrial production of artificial threads, and notably of the "silk" or lustra cellulose, we owe to the pioneer enterprise and purposeful tenacity of a French technologist, H. de Chardonnet. But cellulose nitrate as *matière première* has many and obvious defects; hence the alternative plastic forms or derivatives of cellulose have progressively displaced the original industrial product, which had a brilliant career of success in the early years of this century.

There are three main rival processes of which the underlying principles are common. They are expressed in the stages or phases of the process:

(1) Cellulose is transformed by reaction into a synthetic derivative—dissolved as such to an 8 per cent solution (calculated as cellulose), filtered and continuously projected, or drawn through fine tubes or orifices, into a solidifying or setting medium.

(2) The thread as a unit filament (monofil, crin, crinole), or multiple group of twisted filaments (artificial silk), is a cellulose ester or other derivative, and is chemically treated to remove combined groups, or impurities as by-products of decomposing reactions; the thread substance is cellulose, reappearing as such after the cycle of changes.

The three cellulose derivatives on which these important industrial processes are based are: (1) The nitric esters; drawn or "spun," as ether-alcohol solution (Chardonnet process).

(2) The ammonia-soluble cellulose-hydrate-copper-hydroxide compounds (cuprammonium process).

(3) The xanthic or sulpho-carbonic ester, synthesized in two stages: (*a*) mercerization of the cellulose; (*b*) combination of the alkali cellulose with carbon bisulphide, and solution of the product in water (viscose process).

Of these the viscose process is now predominant by reason of its advantages, technical and economic. It will be noted that the material "elements" of the industry are cellulose, common salt, carbon and sulphur, than which no simpler terms could be devised, even as *a priori* proposition.

Of other industrial applications of the Viscose

process, the production of transparent film in continuous length is a variation only of the process above described, the liquid viscose being drawn through a controlled adjustable slit of 1.5 m. width, into a setting solution or precipitant, which converts it at once into the solid state, but retaining 80 per cent of water. This hydrated product is purified by successive treatments, and is finally dehydrated and dried with a shrinkage of 33 per cent, the 1.5 m. of hydrated xanthate, as first precipitated, being reduced to a width of 1 m. in the finished cellulose film.

This is a noteworthy achievement in chemical engineering, and is entirely due to the inventive presistence of the personnel of the Société Française de la Viscose, especially to MM L. Naudin and J. E. Brandenberger. It is a pleasant duty to recognize technical pioneer work of so high an order.

In addition to these main applications there are many other uses of the reactions involved in the viscose cycle. Thus "mercerization" of cellulose is an application of the interaction of cellulose (textiles) and caustic soda, to produce luster effects and finishes upon cotton goods. The structural changes of yarns and cloths determined by these reactions were investigated by John Mercer at a period which long antedates our half-century of progress. To Mercer's anticipations there succeeded a long incubation period. A few discoveries of minor import in this field then revived interest in the major product; the alkali cellulose of the Viscose cycle and "mercerized goods" became a textile market of first note and importance.

Copper, Lead and Zinc

Electric Smelting of Copper Ores.—W. DEWAR, in the June, 1917, number of the *Mining Magazine*, describes the results of two tests when smelting highly silicious oxidized copper ores in the electric furnace. These tests were run at the works of Messrs. Keller, Leleux & Company, at Livet, Isere, France. The furnace used was of the resistance type consuming 600 to 700 kilowatts alternating current. The furnace had two tap-holes, one for the metal and one for the slag. The ore was crushed to pass a 1-in. ring; the flux was lime and the reducing agent was charcoal. The ore used contained 10.94 per cent CuO in the first test, and 12.10 per cent in the second. The summary of results is given in Table I:

In test No. 1 the voltage varied from 96 to 106, and the amperage from 2400 to 5500; in No. 2 the voltage variation was from 97 to 104 and the amperage 3500 to 6000.

The slags formed were bisilicates, the respective amounts formed per ton of ore smelted being 1.22 and 1.24 tons, and averaging 0.25 per cent and 0.3 per cent in copper. These slags compare favorably with those obtained in matte smelting and show a decided improvement over slags obtained in blast-furnace smelting of such ores; they were clean and flowed freely, usually solidifying without previously passing through a plastic state. The average running temperature was 1450 deg. C., as determined with a Wanner pyrometer.

With a suitable slag there is no difficulty in producing a good grade of black copper in the electric furnace. No metal was tapped in the first trial due to the fact that the tap-hole for metal was too high. In the second test three tappings were made 9 hours, 21 hours and 31 hours after starting. The analyses were as follows:

	1	2	3
Copper	75.96%	61.25%	57.74%
Iron	23.60%	34.75%	39.90%

Toward the end of the run, this metal was thrown back in the furnace and remelted with that remaining in the furnace, and then tapped off into specially designed molds in order to separate the metal into a high and a low grade product. It was found that segregation takes place at certain as yet undetermined limits, two segregates being obtained, one running 91 per cent copper and one 51 to 57.6 per cent copper.

Physical Chemistry

The Motion of Ions and Electrons Through Gases. by E. M. WELLISCH, University of Sydney, *Philosophical Magazine*, Sixth Series, No. 199, page 33. It has long been known that in air at very low pressures the current of negative electricity is due practically entirely to free electrons; at higher pressures, however, it is due to the motion of negative ions. If the ion at high gas pressure be conceived as a cluster of molecules, it would follow that as the pressure was reduced the average number of molecules in the cluster would decrease; as the pressure was still further reduced, and individual negative carrier would be for part of the time in the ionic state (say now as a single molecule) and for the remainder would exist as a free electron. Ultimately at very low pressures the carriers would be all free electrons. New experiments described in the paper show that while the law pk = constant (where k is the mobility of the ion, p the pressure of the gas) holds good to the lowest pressure for the positive ion, the negative carriers were found to consist of two distinct kinds, electrons and single-molecule ions, the former coming more and more into evidence as the pressure of the gas was reduced. The electrons travel freely through the gas without attaching themselves to molecules. When the ions were consid-

TABLE I—SUMMARY OF RESULTS. LONG TONS

ered apart from electrons all previously noted anomalies disappear, the velocity being expressible in the form

$$v = k_v \frac{x}{p}.$$

In the so-called permanent gases free electrons will therefore occur at all pressures, even if a very small relative number. In inert gases the negative carriers are almost entirely electrons even at atmospheric pressure, but in all instances a slight trace of impurity (especially oxygen) was sufficient to convert the carriers into ions. Inert gases and hydrogen are now regarded as being exceptional, not in their power of containing free electrons, but by reason of their great reluctance to form negative ions, *i.e.*, by reason of the exceptionally large proportion of electrons to ions. It would seem probable that in order to supply an appreciable number of negative ions, the molecules must contain atoms either of oxygen or chlorine, bromine or iodine. An explanation for this is advanced that an electron cannot effect a permanent union with an uncharged molecule to form a negative ion unless the relative velocity at collision exceed a critical value characteristic of the molecule concerned, which value is reduced by oxygen and halogen atoms.

The difference in mobility of the positive and negative ions in a gas is ascribed by the author to a difference in the attractive forces between each kind of ion and the uncharged molecules and their elastic properties. If the law of impact is different between the molecules of the gas and the positive and negative ions respectively, it follows that the rate of diffusion of the two sets of ions will in general be different. The general effects can be accounted for by two considerations: firstly, the discrete nature of the electronic charge, and secondly, the assumption that the positive and negative charges are differently distributed in the respective ions.

The Nature of Chemical Affinity. By W. M. Thornton, Armstrong College, Newcastle-upon-Tyne. *Philosophical Magazine*, Sixth Series, No. 199, page 66. In the absence of any knowledge of how an electron, acting as a bond, is anchored into the atomic structures of the combining atoms, the force that a bond sustains is assumed to obey the usual laws of attraction, and to be proportional to the masses of the molecules. In an explosive mixture before ignition, molecules collide without liberation of heat; but when activated in the explosion-wave front they combine with increased kinetic energy of which the heat set free is a measure. Formulæ are developed on the basis of these ideas, showing that, if true, the ratio $\frac{H^2}{m_1 m_2} = k$, where H is the total heat contained in the products of combustion, m_1 is the mass of the combustible molecule and m_2 is the mass of oxygen burned. The assumptions made above are substantiated in a study of the heats of combustion of a large number of compounds whose end products are steam and CO_2, from which $k = 38.6$, within limits. Hydrogen and CO are not reduced to the same products and their affinities are not comparable in terms of heat of combustion. For this reason it is impossible to compare the affinities of elements thermally, and heats of oxidation of metals differ widely. It is clear that affinity is not a simple electrostatic attraction, and that between elements it is dependent upon atomic formation.

Nitric Acid

Explosibility of Acetone-Air Mixtures.—On investigating the industrial conditions under which the vapors of inflammable liquids form explosive mixtures with air, Drs. R. V. Wheeler and A. Whitaker deal, in the account of their first research presented to the Chemical Society, with acetone, according to the *Chemical Trade Journal and Chemical Engineer* for July 14, 1917. This material is largely used in cordite manufacture, and rapid air currents may pass through long mains charged with acetone vapors. Laboratory methods have so far been used, because acetone vapor being soluble in water, glycerol, brine, etc., the vapor-air mixture must be stored over mercury, and the apparatus must be kept thoroughly dry. Experiments on the higher and lower limits of inflammability of the mixtures were made in tubes 2.5 cm., 5 cm., 10 cm. in diameter and 60 cm., 150 cm. and 75 cm. in length, for horizontal, downward and upward propagation of flame. When the diameter exceeds 5 cm. the pipe size influences the inflammability limits little, and it is concluded that the lower and higher limit would, for horizontal propagation in large pipes of about 60 cm. diameter, be 2 per cent and 10 per cent of acetone vapor. The speed of flame propagation was determined for the "uniform movement" of the flame, though it is known that this uniform movement is only observed in tubes of small diameters. In the 2.5-cm. tube this speed attained a maximum of 96 cm. per second in mixtures containing 5.5 per cent of acetone. For pipes of 30 cm., 60 cm. and 96 cm. diameters these speeds would probably be 2.5, 3 and 3.5 times as great. The quantity of acetone required for complete combustion of the oxygen in air would be 4.76 per cent.

Recent Metallurgical and Chemical Patents

Hydrometallurgy of Copper

Production of Trioxychloride—A patent for refinements of an earlier method has recently been issued to Charles S. Bradley, of New York City, in which crushed ore is heated with access of air to a temperature of 450 deg. to 550 deg. C., and thus subjected to an amphidizing treatment already patented (No. 1,011,562). The reactions vary with the ore and treatment, but the copper reverts to sulfate, containing some unaffected sulfide, some oxide and metallic copper, while the iron is mostly converted into ferric oxide, with some ferric sulfate. This roasted ore is then digested with a hot solution of calcium chloride, when the copper enters as soluble chloride, precipitating equivalent quantities of lime, thus:

$$CuSO_4 + CaCl_2 = CuCl_2 + CaSO_4$$

The cupric and other chlorides maintained in the solutions operate as secondary solvents for a number of the remnants which are insoluble directly in the calcium chloride solution. Sulfuric acid, mainly from the SO_2 in the dust and fumes, produces hydrochloric acid with the calcium chloride and any copper oxide present in the amphidized mass is converted by the hydrochloric acid into copper chloride. Metallic copper and copper sulfide react with cupric chloride forming cuprous chloride, the

sulfur of the sulfide being thereby set free and precipitated:

$$Cu + CuCl_2 = Cu_2Cl_2$$
$$CuS + CuCl_2 = Cu_2Cl_2 + S$$
$$H_2SO_4 + CaCl_2 = CaSO_4 + 2HCl$$
$$CuO + 2HCl = CuCl_2 + H_2O$$

Oxygen is supplied to the system at various points, so that this cuprous chloride is converted into oxychloride of copper which reacts with further quantities of hydrochloric acid, produced as described above, to form further quantities of cupric chloride. It should also be noted that the copper chloride is further maintained in the cupric state by the action of the iron chloride formed from ferric remnants in the solution apparatus.

$$Cu_2Cl_2 + O = Cu_2Cl_2O$$
$$Cu_2Cl_2O + 2HCl = 2CuCl_2 + H_2O$$

The mass is now filtered, and the solution carrying the values is subjected to further oxidation in order to insure that the values will all be combined at their highest valence and to prevent the formation of insoluble cuprous salts during subsequent treatments. A portion of the solute is now treated with sufficient cupric oxide, $Ca(OH)_2$ or $CaCO_3$ to precipitate all the iron and aluminium contained, and then the copper content thrown down as trioxychloride by $CaCO_3$, with the regeneration of the reagent, calcium chloride.

$$4CuCl_2 + 3CaCO_3 \quad CuCl_2 3CuO + 3CaCl_2 + 2CO_2$$

That part of the solution which was not so precipitated is used as a medium for absorbing the dust and fumes from the roaster, as described in the former patent. The presence of iron and aluminium salts, especially the iron, in the solution is desired as they are useful in this absorption, and also play an important part in taking values into solution. Furthermore it is desirable to retain a portion of the cupric chloride in the solution for reasons already apparent. These absorbing solutions are again oxidized and reintroduced into the normal cycle.

It will be seen that the carrier solution loses a small amount of chlorine in the above process, which can be conserved by a conversion of all the copper into cupric oxide, as follows: The trioxychloride after it has been filtered out from the carrier solutions may be treated by a number of chemical substances which will react so as to produce a soluble chlorine compound; for example, sodium hydroxide, sodium carbonate or bicarbonate of soda. Preferably, however, the trioxychloride is treated with a suitable calcium compound so as to restore chlorine to the system as calcium chloride. The treatment may be conducted at more elevated temperatures when a dry method is preferred or if a wet method is deemed more suitable the reaction in such cases would take place in the neighborhood of 100 deg. C.

The trioxychloride is brought into association with calcium oxide in water at about boiling temperature, whereupon the calcium unites with the chlorine forming calcium chloride and the copper unites with the oxygen forming cupric oxide. The cupric oxide being insoluble immediately precipitates out while the calcium chloride goes into solution in the water. It should be noted that the reaction referred to takes place more readily in dilute solutions. After removing the cupric oxide the calcium chloride solution may if desired be evaporated, which operation can be carried on in metal vessels as the solutions are alkaline and hence not active to the common metals. The main reaction is

$$CuCl_2 3CuO + CaO = 4CuO + CaCl_2.$$

The cupric oxide is removed from the solution by filtration. The calcium chloride solution may be introduced into the reaction or dissolving drum in the first portion of the process for repeating the cycle of operations. (1,236,046, Aug. 7, 1917.)

Electro-Osmosis

Tanning by Electricity.—A process for tanning and impregnating materials according to the principles of electro-osmosis is patented by Botho Schwerin, of Frankfort-on-the-Main, Germany (assigned to Elektro-Osmose Aktiengesellschaft of Berlin, Germany). As applied to tanning hide with tannin, the process is as follows: (The hide is assumed to have been plumbed with lime.) In Fig. 1 *A* is a rectangular ves-

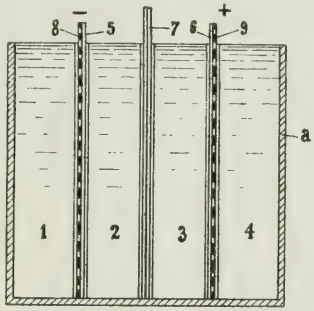

FIG. 1—SECTION OF TANNING APPARATUS

sel, subdivided into 4 compartments, by the diaphragms 5 and 6. The middle compartment is further subdivided into compartments 2 and 3 by the hide 7 which is stretched in a frame either directly or with use of a support. Behind the diaphragms are arranged perforated poles 8 and 9, in contact with the diaphragms. The latter may consist of a cellulose preparation, like parchment paper or viscose. The cathode chamber 1 and the anode chamber 4, are filled with water, which, in order to avoid resistance, preferably contains traces of caustic soda in the cathode chamber and of sulfuric acid in the anode chamber. In the anodic middle chamber there is water, in the cathodic middle chamber a dilute acid suitable for de-liming hide. When the electrodes are connected with the poles of a source of electric current, the hide is first purified in that the lime and other basic residues migrate out of it and pass into the cathode chamber through the feebly negative diaphragm. By this treatment the hide is caused to fall, and at the same time to become gradually of stronger electro-positive character. The first stage of the treatment is at an end when the de-adsorption of the basic residues is complete.

The tanning liquor is now charged into the chamber in front of the cathode. By the action of the electric current those cathodic constituents which could hinder the osmosis migrate through the cathodic diaphragm. On the other hand, the negative ions which prevent or limit the migration of the tannin migrate first through the hide and then into the anode chamber through the indifferent diaphragm. Proportionally to this progres-

sive purification of the tannin liquor, the solution of the tannin migrates through the hide and appears in the middle chamber 3, whence the solution is withdrawn. After it has been replenished it can be used again. This has the advantage that the longer the tanning liquor is used the purer it is. The anodic diaphragm must have such a potential that the actual ions can migrate through it, while the tannin cannot. If pure tannic acid solution, which contains no ions that can hinder osmosis, is used from the beginning, the hide need not be stretched in the middle chamber, but merely suspended therein. Circulation of the tanning liquor by stirring is then permissible.

If an impure tanning liquor contains acid residues, the osmosis of the tannin solution will not occur until the acid residues have passed the hide in order to be separated by the anodic diaphragm. If now by stirring the acid residues are again brought around to the cathode side, the migration of the tannin solution and therefore the tanning will be more or less delayed. So also basic residues which are brought by stirring to the anode side of the hide, act to diminish the electric charge of the hide by the back-migration, and this is obviously accompanied by a delay of the migration of the tannin. In impure tannin solutions, therefore, the hide must be stretched. (1,229,150, June 5, 1917.)

Electro-Osmotic Purification Process.—A process for removing suspended or colloidal matter from clay mixtures is patented by Graf Botho Schwerin, of Frankfort-on-the-Main, Germany (assigned to the Gesellschaft für Elektro-Osmose, of Frankfort-on-the-Main, Germany).

In an agitating tank the clay substance is suspended in water to form a thin mixture and to this is added a small proportion of a suitable electrolyte, such as sodium hydroxid. The suspension is run into one or more vats or basins and when there are several vats or basins the arrangement may be such that the liquid flows through them in series by means of conduits and the time during which the liquid is to remain in each may be selected as desired. From one or several vats the suspension is now conducted through pipes controlled by valves to an osmose apparatus, that is to say, an apparatus wherein the suspension is subjected to the action of an electric current. The character of the final product is determined by the concentration of the suspension between the electrodes of the osmose apparatus, the speed of the current and the nature of the added electrolyte, as well as by the strength and tension of the electric current. (1,229,203, June 5, 1917.)

Fused Silica

Fused Silica Articles.—Israel Rosenblum of Swampscott, Mass., has patented a method of producing articles of fused quartz in an atmosphere of nitrogen in graphite crucibles. The method is based upon the discovery that if a transparent quartz tube is slipped over a graphite rod and heated to a temperature between 1400 degrees centigrade to 1600 degrees centigrade in a nitrogen atmosphere, a compound of silicon, nitrogen and carbon is formed which acts as a protective coating over the graphite rod and prevents further action on the graphite by the quartz. As the melting point of the compound of silicon, nitrogen and carbon when once formed is far above the temperature needed to render the quartz plastic, which is about 1800 degrees centigrade, it follows that this compound acts as a protective layer, not permitting the quartz to be contaminated by the graphite. In practice illuminating gas may also be used. (1,229,324, June 12, 1917.)

Alloys

Iron-Chromium for Thermocouples, etc.—Alloys of iron, chromium and a small percentage of manganese for various purposes are patented by Albert L. Marsh of Detroit, Mich. (assigned to the Hoskins Manufacturing Company of Detroit, Mich.). The alloy is stated to be particularly useful for thermocouples or protecting tubes to be used in measuring the temperature of molten metal, particularly brass, at relatively high temperatures. The composition is approximately 25 per cent chromium, 2 per cent manganese and the balance iron. (1,229,770, June 12, 1917.)

Peat as a Reducing Agent in Smelting.—Nils Testrup of London, England, and Thomas Rigby of Dumfries, Scotland, have patented a method of utilizing peat as a reducing agent in smelting. The disadvantages of using peat are claimed to be overcome by using the Ekenberg process,

"known as wet carbonization, which consists in heating the peat under pressure sufficient to prevent ebullition to a temperature of about 180 deg. C., until its water binding properties are destroyed. Having thus been treated, the peat can readily be de-watered by filter-pressing, which produces press cakes suitable for use as the reducing agent, when directly added to the furnace charge, or after having been further dried and converted into briquets, which are then added to the charge.

"In this way, preliminary coking hitherto usual is rendered unnecessary, as it takes place in the furnace itself, while the hardness and crushing strength of the coke thus produced from the filter press cakes is equal to that of the best wood charcoal, and that from the briquets equal to the crushing strength of the best smelting coke, with the result that such coke is able to carry the weight of the charge.

"In carrying the invention into effect, as applied to smelting iron ore in a shaft furnace of the type described in Patent No. 1,106,166, the peat is heated to a temperature of about 180 deg. C., in a carbonizer of the well-known concentric tubular type, under pressure sufficient to prevent ebullition, until the water binding properties of the peat have been destroyed, whereupon the material is subjected to filter pressing, which results in the production of filter press cakes having a water content of about 70 per cent. To the furnace charge, consisting of iron ore and limestone, the filter press cakes are added, either as such, or as briquets formed after drying the material until its water content is about 5 per cent. In gradually descending therethrough the peat becomes coked by the hot uprising gases from the hot zone, while the products of destructive distillation pass off with the shaft gases at the top of the shaft, and are treated for recovery of nitrogen and tar, preferably by introducing the gases into the foul main of an ammonia recovery gas producer if, as often occurs, such is used for power, and fuel gas generation in the plant and which latter may conveniently also be supplied with peat press cake, briquets, or a mixture thereof.

"An intimate mixture of the furnace and producer gases results in such an event and the combustible value of the latter is consequently enhanced.

"We have observed that the temperature of coking the material in question is less important as affecting the strength of the product than the pressure employed in forming the cake or briquet, and consequently low coking temperatures such as prevail in the shaft can be used, and a high nitrogen recovery obtained. (1,233,144, July 10, 1917.)

Reorganization of Washington State College.—Reorganization of the Washington State College, here, will give a prominent place to the School of Mines, making the school one of the eight schools or colleges of the institution. Prof. Francis A. Thomson, head of the mining department, will become Dean of School of Mines.

The Greaves-Etchells Electric Furnace

By E. Kilburn Scott, A.M. Inst. C.E., M.I.E.E.

Since the war, one of the most striking developments of the steel industry of Great Britain has been the rapid increase in the number of electric steel furnaces. So successful have they been that the prejudice against this type of furnace is rapidly disappearing, and the change will probably rank as the most radical one in steel metallurgy since the time of Bessemer.

Among factors which have helped to bring the electric furnace into favor are the following:

(a) The war-demand for special tool steel for tools, dies, gages, etc.

(b) The demand for chrome and other special alloy-steels for aircraft tubing, and other high strength parts.

(c) The difficulty of obtaining Swedish iron, which besides being scarce, is extremely expensive.

(d) The difficulty of obtaining skilled labor to work the crucible steel process.

(e) The necessity of using turnings, millings, ends of tubes, bars, and other scrap steel.

(f) The ease with which high-class steel can be made from second grade materials.

For these reasons, furnaces of many well known types are now in operation in Great Britain, including the Heroult, Girod, Snyder, and Gronwall. Another furnace, which has met with considerable success, is that of Greaves-Etchells. As this is an all-British production both in inception and manufacture, a detailed description will be of interest. It is designed to operate on a three-phase or a two-phase supply, and in the former case has two of the phases connected to electrodes above the bath, the third phase being connected to a copper plate below the conducting hearth of magnesite. This furnace was first noted in METALLURGICAL AND CHEMICAL ENGINEERING, Vol. XV, page 680, December 15, 1916.

The furnace body consists of a rectangular tank made of boiler plate, strengthened by angle sections. The bottom is dished and has two steel rails rivetted to it. These rest on grooved steel rollers, and the whole furnace with its electrodes can be tilted backwards and forwards by means of a screw and gear wheels.

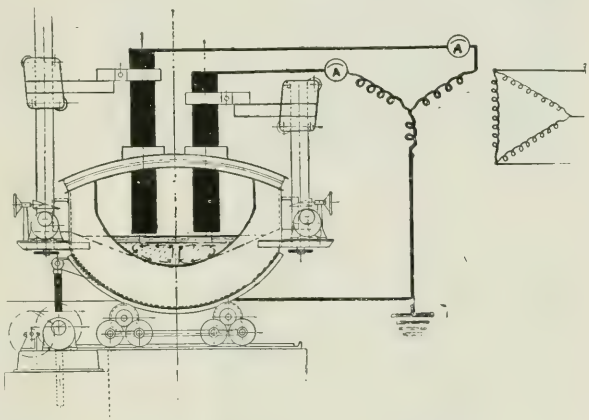

FIG. 2—SECTION OF 6-TON FURNACE

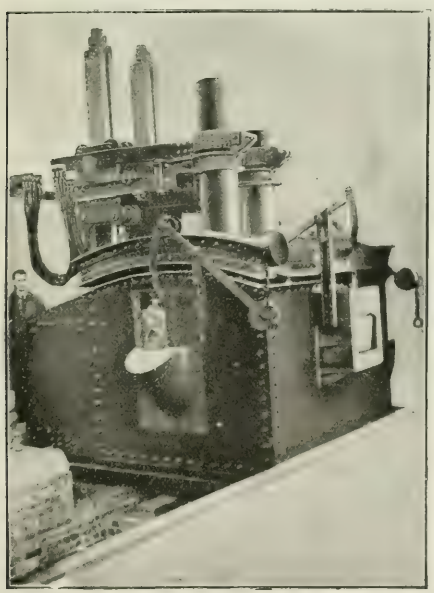

FIG. 1—VIEW OF 3-TON FURNACE

Each electrode is secured in a holder made of bronze or steel and each holder is attached to, but insulated from, a steel jib, projecting from a wheeled carriage. The carriage travels up and down a vertical mast which is made of two channel sections bolted to the side of the body. In small furnaces the electrodes are regulated by a hand wheel and in large furnaces by a motor driving through single reduction gearing.

The roof is made of silica bricks, as these are fairly good electrical insulators. They are set in a steel frame which rests on the silica brick walls, projecting above the steel body of the furnace. The roof is domed and brought as low as possible so as to reduce the wasting away of the electrode by action of the hot furnace gases. A roof will last about 100 heats and a duplicate one is provided with each furnace, so that the steel melting can be carried on except for the short time taken to change the roof.

In order to obtain an even temperature through the bath of molten metal in the electric furnace it was realized that heat must be applied below as well as above the bath, and in order to effect this the hearth of the furnace is specially constructed. About 12 per cent of the total energy of the Greaves-Etchells furnace is used in the hearth, and the "bottom heating" which results is found to be of great advantage in melting down alloys. The heavier alloys, chrome, tungsten, vanadium and nickel, sink to the bottom of the bath and if there is no bottom heating are apt to remain for a considerable time in a semi-fluid state.

The hearth lining is never less than 20 in. thick and

is constructed mainly of dolomite and magnesite in such a manner that the electrical resistance is high at the inside of the bath in proximity to the charge, and decreases rapidly to a small quantity at the outside. The current flowing through the hearth generates a considerable amount of heat immediately below the liquid in the most efficient manner possible, while the electric arcs arranged over the bath maintain the slag and surface at the desired temperature. The effect of this bottom heating is to cause convection currents in the molten metal, which insure a constant circulation, and a uniform product. The outside of the furnace bottom remains cold, comparatively little heat being lost in this direction.

At first sight the connections would appear to cause an unbalanced load on the primary supply, but the transformer ratios are arranged to give a perfect balance when the upper electrodes are in equal adjustment. The high tension electric supply is transformed by means of a delta-star system of connections to low tension, the transformer house being as near as possible to the furnace in order to avoid heavy copper costs and energy losses in the low tension connections.

The equipment has to be designed to withstand short-circuiting of the electrodes, as this occurs in all furnaces during the melting process when pieces of metal fall against the electrodes. The method usually adopted by furnace builders to provide against this is the introduction of consideration reactance in the electrical system, but unfortunately this reduces considerably the energy available in the furnace, it increases the energy losses, and also is a very objectionable load for a transmission system. The Greaves-Etchells system of transformer connections is such that the short-circuit current of one electrode must traverse two transformers in series and in different phase, which automatically lowers the power factor momentarily, and has a very strong buffer effect; the fact that there is always a permanent resistance in the path of the current through the hearth also limits very considerably the effects of short circuits. The combination of these factors provides the most effective means yet devised for protecting the supply system from surges, while allowing a high power factor to be obtained on normal load.

In all electric steel furnaces the metal is poured by tilting the furnace, and when this is effected by mounting the furnace on rockers, the end of the spout not only moves downwards but also away from the ladle. Clearly the only way to keep the spout in one position would be to rotate the furnace round it, but this is out of the question because it would mean lifting the furnace bodily and take too much power. A furnace of 10-tons capacity for example may weigh as much as 90 tons. The makers of the Greaves-Etchells furnace have compromised by arranging for the spout to descend in a vertical line so that the furnaceman and crane-man have merely to see that the ladle is lowered while the metal is running out. This is effected by the system of compensating rollers shown in Fig. 2. The furnace is carried on two sets of rollers, and as it is tilted it causes the top rollers to rotate the bottom rollers and thus move the furnace bodily forward. The wheels are so proportioned that the forward movement will keep the end of the spout moving in an approximately vertical line.

Greaves-Etchells furnaces are made in the following sizes:

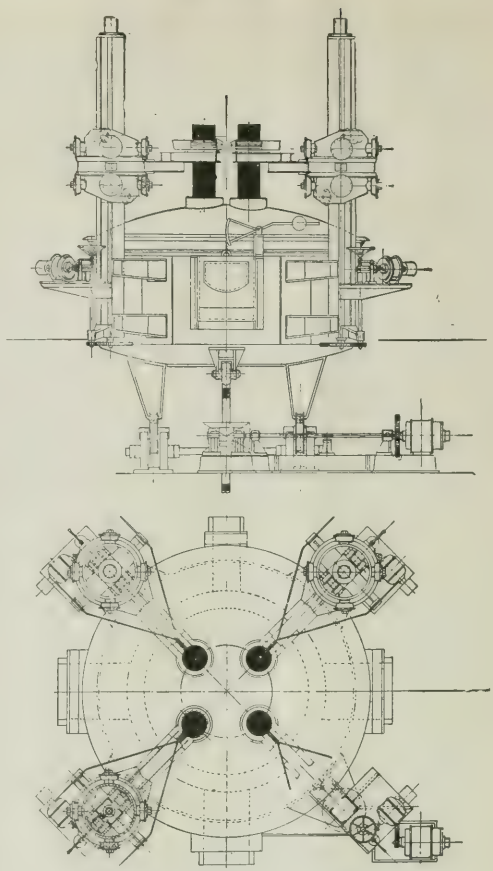

FIG. 3—PLAN AND ELEVATION OF 10-TON FURNACE

Charge	K.V.A.	Electrodes	Diameter of Graphite Electrodes
½ ton	260	2	4 in.
1½ tons	520	2	7 in.
3 tons	800	2	8 in.
6 tons	1,300	4	8 in.
9 tons	2,000	4	9 in.
12 tons	2,600	4	10 in.

For the manufacture of high speed steels or special alloy steels a ½-ton or 1½-ton furnace is usually adopted, and the furnace can finish a charge from cold material and alloys in 2 to 2½ hours, with an energy consumption of 400 units.

To make up a charge from scrap, it is usual to place steel turnings and millings on the hearth, then pieces of bar, rail and tube ends, and finally large pieces of steel. The interstices between the large pieces are filled with turnings, and some iron ore may be added. The amount of iron ore needed depends on the amount of iron oxide already present in the form of rust on the scrap. As the charge is melted, a slag of lime and fluorspar is made in order to eliminate the phosphorus. After this phosphate slag has been skimmed off, a new slag is made up of best lime, fluorspar and white sand in the proportions of 30, 10 and 5. When this has fluxed, a small quantity of finely powdered anthracite coal is spread on the slag. This charging of anthracite is

continued until the slag is deoxidized. The steel is thus finished under an atmosphere of carbonic oxide, and a slag from which the metallic oxides have been reduced. When entirely deoxidized, a sample of slag falls to a fine white powder as it cools. Deoxidation of the slag results in deoxidization of the steel, through the constant reduction of silicon from the slag, and it may be hastened by addition of small quantities of ferro-silicon.

Owing to low heat efficiency and high cost of labor crucible steel is much more expensive to manufacture than electric steel. Already several steel works have shut down their crucible plant after installing electric furnaces. The introduction of the Bessemer and open-hearth processes of making steel left crucible steel makers indifferent, owing to the fact that those methods were employed for making ordinary kinds of steel in great quantity for structures, rails, etc. The coming of the electric furnace is a different proposition, as it competes directly and successfully in the special field that the crucible steel process has held so long. In conclusion it may be mentioned that very soon there will be over fifty electric furnaces at work in the Sheffield district and the output of steel from them will be at the rate of over 200,000 tons per annum.

London, England.

Flash Annealing Large Projectiles

By Edward A. Pilnacek

In the manufacture of large projectiles, the rough shell is brought to a temperature of 1650 deg. Fahr. and then water quenched. This leaves the metal, especially the outer skin, glass hard. To allow machining, this outer skin must be softened without affecting the hardness of the inner metal. In order to obtain this effect, the shell surface must be heated to about 900 deg. Fahr. with sufficient rapidity to preclude the possibility of the inner sections of the metal having time to absorb enough heat to materially affect their hardness. This softening of a thin skin of metal is called flash-annealing.

The accomplishment of the effect explained above has been a rather difficult task. In one of our large steel mills quite a variety of types of oil and electric furnaces were tried out, the results, however, proving unsatisfactory. The shells would come through with hard spots and could only be machined with great difficulty. Two Surface Combustion gas-fired flash-annealers were finally installed and satisfactory results obtained.

The above mentioned furnaces are run on a low pressure system, air being delivered from a positive pressure blower. The quality and quantity of the mixture are controlled by a one-valve, low-pressure control. The heavy firebrick walls of the furnace,

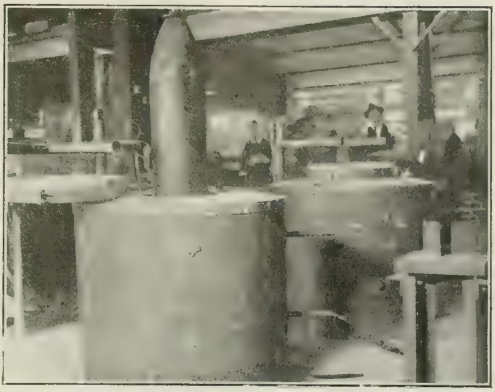

FIG. 1—FLASH ANNEALING FURNACES IN OPERATION

backed up by ample insulation, are encased in a heavy sheet metal casing, mounted on a cast iron base. The base rests on a foundation set in a shallow pit of a depth to bring the top to a convenient working height. The covers are of the usual swing type.

Fig. 1 shows the two units in operation.

Later, due to the manufacture of a larger shell, it was necessary to procure two additional flash-annealers.

Fig. 2 illustrates the latter type of furnace.

The burners are placed radially, and their nozzles are made,

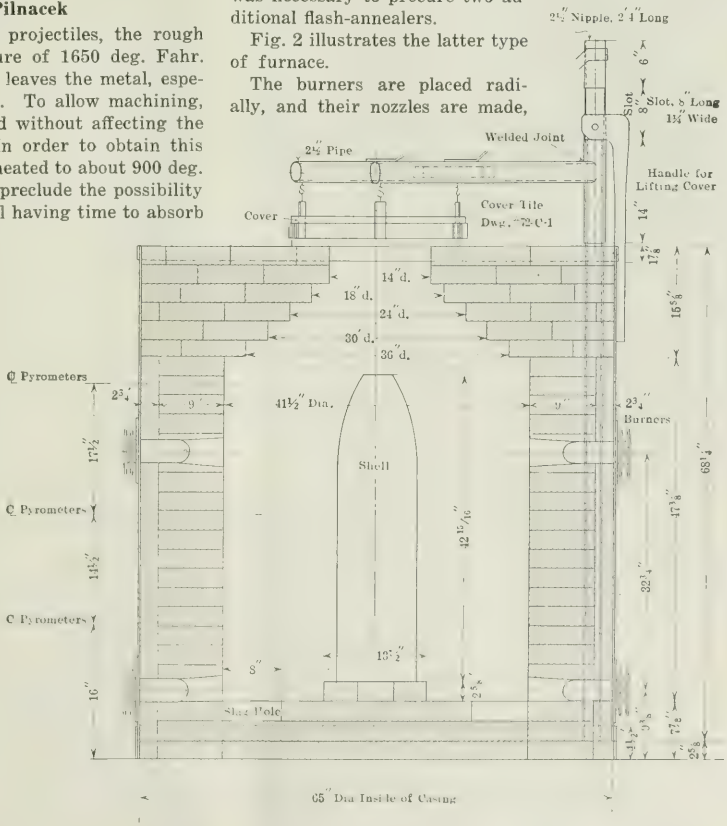

FIG. 2—FURNACE FOR ANNEALING 330-LB. SHELLS

so as to shoot the mixture tangentially upon the inner furnace walls. This causes a revolving sheet of mixture, thus giving rise to a scrubbing action of the hot gases, insuring as nearly a uniform temperature as possible at all points on the surface of the furnace. When the furnace is cold, the tunnels at the end of the burners allow complete combustion of the mixture to take place by retarding its velocity before the cold furnace walls are reached. These furnaces are of a later design using heavy firebrick walls and insulation as in the former furnaces, but run on a high pressure gas system.

The quality and quantity of the mixture are controlled by a single pipe, one-valve, high-pressure control. Gas at 2 in. of water pressure is raised to 10 lb. gage pressure by means of a booster. This high pressure gas draws in the necessary amount of atmospheric air by means of an inspirator, thus eliminating any air pipes and making a very compact furnace.

In this second installation it was deemed advisable to set the furnaces at floor level and build a platform around to enable the men to operate from a convenient working level.

The operation follows: It takes one and a half hours to bring furnace from room temperature and soak it at 1650 deg. Fahr., using 720 cu. ft. of 600 B.t.u. gas per hour. This time can be cut down if desired. When furnace has come to temperature the door is swung open and a shell lowered into it by means of an overhead crane. The shells remain in furnace anywhere from seven to fourteen minutes, the average taking ten minutes. During this time a gas rate of 540 cu. ft. per hour is maintained and at the end, the furnace temperature drops to about 1420 deg. Fahr., while the shell surface is brought to about 900 deg. Fahr. After shell has been removed and the door closed the gas rate is raised to 720 cu. ft. per hour, bringing the furnace back to 1620 deg. Fahr. in five minutes.

In this manner two furnace units turn out seven shells, weighing 330 lb. each, per hour. A few minutes are lost in handling the shells during which time furnace temperature is held with 480 cu. ft. per hour with the door open. The gas consumed per hour by the two units sums up to 1170 cu. ft., giving 168 cu. ft. gas used per shell.

Book Reviews

A Laboratory Manual of General Chemistry, with Exercises in the Preparation of Inorganic Substances. By **Arthur B. Lamb.** VI and 166 pp. Interleaved with 130 pages for notes. Cambridge, Harvard University Press, 1916.

Reviewed by Henry Max Goettsch,
Asso. Prof. of Chemistry, Univ. of Cincinnati.

In justification of adding another laboratory manual to the already existing long list of similar works, Professor Lamb has written an interesting preface, from which the following may be quoted:

"This laboratory manual has been written to meet the requirements of students of chemistry *who already possess an elementary knowledge of the subject.* (Italics are mine.) . . . How best to continue the chemical education of such students is one of the most difficult problems which confronts teachers of chemistry in our colleges and universities. . . . A time honored practice has been to ignore secondary school preparation entirely and give identical instruction to these men and to real beginners indiscriminately. *This was doubtless justifiable some years ago . . . but to-day it can only be defended on the ground of necessity.* The larger institutions recognize this and either have arranged separate laboratory sections for the differently prepared students, or, better still, give them wholly separate instruction. . . .

"The requirements then to be met by a laboratory manual of this kind are by no means easy. The most essential are, first, that those important facts and principles which the student has already studied shall be reviewed in a way sufficiently novel not to bore him, nor to encourage him to overconfidence; second, that the student's chemical horizon shall be widened by the study of new and unfamiliar substances; and third, that further important generalizations upon which the superstructure of the science is based, shall be disclosed and made clear."

With these requirements the reviewer is in substantial agreement. Turning to the contents of the manual we find them arranged in the form of fifty numbered experiments in general chemistry, constituting Part I, and of seventeen exercises in the preparation of inorganic substances, constituting Part II.

To all teachers who are fortunate in having to deal with students "who already possess an elementary knowledge of the subject," and in the opinion of the reviewer a *good* elementary knowledge should be a prerequisite, this book will make a strong appeal. It possesses many points of decided merit. There are a number of well-chosen quantitative experiments, *e.g.*, the composition of cuprous oxide, cuprous sulphide, and sulphur dioxide. An unusually large number of interesting experiments emphasize the modern aspects of the subject as brought about by the development of physical chemistry, as *e.g.*, the velocity of chemical reaction, chemical and ionic equilibrium, colloidal solution, etc. In this respect the book is to be classified as ultra modern. Three experiments are devoted to organic chemistry. This small number would seem of doubtful utility, and might profitably be eliminated in brief courses in order to gain more time for other topics.

A sufficient amount of the usual fundamental subject matter found in works of this character is given. It is of course impossible for any book to meet completely all the individual wishes of different teachers. Thus under sulphuric acid, Exp. XXI, there is given the charring action on paper, its oxidizing action on hydrogen sulphide and charcoal, and its precipitation reactions with barium, lead, and calcium salts. This would seem a rather brief treatment of this important substance and one might imagine that these points ought to have been covered in any good elementary course, and might have been eliminated in favor of experiments illustrating the chamber and contact processes.

The author states that he has purposely avoided the insertion of tests of significance only in systematic analysis. Many will not agree with him here; general chemistry offers splendid opportunities not only for an introduction to physical chemistry, but also to analysis. In this connection the complete elimination of the blow-

pipe is to be regretted; all of the older masters were adepts in its use, and its practice constitutes a pleasure for most students on account of the ease, rapidity, accuracy, and elegance of the results achieved by its use.

But these are minor points. Pedagogically the book shows everywhere the hand of the experienced, careful teacher. The "General Instructions for Laboratory Work" should prove of great value in any course. In every exercise we find assigned readings, page references being given to the excellent text of Alexander Smith, then a "Discussion" in which fundamental principles are clearly set forth, to be verified in the succeeding experiment. Full directions are given which should permit accurate work on the part of the student. Interesting "Outside Questions" conclude each exercise. These are to be solved by outside reading or reflection.

The author is fortunate in possessing a clear and direct exposition enabling him to put difficult topics in a simple and comprehensive fashion. He has given us an excellent book. The chief criticism to be levied against it, in the opinion of the reviewer, is that it is ahead of its time. Many institutions at the present time unfortunately will not have students adequately prepared to undertake its study.

The Iron Ores of Lake Superior. By **Benedict Crowell** and **C. B. Murray.** Third edition. The Penton Press Company, Cleveland, Ohio.

This book is compiled from various sources, and contains much statistical matter of interest to the miners and users of Lake Superior ore. The bulk of the book is occupied by notes on the individual mines of all the Lake Ranges. The following data is given for each mine: location, date of opening, character of ore, mining methods, depth, method of shipment, name of operator, manager and sales agent, yearly tonnage shipped since opening, and average cargo analyses of dried ore and the ore in its natural state. Good maps of each range show in color the location and extent of the ore deposits.

Introducing this portion of the book are elementary chapters on the history, geology, mineralogy, and mining methods. Then follows detailed information as to present and past freight rates, total ore shipments, dock equipment, and ore-loading records. Standard methods for sampling, analyzing and valuation of the ore are given, and an interesting chapter on beneficiation of ores also appears.

The book contains an enormous amount of information concerning the operations of this most important region, and it would be most useful to those having business relations with producing companies.

Commercial Sampling and Analysis of Coal, Coke and By-products. Methods in use by the United States Steel Corporation. The Chemists' Committee, **J. M. Camp,** Chairman.

The personnel of the sub-committee which prepared this most excellent pamphlet is sufficient guarantee of its qualities, consisting of such men as J. R. Campbell, of the H. C. Frick Coke Company; I. A. Nicholas and C. N. Norris of the Carnegie Steel Company; J. R. Harris of the Tennessee Coal, Iron & Railway Company; William Brady, J. V. Freeman and H. H. Jones of the Illinois Steel Co. It will be of extreme interest to all technical men interested in the analysis and purchase of coal and its products, and should eventually be as well known in the laboratory as is the American Bridge Company Standards in the drawing room.

As indicated in the preface, the committee has acted as a free lance in the by-product field, selecting those methods that seemed to give the most consistent results and harmonize best with plant practice, regardless of where they were to be found. No claim is made for permanency, as this field is marching so rapidly that it is impossible to formulate lasting methods save in the fundamentals.

A special feature is the progressive dry distillation method for determining the relative yields of coke and by-products from bituminous coal which should commend itself to various by-product plants, laboratories, and engineers. Although the results obtained are somewhat relative, frequent comparison of laboratory results with those obtained in actual practice will establish the proper correlation.

The Journal of the Institute of Metals. Vol. XVII ("Metal Melting" Number). Edited by **G. Shaw Scott,** M. Sc. (The Institute of Metals, 36 Victoria Street, London, S. W. 1., 21/s. net.)

Though the latest issue of "The Journal of the Institute of Metals" would be noteworthy if only on account of its containing five communications of exceptional importance bearing on as many different phases of metallurgical work, what distinguishes it from any previous volume published by the Institute, or elsewhere, is the fact that it brings to a focus the very latest ideas, information and criticism with regard to the subject of the melting of the non-ferrous metals—obviously a question of extreme moment in these days of munition-making and fuel economy. In spite of the war, which renders the continued regular publication of such scientific literature as this a matter of some difficulty, the "Journal's" amount and quality of contents are quite up to pre-war standards.

Personal

Dr. **Victor C. Alderson,** consulting engineer of Boston, has been tendered the presidency of the Colorado School of Mines at Golden, Colo. Dr. Alderson served as president of the school for ten years, retiring three years ago to devote his entire time to professional engagements.

Mr. **L. W. Bahney** has left the Sheffield Scientific School, Yale University, to accept a position as metallurgical engineer with the Scovill Manufacturing Company, Waterbury, Conn.

Mr. **De Courcy Browne,** metallurgical engineer, Goldschmidt Thermit Company, 120 Broadway, has been commissioned a second lieutenant in the ordnance department of the U. S. Army, and is connected with the second training company, Coast Artillery Corps, Fortress Monroe, Va.

Dr. **Hardee Chambliss,** chemical director of the Commercial Acid Company of St. Louis, has been commissioned major in the ordnance section of the Officers' Reserve Corps.

Mr. **Bancroft Gore** of Butte, Mont., has taken the position of metallurgical engineer of the Societe des Mines de Cuivre de Naltagua, at El Monte, Province of Santiago, Chile.

Mr. **J. H. Jowett,** formerly general sales manager, was elected vice-president of the Ingersoll-Rand Company, and Mr. L. D. Albin, formerly assistant general sales manager, was appointed general sales manager, at a meeting of the Board of Directors of the company.

Mr. Jowett and Mr. Albin will continue to make the company's New York office, at 11 Broadway, their headquarters.

Mr. **Dyke V. Keedy** has been in the three Guianas in South America since last January. He expects to arrive in New York City about Sept. 1. He reports having had a most interesting trip.

Prof. **Lionel S. Marks,** professor of mechanical engineering at Harvard and Massachusetts Institute of Technology, has been assigned by the national advisory committee on aeronautics to take charge of investigations relating to airplane-engine design now being made at the Bureau of Standards.

Mr. **C. E. McQuigg** has been given leave of absence from the position of associate professor of metallurgy at the Pennsylvania State College and is stationed at the Winchester Repeating Arms Company, New Haven, Conn., as Captain in the Ordnance Department of Officers' Reserve Corps in charge of material inspection and heat treatment.

Mr. **H. A. Richmond** has been elected managing director and treasurer of the General Abrasive Company of Niagara Falls, N. Y., and has relinquished his connection with the American Emery Wheel Works, of Providence, of which he has been president and technical expert for the past twenty years.

Mr. **F. L. Webster,** formerly manager of the San Francisco district office of the Allis-Chalmers Co., has been appointed manager of the Chicago district office, succeeding Mr. **F. von Schlegell,** resigned.

Obituary

Oscar Edmund Cary, prominent in the mining and metallurgical world has passed away. Mr. Cary, while not a mining or a metallurgical engineer by profession was connected with mining and metallurgy for many years in a business way.

Mr. Cary was born on Aug. 11, 1864, at Fort Wayne, Ind. After completing a high school course his first business activities took him to Chicago where he was connected with the Fuller & Fuller Drug Company. From here he went to Omaha, Neb., as representative for the T. W. Harvey Lumber Company. In 1893 he came West and started one of the large fruit ranches of the time near Provo, Utah. After eight years he entered the services of the American Smelting & Refining Company with which firm he remained until 1905. From then on he was connected with the Ohio & Colorado Smelting & Refining Company at Denver, Colo. This was to be his last field of action. He was assistant general manager and much beloved by the members of the firm. His death came on Monday evening, Aug. 20, 1917, at his home, 1515 East Eighth Avenue, Denver, Colo., and was due to heart failure.

Mr. Cary is survived by his mother, Mrs. Rebecca Cary, his brother W. H. Cary, who is also connected with the Ohio & Colorado Smelting & Refining Company; by a second brother H. E. Cary at Chicago and by an only son Webster Cary, superintendent of the Consolidated Copper Mines Company, of Kimberly, Nev. He was very prominent in Denver circles, having been a member of the Rotary Club, the Country Club and the Civic Association. His death is lamented by all his friends and in fact by all ever having had any connections with him.

Adolf Ritter von Baeyer, professor of chemistry at the University of München and one of Germany's best-known organic chemists, passed away during the latter part of August in Germany. He was best known for his work in coal tar chemistry, especially synthetic indigo and eosin. He was a professor at the University of Berlin in 1866, at Strässberg in 1872, going to München in 1875, where he built a large new laboratory. He did considerable work in the laboratory of Graebe and Liebermann in 1868. In 1905 he was the recipient of the Nobel prize.

CURRENT MARKET REPORTS

Non-Ferrous Metal Market

Saturday, Aug. 25.—The metal markets remain intrenched in their stagnant position. Prices are practically unchanged on the important items, such as copper, lead, tin and spelter.

Copper.—The copper trade has been awaiting the price agreement between the producers and the Government. What few sales have been made have been consummated at prices averaging 29.00 cents for Lake and 27.00 cents for electrolytic, which are the prices quoted at the present time.

Tin.—Tin remains at 62⅛ to 62½ cents for Straits, with no new developments. Other grades of tin, such as Banca and Chinese, are offered at several cents under Straits as usual.

Lead.—The only thing of interest in the lead market is a slight disposition on the part of independents to shade their prices. They are asking 10½ to 10⅞ cents, with the Trust price remaining at 11.00 cents.

Spelter.—Dullness continues with prompt spelter nominally quoted a trifle lower at 8⅛ cents.

Other Metals	
Antimony, Chinese and Japanese, pound	$0.15
Aluminium, No. 1 Virgin, 98-99 per cent, pound	.48
Magnesium, metallic, pound	2.00–2.50
Nickel, electrolytic, pound	.55
Cobalt, pound	2.70
Cadmium, pound	1.50
Quicksilver, flask	115.00
Silver, ounce	.88¼
Platinum, pure, ounce	105.00
Palladium, ounce	115.00

The Iron and Steel Market

The iron and steel market continues in a stagnant condition. In other words, it continues to make progress towards a general readjustment on a lower scale of market values. The situation is the familiar one that always develops after a period of heavy buying with rapidly advancing prices. The final resolution sees quick action, but the preparatory period is just as essential, the mutual obligations of buyers and sellers being in process of fulfillment preparatory to the making of a fresh start.

The unique feature of the present readjustment is that the Government is involved and the extent of its connection is not known. The Government now exercises certain influences and may exercise more. It has power to fix prices on the steel it buys for prosecuting

the war, prices much lower, of course, than those quoted for some time past as representing the market, and these prices are largely unfixed as yet. When fixed they will exert an influence upon the minds of buyers, encouraging them to expect lower prices also. The Government exerts also a sentimental influence upon buyers, by the "one price for all" doctrine enunciated by President Wilson on July 12, a doctrine which the recently created War Industries Board, for purchasing supplies, has reiterated. The inference in the minds of many is that if iron and steel prices do not recede satisfactorily the Administration will seek power through legislative action to bring them down.

In another manner, both direct and sentimental, the Government can, or rather will, exercise an influence upon iron and steel prices, and that arises from the power given the President by the Food Control Law to fix prices for coal and coke. When on Aug. 21 the Administration announced coal prices at an average level of $2 per net ton at mine for mine-run it set a lower figure than had been expected, and the impression was naturally given that it would seek the establishment of lower iron and steel prices than had been expected. That influence helping the market towards its readjustment is sentimental, as in the aggregate the cost of producing steel is not greatly reduced. A direct influence will be exerted when a lower price for coke is forced, as the cost of making pig iron will be materially reduced, and buyers of pig iron will be further confirmed in their policy of staying out of the market until prices are lower.

Transactions in pig iron are practically nil, business being confined to very small lots for early shipment, with occasional resales of somewhat larger lots. Through such reselling Bessemer has scored a decline of $2 a ton, to not over $53, valley, the offerings being of iron that had been bought for export but could not be moved.

In unfinished steel there has been more action, but as to quotations rather than actual turnover of tonnage. The advance in billets was completed early in June, the established level then being $95 to $100. For a few weeks this represented an actual market, the quotation later becoming nominal, awaiting a reduction through actual offerings at lower prices. These began just before the middle of August, and before the end of the month there were offerings down to $75 which found only an occasional taker, so that, apparently, the $20 decline was only the beginning. Sheet bars, which had attained a level of $105 to $110, were offered down to $85 if not lower.

The decline in the scrap market, which began late in June, continued until the past fortnight, in which period there has been some tendency to reaction towards a slightly firmer condition.

In finished steel products the stagnation which began about July 1 has continued, and has, if possible, been accentuated in the past week or two. Domestic buyers have shown wonderful powers for staying out of the market, as even their purchases for early deliveries are relatively small. The case of export demand is different, there being heavy demand for various products, including plates and sheets in particular, and even higher prices than formerly are bid for sheets.

There has, however, been no definte decline in finished steel products, which are, with the possible exception of plates, quoted at as high prices as formerly. The export embargo on scrap, pig iron, billets, etc., plates and structural material, which became a tight one Aug. 15, when the Government ceased to grant permits except when it could be shown that the material to be exported would be used strictly for prosecuting the war, has had some influence upon the plate market, as deliveries of large tonnages have been held up, and the mills do not know whether to continue rolling upon their orders in expectation of permits being granted later, or to offer to sell their capacity over again in the open market. There have been occasional offerings of plates in consequence at lower prices, down to 8c.

Production increased somewhat the latter part of August on account of a moderation in the weather. Production of steel ingots in the first half of the year was at the rate of about 43,000,000 tons, against actual production of 41,400,000 tons in 1916, while July showed an average rate of 44,000,000 tons and August will make a still better showing. The gain in production over 1916 is decidedly less than the increase in capacity.

Mills are steadily reducing the volume of their obligations on books, but it will be several months, in most instances, before they stand in need of additional orders. While the average shipping value is constantly increasing through the working off of older and lower-priced orders, the average invoice price at this time is but little more than half the present quotable market, which is one that was developed on relatively prompt deliveries after the buying for regular forward deliveries had dropped to small proportions.

Chemical Market

Benzol.—The ultimate attitudes of the allied governments regarding the purchases of picric acid are still an unknown equation, and the movement in benzol has been slow. Domestic consumers are playing a waiting game and following the issues carefully; in the meantime supplies appear to be accumulating somewhat, and there is a noticeable effort on the part of some producers to dispose of their surplus holdings, with the attendant result that the market is not particularly strong.

Nitrobenzol.—A routine movement of stocks is going on, but demand is far from active. Prices, however, are remaining moderately steady. *Dinitrobenzol.*—Production of this intermediate is not large enough to allow of much surplus, although there is not an unusually heavy demand. Prices have not been given to marked revision, and sellers' ideas are unchanged. *Dinitro Chlorbenzol.*—With a somewhat greater production, stocks are more or less plentiful, and within the last few weeks competition has induced somewhat lower figures. *Monochlor Benzol.*—One or two moderately good export orders have recently been placed, and a fair domestic demand has been in evidence. The fact, however, that production has increased has kept the market at comparatively low levels, and there is no expectation of an immediate advance in values.

Toluol.—Because of the fact that a very large percentage of production is going directly into consumption on Government contracts, and for dye manufacturing enterprises, a comparatively small amount is reaching the open market. Prices are firm and the tendency is toward continued firmness. This attitude is reflected in the fact that some large producers are not taking a pound of outside contract business and others quote prices at least equal to the spot market. *Ortho-*

Toluidine.—Ortho production is still confined to comparatively few sources, a fact which keeps supplies limited, and barely able to cope with the steady demand that is in evidence. Prices show considerable firmness. This condition is even more true of the *Para*, of which a smaller yield is returned; demand is heavier, and some makers are not in a position to take business for immediate delivery. Prices have advanced and are now firmly maintained at $2.00 to $2.25. *Ortho Nitro Toluol* and *Para Nitro Toluol* have been in fairly urgent request and under light supply the market is holding with no little firmness.

Xylol.—While demand has broadened somewhat the increased production has been instrumental in bringing about a situation that not altogether makes for optimism on the part of producers. Supplies in some directions have accumulated and the pure grade is offered at times at lower prices. This is also partly true of the commercial.

Phenol.—The undertone is considerably stronger, and there appears to be a slight upward movement. Recent large purchases took much of the surplus from the market, and leading sellers who have not sold up for nearby delivery have advanced their prices from one to two cents.

Dinitro Phenol.—With domestic production somewhat in excess of immediate demand, there has come about a much easier tone to the market, reflected in present prices which are from 5c. to 8c. below the figures quoted two weeks ago.

Naphthaline Flakes.—Some moderately important business has been passing during the fortnight although as production goes along steadily, supply is at least equal to demand, and prices have been shaded somewhat for nearby delivery and contracts.

Heavy Chemicals.—The sharp upward movement in soda ash during last week was not particularly surprising, in view of the fact that producers for the most part had been in a well sold up condition for some time. Neither, however, was the reaction which set in the latter part of last week and which continues now, of a very surprising nature; for while the firmness is justified, the advance was brought about to a great extent to speculative holders who control a large share of available supplies. *Caustic Soda.*—The continued strength and steady advance of this material has been more or less phenomenal. Trading for nearby delivery, and on all forward positions is only restricted by the meagerness of offerings. While it is true that speculative interests have played a more or less important part, the consuming demands and export requirements have been the big factors in producing the tight situation that now prevails.

Bleaching Powder.—While this article has been dull all summer, and prices have been unusually low, there is now a somewhat firmer tone to the market, induced by the widening of inquiry both for domestic use and in export packages. The fact that makers are confident that the market will regain its lost strength is evidenced by the higher quotations made for future deliveries than for spot business.

Chlorate of Potash.—The market is moderately firm and there is a tendency noted in some directions toward higher prices. The absence of important demand, however, keeps the market from advancing. The Japanese product is offered here from some quarters at moderately lower figures, and some business is reported. *Chlorate of Soda* is coming in for a fair inquiry, but nothing unusual has developed. *Bichromate of Potash.*—The market is more active, and supplies in second hands have diminished to the point where offerings are nominal. Manufacturers have advanced their price and as the time for taking contract business for 1918 is near at hand, the prospects are that the market will remain strong for some time. *Prussiates of Potash* are in big demand, and supplies are scarce. There is a noteworthy strength to the market on yellow prussiate in particular, and the Japanese product which has met with considerable favor here is only offered for future shipment from the Orient.

Copper Sulphate.—The market is not particularly active, and the demand is being taken care of with little trouble. One producer has lowered the price fractionally, but as a rule the market keeps steady.

Arsenic.—Offerings vary in price according to seller. There is a fair activity, but future positions are quoted at somewhat lower prices than for spot delivery and slight concessions are being made for nearby delivery as well.

The market for acids is, as a general rule, in a healthy condition; this is especially true of the mineral acids, the demand for which is wide.

Muriatic Acid.—Recent government purchases have established a firm tone for all grades, and producers in some cases have no supplies to sell at this time either for nearby delivery or futures. *Nitric Acid.*—On account of the high price of nitrate of soda, the market for this acid has increased considerably and prices are held strongly at the recently increased levels.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET AUGUST 23, 1917

Acetic anhydride	lb.	1.90 —	2.00
Acetone, drums	lb.	.27 —	.27½
Acid, acetic, 28 per cent	lb.	.05½ —	.06

INDUSTRIAL

Financial, Construction and Manufacturers' News

Financial

New Companies

The American & Foreign Paper Corp. To manufacture paper and paper products. Incorporators are J. H. Bardsley, A. Isaacson, B. H. Rohrey, 259 Broadway.

American Electrothermic Smelting Corp., Manhattan. $100,000. General mining business. M. F. Connor, Jr., F. A. Collins, J. L. Covey, 568 West 149th Street.

Belleville Metal & Chemical Co., 241 Cortlandt Street, Belleville, N. J. $50,000. To manufacture chemicals.

The Big Lake Oil & Gas Company. $100,000. Incorporators are Burton E. Green, M. H. Whittier, William G. Kerckhoff, H. L. Westbrook and F. B. Sutton.

Bruner Chemical Company, Perth Amboy, N. J., manufacture chemicals; capital, $10,000. Incorporators: Willard L. Bruner, Perth Amboy; Leidy S. Bruner, Lansdale, Pa.; J. Norman Bruner, Philadelphia.

The Chemical Alliance of New Haven. Incorporators are James F. McClelland, Walter S. Ferris and Harrison T. Shelton.

Chillicothe Cotton Oil Company, Chillicothe, Tex., $125,000. Incorporators are C. E. Carter, W. L. Campbell, Jr., and Richard T. Harris.

F. A. Dillingham, Inc., N. Y. City; drugs and chemicals; 100 shares preferred stock $100 each, 4000 shares common stock no par value, active capital $30,000. Incorporators: A. B. Champlin, F. A. Dillingham and R. P. Ballard, 17 West Forty-second Street.

The Fairfield Pure Water Corp., $225,000. To manufacture, design, etc., filtration and distillation plants, manufacture alkalies, chemicals, smeltings, etc., of metal. Incorporators are L. H. Moore, Broadway and Seventy-second Street, New York City, N. Y. V. R. Neil, 26 Dock Street, Yonkers, and M. Rogers, 426 Twelfth Street, West New York, N. J.

The Fort Smith Glass Products Company, Little Rock, Ark., $46,000. To manufacture high grade glass products. Incorporators are Charles Becker, president; George L. K. Hammons; vice-president, C. A. Frederich; secretary-treasurer, Herman Schuchnact, Robert Malcom, and E. D. Holmes. All are residents of Chicago except Mr. Frederich, who lives in Little Rock.

Hamburg Foundry Company, Hamburg, Pa., $50,000. Incorporator, D. H. Redmond, Philadelphia.

The Imperial Machine & Foundry Corp., Manhattan. $300,000. To manufacture metals, mill supplies and machinery. Incorporators are H. Robinson, 108 West Thirty-fourth Street; J. G. Abramson, R. A. Abramson, 30 Church Street, New York City.

The Kaolin Refining Company, Spokane, $100,000. Happy & Happy.

Lincoln Chemical Works, Lincoln, N. J., manufacture chemicals. Capital, $10,000. Incorporators: Nat S. Kallmann, Long Branch; Hyman Beler, Morris Katz, Brooklyn.

McKeesport Enameling Co., McKeesport, Pa. To manufacture paints, enamels and varnishes. Capital, $50,000. Incorporators: James W. Nesbit, A. Clifford Wiltshire and J. R. Worley, McKeesport, Pa.

M. B. Manufacturing Corp., Manhattan, $5,500. To manufacture and deal in chemicals. Incorporators are N. Lazarus, A. Phillipe, A. Romeo 5000 Broadway.

Mackay System, Inc., New York, $12,500. To manufacture chemicals, dyes, paints, and carry on general paint business, 2500 shares common stock, no par value. Incorporators are H. A. St. George, E. A. Darr, V. H. Vreeland, 41 Park Row.

Marvelo Detergent Company, Chicago. $1,000,000.

The Mathieson Alkali Works, Inc., Virginia, $2,000,000. To manufacture salt, soda, bleaching powder, and chemicals. Representative, F. B. Richards, Buffalo.

The Merchants Steel & Supply Company of Chicago. $50,000.

The National Concrete Products Company, $50,000. Incorporators are E. B. Blinn, Henry Barkschat, E. J. Pyle, William C. Crowell and Leo D. MacLaughlin.

National Rolling Company, Vincennes, Ind. $300,000.

Natural Dye Woods, Ltd., N. Y. City; importing and exporting and general realty agents; capital, $10,000. Incorporators, F. W. Will, G. H. Boyce and T. H. Phillips, Jr., Essex Street, Brooklyn.

Neptune Chemical Corporation, Brooklyn, $5,000. Incorporators are Herman Finkelstein, Katie Finkelstein, Edward L. Petow.

Nitrogen Fixation Corporation, Manhattan. $1,000,000. Chemical manufacturing. Incorporators, Josef F. A. Comstdet, J. Robert Rubin, Sidney M. Weil.

Ontario Smelting Company, Wilmington, Del., $250,000. Incorporators are M. L. Gatchell, L. A. Irwin, Harry W. Davis.

The Pacific Potato Starch Company, Portland, Ore., has been organized, with capital stock of $65,000, to manufacture by-products from potato culls. Machinery will be installed immediately in a new plant to be built here. Company is formed by L. W. Cronan of Portland, and J. E. Cronan and associates of Ione, Ore.

The Perkiomen Paper Mills Co., of Pennsburg. Incorporators are Chas. Q. Hillegass and L. S. Jacoby.

Peru Foundry Company, Peru, Ind., $60,000. General foundry business. Incorporators are M. F. Gartland, J. H. Schaumleffel, P. V. Gartland, Frank X. Gartland, John C. Haswell, John P. Whalen, Harry J Schaumleffel.

The Petroleum Products Company, Franklin, capital $50,000. Incorporators are John F. La Rue, J. Nall La Rue and J. C. Parson.

The St. Lawrence Metal Products Corp., $200,000. To manufacture metal wood and chemical products. Incorporators are E. J. Furley, Montreal, Canada, P. N. Fitzgibbons, 102 Washington Street, Ogdensburg, and J. E. Fell, 44 New York Avenue, New York City, N. Y.

The Silver Hill Mining Company, Spokane, Wash., has been incorporated for $150,000 by B. W. Dunn, C. J. McDonald and C. W. Greenough.

U. S. P. Salicylic Co., Inc., Manhattan. $50,000. To manufacture acids, chemicals, etc. Incorporators are V. E. Gartz, 60 Wall Street; A. Golden, Times Building, E. W. Kluchansky, New York.

Uintah Basin Producing and Refining Company, $3,000,000. To drill and operate for petroleum, oil and gas. Incorporators are F. D. Wise, C. A. Campbell, J. P. Koehler, Indianapolis, Ind.

The Valley Steel Co., organized several months ago under the laws of New York to build and operate a $1,000,000 steel mill in Milwaukee, which now is under construction at St. Francis, near Milwaukee, has been reincorporated under the laws of Delaware, with the new name of General Steel Co. The new corporation has 13,000 shares of preferred stock, each with a par value of $50, and 16,000 shares of common stock with no par value.

The West Kentucky Zinc & Smelting Co., Crittenden County, Ky. $2,500. To operate a zinc mine. Incorporators are B. D. Hill, Lee Oldham, F. M. Brown and J. W. Downer.

West Rutherford Color and Chemical Company, Inc., Manhattan. $7,500. To manufacture chemicals, colors and dyes. Incorporators are Frederick J. Saccomani, Joseph Brietenstein and Agnes Dolan.

J. F. White & Co., Inc., New York. $1,000,000. To manufacture jute, flax, cotton, hemp, wood pulp, paper goods and dry goods. Incorporators are H. D. Cooper, H. A. Murphy, W. S. Kimball, 54 Worth Street.

Construction and Operation

Arizona

DOUGLAS.—Attorney D. A. Richardson of Douglas has announced that he has organized a company to build two tanning plants, one for Douglas and the other for Agua Prieta. They will cost $10,000 each. W. C. Humphrey, a well known mining man, is associated with him in the enterprise.

TUCSON.—A carbonate leaching plant, similar to that at Ajo, is planned for the Twin Buttes section, south of this city. The Magnate Copper Company has twenty-nine claims on which the surface ores are believed susceptible to leaching.

Hughes & Dier of Philadelphia, who are backing the enterprise, are understood to have indicated that $5,000,000 will be available for construction of suitable works in the event a favorable report is given by Walter Harvey Weed, who has been placed in general charge. Development of the company's property has been commenced with churn drills on a sixty-acre tract, in which concentrating ore already has been developed. Some richer ore now is being shipped to El Paso.

A matting furnace is planned by the Duquesne Mining & Reduction Company to further reduce concentrates now being shipped.

At Cananea the Carnegie Lead & Zinc Company is preparing to spend $400,000 on a new mill and provision of railroad service. The concentrator will have capacity for 500 tons of ore a day, and will be equipped with flotation, to better the present extraction of only 80 per cent. J. H. Sanford, Jr., is in charge of the mine. R. P. Burgan was elected president at the last meeting.

TUCSON.—Announcement that New Cornelia will erect a 5000-ton flotation plant and a 2000-ton smelter at Ajo as the result of the purchase of the Ajo Consolidated property was made in Tucson recently by Captain John C. Greenway, general manager of Calumet & Arizona and New Cornelia.

The big flotation plant will be ready for operation in two years. It will produce 750 tons of concentrates daily, which will be sent to the smelter.

California

SAN FRANCISCO.—A San Francisco firm has been awarded the contract for the construction of the new unit of the California-Hawaiian Sugar refinery at Crockett. The exact price was not given, but it is estimated that the job will cost about $2,500,000. Work will be started at once and at the same time the reclamation of the tidelands in the vicinity of the refinery will be begun. When the reclamation work is finished it will be possible for the company to place the large warehouses and wharves so that ships may tie up to them and unload.

SANTA ROSA.—The rebuilding of the big Vallejo plant of the Santa Rosa-Vallejo Tanning Company, which was recently destroyed by fire, is to be undertaken at once, according to an announcement by the company's officials.

Connecticut

NEW BRITAIN.—The American Hardware Corporation having obtained authority from the Public Utilities Commission to construct a spur track through Bigelow Street, it is expected that work will be commenced soon upon a new foundry building there to replace the annex recently destroyed by fire

NEW HAVEN.—The Magnus Company, Inc., has taken out a permit from Building Inspector Austin's office for a foundry, 40-50 Eddy Street, to cost $50,000.

Florida

ST. PETERSBURG. The utilization of shark skins in producing leather will become a Florida industry, if the announcement of J. F. Lavarne of Pittsburgh of a $300,000 plant at St. Petersburg is realized. Mr. Lavarne has been experimenting on tanning shark skins and handling all kinds of fish by-products for years.

Mr. Lavarne has organized the Universal By-Products Company of Pittsburgh, Pa., of which he is president, and proposes the enlargement of a plant in Alaska, where the operations have been carried on, the building of another plant at Seattle, Wash., to cost upwards of $300,000, and another plant at St. Petersburg costing approximately the same amount. It is his expectation to start work on the St. Petersburg plant this winter, and plans are being drawn.

Idaho

KELLOGG.—The first shipment of crude lead produced by the Bunker Hill & Sullivan Mining & Concentrating Company has left the smelter destined for Pennsylvania. Its value was $10,000. Shipments will be made regularly from now on.

Illinois

CHICAGO.—The Eastern Metal Refining Company has leased land on Fiftieth Street, between Fifth and Princeton Avenues, and will erect other improvements at a cost of $20,000.

PEORIA.—A large malleable foundry, in which a large amount of Peoria capital is invested, is to be located in Averyville in the near future.

The company has purchased a strip of ground below the C. R. I. & P. tracks and between the United Box Board Company and the Avery Company grounds, and the preliminary work toward constructing a large up-to-date foundry will be started at once.

Kentucky

LOUISVILLE.—A $500,000 oil refinery that will have an immediate capacity of 2500 barrels daily is to be erected at once by the Aetna Refining Company on forty acres of ground, located on Gibson's Lane near the State fair grounds, that company officials purchased recently from Mrs. C. C. McClarty.

Oil from Kentucky fields will be handled almost exclusively in the petroleum plant. The oil will be brought in barges down the Kentucky River from the so-called Estill County district. It is announced the refinery will have an ultimate capacity of 4000 barrels daily. Fifty men will be employed as soon as the plant is opened and about 100 employees will be on the payroll when the refinery is ready to run "full force," it is said.

Louisiana

SHREVEPORT.—The Western Carbon Company, a subsidiary of the Columbian Carbon Company, is erecting a carbon plant at Cedar Grove, near here, to cost about $125,000, with capacity of 100 barrels daily, to be in operation in 60 days, using natural gas.

Maryland

BALTIMORE.—Extensive plans for the renovation of the plant of the Curtis Bay Chemical Company, at Stone House Cove, Anne Arundel County, which ceased the manufacture of acetone about Aug. 1, and which discharged more than half of its employees perparatory to closing, are being rushed to completion, and when improvements are completed it may be that more men will be employed than heretofore and that the output will be of much greater value than the former acetone output. Already, it is known on good authority, that potash has been successfully manufactured from molasses refuse obtained at the plant of the Curtis Bay Distillery, at Curtis Bay, a branch of the United States Industrial Alcohol Company of New York which has been turning out thousands of barrels of alcohol monthly. Aside from this important product, important oils, greases and animal feed are to be turned out.

Minnesota

DULUTH.—The Minnesota Steel Company will expend $2,000,000 on new construction at the Duluth plant this year, and next year will begin the construction of the second furnace unit of the plant, involving the expenditure of several millions of dollars.

Advices were received in Duluth from the New York headquarters of the United States Steel Corporation that two blast furnaces and four open hearth furnaces, costing $1,500,000, would be built as soon as plans can be completed and contracts let, completing the first unit of four blast furnaces and fourteen open hearth furnaces.

Work has been started on the erection of a benzol plant which will cost about $500,000.

MINNEAPOLIS.—The Northern Welding Company has sold its Minneapolis plant and Duluth branch, the Duluth Gas Company, to the Air Reduction Company of New York. The transaction involved $400,000.

The Minneapolis plant is at this time making welding equipment for the Government.

Montana

HELENA.—It is stated that representatives of Pennsylvania steel mills have been looking over ground in Granite County, near here, with a view of erecting a large smelter for reduction of manganese ore, and with a possibility of steel mills being erected in Montana. The manganese now being mined in Granite County is mixed with the iron from iron deposits found in other parts of the state.

BUTTE.—The Butte-Detroit Mill will be in shape early in August to handle 200 to 400 tons manganese ore daily. Changes in machinery at the "front end," where the crushers and jigs are located, are now under way. Mill will be operated as a custom plant, and will be the only mill in Butte handling manganese ores.

WINDY GAP.—The Montana Tungsten Company has struck very rich tungsten ore near this city, and will install machinery for sinking shafts and install a mill.

New Jersey

MILLVILLE.—The largest glass plants in Millville closed their blast for the summer stop July 28, and almost all of the 4000 glass workers who have been working here for the last eleven months will enjoy a five weeks' vacation. One furnace remains in operation at the T. C. Wheaton Company glass works and one at the Millville Bottle Works.

Extensive improvements will be made at all the works during the idle period, and it is reported that at least two new factories will be built and put into full operation in the early fall. The wages made by the tending boys throughout the season has exceeded by far any wages ever before paid to them in the history of the glass industry.

NEWARK.—The Orr Chemical Company has leased the one-story concrete block building and several smaller structures at 344 Thomas Street, for the manufacture of valerianic acid.

New Mexico

SANTA FE.—The 100-ton smelter that is being erected by the Sandoval Consolidated Copper Company in the Nacimiento Mountains, 60 miles west of Santa Fe, is completed and is to start operations shortly. The ore will come from twenty-eight claims formerly managed by Prof. William Jenks and which produced almost 5,000,000 lb. of copper.

New York

BUFFALO.—A steel and brick coal house, covered scrap yard and an electric furnace will be erected by the Sizer Forge Company at 238 Larkin Street at a cost of $109,500, according to building plans filed by the company.

North Carolina

GREENSBORO.—Swift & Co. has begun work on the site for the fertilizer factory just south of Greensboro. The contract for the building is in the hands of A. D. O'Brien, of Wilmington.

WASHINGTON.—The Virginia-Carolina Chemical Company in the near future will erect a fertilizer factory with an annual capacity of 40,000 tons at Washington, N. C. Owing to the increased difficulty of obtaining necessary supplies, earnings derived from fertilizer during the past year have not been as great as at first anticipated, although they have been satisfactory.

WILMINGTON.—Old North State Pulp & Paper Mills, which heretofore has manufactured only pulp from North Carolina timber, has increased its capital stock to $2,000,000 and will go extensively into the manufacture of paper. The present plans call for the immediate building of a paper mill which is to have a daily capacity of 100 tons. The company has purchased the site for the new mills, and will start work on the same at once.

Oregon

CULVER.—Word has been received here from C. F. A. Pock, who has been in New York for some time financing the gas smelter to be built between Culver and Crooked River Rim, that he has been successful and the smelter will soon be started

GOLD HILL.—O. M. Raseau of Seattle, representing iron ore interests, has inspected the iron ore deposits at Gold Hill, and has found sufficient magnesite blended with hematite-magnetite iron ore deposit to make a good ferro-manganese base. As soon as extent of deposit has been determined, shipments will be started.

OREGON CITY.—The Crown Willamette Paper Company has announced a voluntary decrease in the hours of labor at its plant from ten to nine hours, with ten hours' pay.

PORTLAND.—Ore shipments to the new blast furnace that is to be started at the Oswego, Ore., plant of the Pacific Coast Steel Company, will start early in October from the iron ranges of San Bernardino County, California. About 400 tons a week will be delivered with gradual increase until at the end of two years, it will reach 10,000 a month. Under the same contracts ore shipments will move to the company's furnace at Irondale, which will be blown in within the next few weeks.

Pennsylvania

ALLENPORT.—The Pittsburgh Steel Products Company, which has a large plant at Monessen, Pa., for the manufacture of seamless steel tubes, plans to build new works at Allenport, opposite Monessen, on the Monongahela River, where it owns about 300 acres. This plant will probably be larger than the Monessen plant. The capacity of the Monessen plant is 60,000 tons seamless steel tubes per annum.

POTTSVILLE.—The owners of the Eastern Steel Company of this city, in which New York capitalists have invested about $9,000,000 during the present year, are to make improvements, extensions and concentration at the mammoth works, which will mean an increase of more than 33 per cent in the present finished, wrought and steel billets production annually. A steel converter or melting pot is among the new machinery to be installed. The increase was found a necessity, because the present output is not sufficient to keep all the rolling departments supplied to their capacity.

READING.—The Temple Malleable Iron & Steel Company, operating a plant at Temple, has announced plans for a brick, steel and concrete foundry to cover seven acres and to cost $500,000 with equipment.

Tennessee

MEMPHIS.—While cotton is still king in the South, the peanut promises to dispute or to share its dominion in some sections as part of well-balanced farming practice. The State of Texas, for example, has planted 600,000 acres to peanuts, more than doubling the acreage of last year, according to figures just issued by the United States Department of Agriculture. The prospective crop, on the same authority, is more than 70,000,000 bushels for the whole South. Texas already had the largest acreage in 1916, though in 1909 it stood sixth, with most of the Atlantic and Gulf Coast States ahead. Georgia jumped from 190,000 acres last year to 420,000. The increase in Texas has been an index of the increase throughout the lower South, though the proportionate increase elsewhere has not been so great. For the South as a whole, however, it is remarkable that the acreage has increased from less than a million and a quarter acres to more than two million acres. Practically no peanut oil was made in this country prior to 1915, and so far the oil mill men had not been benefited; but it was brought to their attention that the United States, in 1914, was importing 1,332,108 gal. of peanut oil and 44,549,789 lb. of nuts. More than half of the oil went to Chicago and presumably went into oleomargarine and the lower grades into soap. The oil brought more than cottonseed oil. A few changes in the oil mills, having to do largely with the cleaning of the peanuts, and they were ready for the extraction, and the peanuts began to come to them. Recently there has been such a demand for the nuts themselves, for manufacture into products elsewhere, that the mills have not been doing much extraction because they could make more handling the nuts themselves than they could by selling the extracted product

Texas

HOUSTON.—A plant for the manufacture of absorbent cotton and the conversion of cotton linters into artificial silk is planned here by Frederick Wide of London, England, representing British capitalists. Mr. Wide, who is here from New York, went down the channel as the guest of Benn Garrett, president of the Pan-American Trading Company, from whom he has secured his location. He will build his plant immediately west of Industrial City, adjoining the Pan-American Company's shipyards, and will occupy 200 ft. of water frontage. He has already authorized construction of his first unit, 60 x 100 ft., and has assembled most of his machinery in Philadelphia. To expedite work he has contracted with the Pan-American Company to supply all needed brick. The company will use its own clay deposit, burned in its own kilns. Construction of the kilns began Wednesday morning. They will be built on Greens Bayou, the westernmost boundary of the Pan-American tract, and will have a capacity of 150,000 bricks. Fuel to keep the kilns going will also come off the site. Wood fuel will be used. In 90 days the Wide plant will be in operation, turning out 1000 lb. of absorbent cotton daily for Great Britain

Utah

IDAHO FALLS.—By a deal closed recently in Salt Lake by Dr. H. A. Anderson of Rigby, Idaho, the Beet Growers Sugar Company acquired title to a plant in the outskirts of the town of Rigby. Dr. Anderson, chairman of the executive committee of the company and formerly county physician of Salt Lake County, announced last night that plans for the erection of the plant would be prepared at once, the contract let, and work started on the factory within the next sixty days, with a view to having everything in readiness for handling the 1918 sugar beet crop. The general offices of the company are located at Idaho Falls, but a branch office, under the charge of Treasurer H. F. Aller, has been opened at 307 Dooly Building, Salt Lake.

Washington

ABERDEEN.—The Thomas Pulp & Paper Company of Portland has selected Aberdeen as the site of its proposed big pulp and paper plant, according to R. Thomas, president. The company has purchased 300 acres of coal land and will mine its own coal, 300 tons of which will be used daily. Thomas is inventor of a process to make paper out of fir as well as spruce.

CHEWELAH.—The Northwest Magnesite Company shipped 189 carloads of magnesite from Chewelah during July, according to report by the company. It is expected that increased shipments will be made as development proceeds, and means of transportation are increased. The company is progressing with installation of its plant which will be used to manufacture magnesite products.

LEAVENWORTH.—The Lahnigan Company of Butte, Mont., has recently purchased a square mile tract near this city, on which it is rumored a smelter is to be erected. Tremendous quantities of marble close by is expected to furnish lime.

SEATTLE.—The Eagle Brass Foundry has let contract for two-story, 90 x 105 ft. mill construction factory building, to cost $10,000.

SPOKANE. — The Muscovite Mining Company here is busy turning out "eyes" for gas masks for soldiers, to be used in France, "windows" for heating stoves, and all kinds of transparent squares, circles and rectangles. Company owns mines in Idaho, and the cutting plant in Spokane has been in operation only a few weeks. To meet the demand that has already developed the company plans to install new machinery, including a grinder, to be used in working up the scraps and waste from the blocks and sheets of mica into powder to be used in manufacture of lubricants, roofing material, wall paper, fireproof paints, etc. Dr. H. E. Elliott of Spokane is president of the company.

SPOKANE.—The Spokane Acetylene Gas Company plans to extend the scope of its activities by financing the company and constructing a big plant in Spokane. The present plant is inadequate to meet the demands of the automobile accessory houses and welding plants in the city. It is estimated that there is a demand for more than 45,000 cu. ft. of acetylene gas in Spokane a month.

SPOKANE.—The U. S. Magnesite Company, organized July 3, has started shipping magnesite. The product is consigned to the Hillyard plant of the American Brick Company for manufacture into ferro-magnesite brick.

SPOKANE.—The American Wood Products Company here, is to be reorganized by H. J. Earnst and Eastern associates. The capitalization will be increased to $1,000,000, and a manufacturing plant, operating on a large scale, will be established in Spokane. Plant will produce turpentine, pine oil, light and heavy oils, charcoal, creosote and coal tar products. Purchase of extensive timber lands is also planned.

SPOKANE.—The C. G. Betts Company, makers of coal tar products, with a factory at Erie and Railroad Avenues, plan to add to their line the manufacture of napthalene flakes. Machinery for the recovery of this material from coal tar is now being installed, and will be in operation within 30 days. For a number of years the company has been utilizing coal tar from the Spokane Gas Works, in the production of creosote, roofing and paving tar, and preservative paint for metal and wood. The company's output has recently found a new demand in the mining enterprise near Spokane, for selective ore flotation, and the company is now using from 40,000 to 50,000 gal. of coal tar per month in its manufactures.

SUNNYSIDE.—The Potato Growers Association of Yakima Valley has indorsed the starch factory project in that city, and it is expected that work will start shortly.

TACOMA.—The Tacoma smelter of the American Smelting & Refining Company has gone on a straight 8-hr. day basis, with 9 hr. pay.

TACOMA.—The L. Y. Stayton Cement Pipe Factory here is being extended to double its present capacity. The plant has so many orders on its books that it is compelled to run 24 hr. a day. New improvements include building 70 x 200 ft., and 50 x 250 ft. extensions to either side of the main building, with installation of much new machinery. Concern is now working on contract for 60,000 ft. 24 and 30-in. concrete pipe for the American Lake cantonment. Company has shipped pipe to all parts of Washington and Alaska, and handles big government contracts. Plant is equipped to turn out pipe from 4 to 36 in. in diameter. The plant has been operating in Tacoma for more than 12 years.

WILKESON.—The 60 new coke ovens of the Wilkeson Coal & Coke Company here have been completed and placed in operation. The new ovens make a total of 160 ovens operated by the company. It has taken a crew of 20 men more than six months to complete the work, sandstone being used extensively.

Ontario

HAMILTON.—The Semet-Solvay Company has engineers reporting on a project to erect a $2,000,000 coke oven plant. The plant will be erected by the Hamilton By-Products Coke Ovens, Ltd. It will have a capacity of about 900 tons of coke a day, and 7,000,000 ft. of gas. Stypes inlet is the site that has been chosen.

Manufacturers' News

BIG CONSOLIDATION.—Plans are being completed for the consolidation of the National Carbon Company, the Union Carbide Company, and the Air Reduction Company, according to information obtained in banking circles. A new company will be formed, whose stock will be exchanged for the shares of the three corporations. The new organization is expected to have authorized capital stock of $150,000,000.

The Union Carbide Company has outstanding $20,966,600 stock, which, at the current market price of approximately $200 is worth close to $42,000,000. The National Carbon's outstanding capital consists of $9,965,000 common and $5,000,000 preferred, with a current market value in the neighborhood of $13,000,000. The Air Reduction Company has 125,000 shares without par value, which at 97 would be appraised at $12,125,000. The total for the three companies would be around $67,000,000.

The concerns make allied products. The Air Reduction Company was formed about a year ago to make oxygen and nitrogen from the atmosphere by the Claude process and also to manufacture equipment for welding metals.

PAPER-PULP PLANTS WANTED.—Communications have been received by the Forest Products Laboratory of the Forest Service from the Technological Museum of New South Wales, at Sydney, Australia, and from the Forest Research Institute of India, asking for plans and specifications and estimates of cost of experimental paper-pulp plants.

Mr. Richard T. Baker, curator of the museum at Sydney, states that an investigation of the pulping qualities of Australian hardwoods has been undertaken, and he desires to communicate with manufacturers of needed machinery. His address is: The Technological Museum, Harris Street, Sydney, New South Wales, Australia.

Mr. William Raitt of the Forest Research Institute and College of India, states that the branch of the service that he represents is contemplating a large extension of its practical work and that the installing of a plant for the production of paper pulp is among the projects undertaken. He desires illustrations and descriptive matter on the subject and invites estimates from manufacturers. He favors a drying machine on the Fourdrinier principle, but with no shake on the wire. The raw material to be used comprises bamboo and Savannah grasses digested by the soda method. The institute also intends to fit up small plants for the treatment of resins, gums, etc., cracking of oils, tanning extraction, and timber creosoting. Mr. Riatt may be addressed at the Forest Research Institute and College, Dehra Dun, United Provinces, India.

CAPITALIZATION OF NEW CHEMICAL COMPANIES.—The authorized capital of new companies formed in July for the manufacture of chemicals, drugs and dyes amounted to $10,215,000, according to a special compilation of The Journal of Commerce. This figure shows a marked increase from the total for June, which was $1,175,000, and has been exceeded in only five months since the beginning of 1915. The aggregate authorized capital of similar concerns organized in July, 1916, was $330,000 and in July, 1915, $4,950,000.

The total indicated investment in chemical, drug and dye corporations during the last thirty-one months, covering the period since importations from Germany have been cut off and the United States has been forced to depend largely upon domestic production of materials, is $217,569,000. Of this total, $52,760,000 represents companies organized in the first seven months of 1917. The average monthly authorized capital of these companies to date this year is $7,537,143, which compares with a monthly average during 1916 of $8,270,333, and during 1915 of $5,463,750.

FIRE PREVENTION.—The National Board of Fire Underwriters, 76 William Street, New York, has prepared for the Council of National Defense, and are mailing to a list of some 66,000 of the leading manufacturers of the United States a booklet of directions for the prevention of fire, under the title of "Safeguarding Industry," together with a show-card of fire prevention rules for employees.

This matter represents considerable labor and large expense. Its purpose is the highly important one of preventing fires in industrial plants which are working under the abnormal conditions of wartime emergency. President Wilson has given a signed statement for the cover of the booklet, as follows:

"Preventable fire is more than a private misfortune. It is a public dereliction. At a time like this of emergency and of manifest necessity for the conservation of national resources, it is more than ever a matter of deep and pressing consequence that every means should be taken to prevent this evil."

SARCO COMPANY, INC., of New York, have received orders for Temperature Regulators for each of the sixteen cantonment camps, as well as for the Selfridge Aviation Field, near Mount Clemens, Mich., and for the League Island Navy Yard at Philadelphia, Pa.

PSYCHROMETRIC CHART.—The Braemer Air Conditioning Company, Philadelphia, Pa., has prepared for distribution a psychrometric chart which should prove very useful in dealing with humidity and evaporation problems. The chart shows by curves relative humidity, dew point, absolute humidity, total heat per pound of air, volume per pound of air, and vapor pressure.

ELECTRIC FURNACES.—T. H. Watson & Company, Ltd., of Sheffield, England, who control the patents of the Greaves-Etchells electric furnace, announces the formation of an American company to handle the furnace business in the United States and Canada. The new company will be known as the Electric Furnace Construction Company, with head offices in the Finance Building, Philadelphia.

The American Company have just received awards for 6-ton equipments, to be installed in the United States Navy Yards at Puget Sound, Norfolk and Honolulu.

Mr. Frank Hodson, a partner of the T. H. Watson & Company, is now in this country to arrange the details of the new company, and will act as its president. Mr. J. Ryan will be general manager. Mr. Ryan resigned as eastern manager of the Snyder Electric Furnace Company on June 1 to take up his present duties.

EIGHT HUNDRED MESH SCREENS.—Whenever very fine material was desired, material finer than 200 mesh, resource had to be taken to bolting cloth. Stearns-Rogers of Denver, Colo., is at present putting out a metal screen which will handle material as fine as 800 mesh. Ordinary 200 mesh screening is electroplated with nickel In this manner 300, 400, 500 up to 800 mesh openings may be obtained by simply regulating the amount of nickel deposited. It is claimed that the deposit of nickel gives a hard and lasting surface, the only drawback being that the material is rather brittle. Some careful regulation of the conditions required in the electroplating operation will undoubtedly overcome this evil, as rather ductile deposits of nickel can be obtained in practice. These screens should prove of value in flour mills and in such metallurgical operations where the values lost are usually found in the very fine material, as for instance in the losses encountered in the metallurgy of tungsten ores where 66 to 80 per cent of all the losses are found in the materials finer than 200 mesh.

The Chemical Exposition

The third National Exposition of Chemical Industries, to be held at the Grand Central Palace during the week of Sept. 24, bids fair to eclipse the former gatherings. The initial exposition, held after the first year of the war, was an expression of an industry which was just finding itself in a fairly limitless horizon of possibilities. The sense of the best thought at that meeting was the crying need of an educated, appreciative and just state of mind on the part of the American public. This, happily, is in large manner becoming an established fact.

Chemists, as a whole, were quick to grasp the significance of the exposition idea, and several societies scheduled their regular meetings during the week of the second annual exhibit. The result was large and enthusiastic throngs of technical men in attendance, but with an inevitable duplication of effort and diffusion of attention.

This year the exposition holds the stage alone. Its remarkable growth will be evidenced by the wonderful collection of apparatus, machinery and products of interest to the engineer, and the imposing numbers of models and motion pictures for popular consumption. For such occasions not only furnish a meeting place for technical consultation and discussion of manufacturing difficulties, an assemblage point for the exhibition of the great natural resources of this land of ours which await the transforming touch of modern chemistry, but a place where the man on the street can get an idea of untold possibilities of science and an appreciation of its every-day application in promoting his welfare.

The Nitrate Supply Committee's Recommendations

Nothing is usually more instructive than the problem's formulation. Ten years ago, the question would have been: "Is the manufacture of nitric acid from air practicable?" As it was recently put up to the Government's nitrate supply committee (involving the decision on a $20,000,000 appropriation), the question was: "Which one of at least half a dozen different processes for the fixation of atmospheric nitrogen is the most practical one under present conditions for this country?"

The committee's decision, fully recorded elsewhere in this section, is in favor of synthetic ammonia, followed by oxidation to nitric acid. For the production of synthetic ammonia, the de Jahn process, a new process of the General Chemical Company, differing from the Haber process particularly in the use of a lower atmospheric pressure, is recommended. The decision involves the expenditure of less than $4,000,000, because the

first cost is low, the power requirements being apparently lowest of all processes under consideration, so that no hydroelectric development is to be taken into account.

It should be noted that entirely independently the same conclusion on the relative cost of the different processes is reached in Dr. Maxted's paper, published in our present issue, on the development of the modified Haber process in Great Britain. So far, so good. This independent check of the Nitrate Supply Committee's chief conclusion is exceedingly welcome.

Yet there remains a certain incongruity to be explained, in that an appropriation of $20,000,000 was made and less than $4,000,000 are to be expended. Does this indicate rash extravagance of Congress in making the appropriation and superhumanly virtuous restraint on the part of the committee? Hardly. A much simpler explanation is that those who pushed the $20,000,000 appropriation through Congress thought they could kill two birds with one stone. They figured that in accordance with most prominent European developments the solution of the problem of fixation of atmospheric nitrogen for the needs of this nation would necessarily be bound up with an important waterpower development requiring a large capital investment. This would have furthered two very meritorious objects: First, it would have solved the nitrogen fixation problem; second, it would have helped to relieve, at least somewhat, the present calamitous power situation in this country.

But the Nitrate Supply Committee, which was called upon to make the decision, decided that its only primary object was to select the most suitable nitrogen fixation process, and that the deplorable waterpower muddle was none of its business. As the one nitrogen fixation process most suitable for this country and for the present time, it selected synthesis of ammonia, and was particularly fortunate in discovering a new and highly promising process of American origin. Very probably this was the very best selection that could be made, and the committee and the General Chemical Company, with the chairman of its board, Dr. Wm. H. Nichols, and the inventor of the process, Mr. Frederick de Jahn, all deserve heartiest congratulations.

While the situation thus has its very bright side, don't let us now overlook the dark side. In view of the outcome, it was a mistake in the beginning to mix up the nitrogen fixation and the waterpower problems. The waterpower problem now remains unsolved. Yet, as reflected in numerous important contributions by prominent engineers and business men in the editorial section of this issue, the best interests of the whole nation require that it be solved in the near future.

Problems Before the Chemical and Metallurgical Industries

The universal and insistent demand upon metallurgical and chemical industries, the undercurrent common to all the special articles and interviews in this issue, is for *more production*. Petroleum reserves are steadily diminishing under an enormous consumption. A shortage of twenty-five per cent in the supply of sulphuric acid is imminent. A famine in electrical energy at the very center of electrochemical industry is depriving industrial and militant America of essential substances. The steel works are just drawing a long breath at the end of a panicky bull market, and the copper companies are fighting a multiplicity of strikes, which has made serious inroads into an already deficient output.

Many elements, working together, are necessary for the perfection of a going concern. First, capital. A review of the By-product Coke Oven and the Dyestuff Industry shows how untold millions will be forthcoming from prosperous America to finance permanent industrial expansion. Money may be had in plenty.

Brains are more necessary than dollars. The wonderful evolution of our metallurgical processes in the last forty years is a veritable wonder of the technical world, and a source of inspiration to foreign engineers visiting our country. Chemistry, too long stifled by foreign trade combinations, has leaped to the front from a firm foundation of correct technology. Educators are realizing that real pedagogic problems exist in smoky smelters. Brains may be had in plenty—they will be needed in plenty—and should be mobilized and utilized more wisely by the Government.

Materials are required to build and operate new capacity. Oil drilling is halting for the lack of casings, piping and other essentials. Sulphuric acid cannot be supplied for a lack of pyrite. Metal production waits on a supply of basic refractories and fuel. So far as such shortages are artificially produced by criminal profiteers traitorous to America, they can and are being eliminated by governmental action through big men and patriots. So far as shortage results from a lack of natural resources, the engineer can turn prospector, discovering new sources of supply, or turn experimenter, devising substitutes or developing more efficient utilization of present stocks.

Appears a labor shortage, real and artificial, real in that immigration can no longer furnish the man-power required to match our expanding plant capacity. Artificial labor shortages—strikes—are constantly being accomplished by vicious I. W. W. propaganda or the ubiquitous walking delegate. Real labor shortage can be best combated by the trained engineer—let him devise labor-saving machinery and devices, large and small. Managers should regard it as a patriotic duty to lend every encouragement to such work; they should visit around and see "how the other fellow does it." When our armies are mobilized, short-sighted men will be forced into two alternatives by a hard taskmaster called "war" to improve the process or curtail the output. Artificial labor shortage can best be combated by true Americans, the rank and file of laboring men, in their unions and in the shops. All honor is due to the patriots within the ranks of American labor who have realized their opportunity and are leavening the mass. Their work is pregnant with infinite good.

Any thoughtful engineer cannot fail to see opportunity beckoning him from every side. It is his day! There is a man's work to do! Let's go!

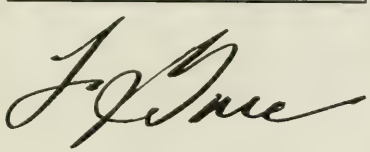
The Niagara Power Situation

By F. J. Tone

Works Manager, The Carborundum Company

One great anomaly in our war activities is that while we have speeded up every other national resource, Niagara remains throttled.

The part set for Niagara industries in the war program is a large one. They must supply the bulk of the ferro-alloys, the all-essential of the steel industry. Ferro-chrome is wanted for armor plate and projectiles. The army must have chlorine for gas shells, camp sanitation, water purification and for the Dakin solution. Explosive makers want caustic soda, potassium chlorate and chlor-benzol. Dirigibles require silicon for generating hydrogen. Destroyers want phosphorus for smoke screens. Abrasives, cyanides, aluminium, electrodes and many other products are urgently needed in the war game. The Aircraft Production Board has decided on the design of the standardized United States aeroplane motor. It will require quantities of ferrochrome for chrome steel crank shafts, chrome steel connecting rods and all parts subjected to the enormous strains of a mechanism weighing less than 2 lb. per horsepower. Quantities of aluminium will go into crankcases and pistons. The modern grinding wheel alone makes possible the finishing to limits of a fraction of a thousandth of an inch all parts of the aeroplane engine and thus the artificial abrasives of Niagara become the key to interchangeability.



To meet this war demand there is actually available 60,000 hp. less than in peace time. In 1916, 175,000 hp. was coming from Canada to the American side. Canada has now cut off half of this and the Ontario Government has authorized the expropriation of all the power which is now being exported to the United States. This complete embargo would cripple the making of war materials here, but the action is held up, it is said, only in consideration of probable reprisal on the part of the United States in shutting off coal going into Canada.

The action of Congress has been wholly inadequate to meet the situation. On June 30 Congress renewed for one year the permit to divert an additional 4400 cu. ft. of water, provided that it was to be used on generators already installed. Inasmuch as sufficient generating capacity is installed to utilize but a portion of this, the additional power is only 35,000 hp.

To help production of war materials the first relief measure should be legislation permitting the installation of emergency apparatus to use the entire amount of water allowed by treaty. Such installation could be made in twelve months. No power company however could undertake to install such apparatus without the assurance that the water could be used for a sufficient period to justify the investment. Therefore as a second relief measure, Congress should legalize the right of the power companies to use water for a fixed term of years. This would enable them to remodel their works so that the water now diverted could be used at the maximum head. The reconstruction work would cover a period of three or four years, but 300,000 hp. would be added to the power supply without diverting any additional water. It would save the nation 3,000,000 tons of coal per annum. A third measure should be the control of erosion at the apex of the Horseshoe Falls. The recession of the crest of the Falls is now 6 ft. per annum and the Horseshoe is rapidly becoming a deep narrow gorge gathering the whole river into a central channel. Invisible current deflectors or submerged weirs placed in the bed of the river above the Falls would deflect the water over the sides of a re-established Horseshoe and would make available double the amount of water now allowed by the treaty with an actual improvement in scenic effect and a saving in the nation's coal consumption of 16,000,000 tons per annum.

Looking to conditions after the war, it requires no prophetic vision to foresee the shifting of our electrochemical supremacy to Canada and Norway. By reason of Niagara power the United States has achieved during the past quarter century a supremacy in electrochemistry such as Germany achieved in the chemistry of dye products and fine chemicals. Remarkable as this development has been, it will no doubt be exceeded in the next quarter century. A score of rare elements and compounds of elements already utilized are waiting to be brought to the service of industry and he would be pessimistic indeed who would say that we will not have other developments rivaling aluminium, calcium carbide, fixed nitrogen and all the products of the electric furnace and the electrolytic cell that have revolutionized our basic industries. These advances will require the power of another Niagara or perhaps several Niagaras, and while we restrict water power development and glory in the amount of coal we burn, Canada is proceeding with a new development below Niagara which will give an additional 600,000 hp. Unless the awakening comes, Canada and Norway will control the electrochemical markets of the world.

Niagara Falls, N. Y.

The American Steel Industry

Kaleidoscopic changes are the normal thing in the American steel industry, hence there is not the least occasion for surprise that the war has effected great changes. The astonishing thing rather is that it required so many months after the war started for the realization to come to the trade that the industry was to be made very prosperous by the war. Many years ago the late James M. Swank, the great statistician of the industry, observed that it always had a chill or a fever. Many years later one of his great admirers coined the saying "prince or pauper," and that has become the common phrase, though as regards conditions existing at the outbreak of the European war Mr. Swank's terminology is by far the more precisely descriptive. The industry was experiencing a severe chill. It was familiar with periods of depression and low prices separating its periods of activity and large earnings, but there had been the unfortunate conjunction, late in 1913, of the period of activity and full production inaugurated in 1913 coming to a close just as a new tariff law was enacted, greatly decreasing the duties. The trade was not in a mental attitude to see that anything good could come from the war.

On the inception of the war a theory was entertained in some quarters that export trade would be stimulated. In terms of finished steel exported directly or consumed in the production of manufacturers, machinery, etc., that were exported, the steel producing countries, Germany, England, the United States, France and Belgium, were exporting to non-producing countries at the rate of somewhat more than 10,000,000 gross tons a year, the exports of the United States comprising less than one-fourth of the total. As supplies from the warring countries would presumably be shut off, here was a chance for heavy exports by the United States. It soon developed, however, that the neutral countries were unable to finance purchases to any great extent, and they were, moreover, in possession of fairly large stocks.

The steel mills operated at about 65 per cent of capacity during the first eight months of 1914, this including the first month of the war, and then their operations decreased rapidly until they were not over 40 per cent in December. Prices dropped to the lowest level since 1898. War steel orders did not begin to appear until about the beginning of 1915, but in the second quarter of the year they multiplied to such an extent as to be considered an important factor. Late in June one of the steel interests announced that it was undertaking a small addition to its capacity, and the incident was hailed as very significant, being the first of the kind for a couple of years. Millions of tons of new capacity have since been added.

The very moderate prices that were asked upon the first inquiries for large steel rounds for making shrapnel shells, 1.10c. to 1.30c., were in striking contrast with prices paid afterwards, in many instances higher than 4c. The inability to recognize at the outset of the war that a heavy demand for steel for war purposes would be created is likewise in contrast with the common appraisal when the prosperity began that it was due directly to orders of war steel. The fact is that the production of steel in 1916, minus all exports, both peace and war material, was materially greater than the domestic consumption in any year prior to the war. This increase was due chiefly to the enormous favorable balance in the foreign trade, produced only in minor degree by the exports of steel and manufactures thereof. The country as a whole was made prosperous, with full employment and plenty of money, hence it naturally consumed steel.

The present rate of production is about 33,000,000 tons a year, or at the rate of perhaps 90 per cent of capacity, operations being interfered with by shortages of labor and transportation. As representative of "steel production" the statistics of the production of ingots are frequently quoted, but they are really merely the record of the ingot scales, a portion of this tonnage going into scrap crop ends which goes back through the steel-making process. The production of rolled steel, the commercial product, is about 76 per cent of the ingot tonnage.

The reversal of feeling on the part of steel buyers, from the attitude of extreme dejection before the war started and the added fear that during the European war normal business conditions could not be expected, was so complete that it quite overshot the mark, and market prices were bid up to levels the producers themselves had never had the courage to expect. This process did not cease until June of this year, when finished steel prices were approximately quadruple the very low prices of December, 1914, and more than triple the average prices for either ten years or fifteen years preceding the war. A readjustment is now being forced, since the price situation was one that could not possibly continue for any length of time.

Conditions since the war started have not, on the whole, been favorable to the making of much technical progress. When it has been desired to increase capacity the new construction was expected to pay for itself, if at all, in a short time, perhaps not much more than a twelvemonth, and relatively little consideration was given to prospective earnings after the war. Hence time was the all-important element in new construction and divergences from accepted practice were not in favor. Despite scarcity of labor and materials many new records for quick construction have been made. As an instance, starting with a foundation previously provided, the Cambria Steel Company built a blast furnace complete in fifty-seven days, blowing it in on July 3, 1917.

The large amount of new construction of by-product coke ovens was not due directly to the fact that Germany was blockaded, causing a heavy demand for coke by-products. There were in operation by-product coking plants that were recovering scarcely any of the valuable by-products, and the first requisite would be to add the necessary departments to these already established plants. The new construction of by-product ovens was due rather to the general prosperity and the

ease with which the construction could be financed. Production of by-product coke in 1913 was 12,714,700 short tons, representing about 90 per cent of the existing capacity. The production in 1916 was 19,069,361 tons, representing the full average capacity for the year. The capacity at present is in the neighborhood of 24,000,000 tons a year, representing about 40 per cent of the country's coke requirements.

One surprise developed in the striving for maximum output at all points was the production of the blast furnaces. Based upon the output in 1912 and 1913, with allowances for the percentage of inactivity and the new furnaces completed in the two years, the available capacity for 1915 was not rated at more than about 35,000,000 tons a year, yet a rate of 38,000,000 tons was reached at the close of 1915, and the old furnaces have since made even a larger tonnage. With about three new furnaces completed in 1915, four in 1916 and nine thus far this year, the commercial capacity is probably somewhat in excess of 42,000,000 tons, but the rate of production is nearly 10 per cent less, chiefly on account of shortage of coke.

The largest annual outputs made by the various countries before the war, in terms of steel ingots and castings, made a total of about 75,500,000 gross tons, divided approximately as follows: Central Powers—Germany, Luxemburg, Austria, and Herzegovina—28.2 per cent; Entente Allies—England, France, Russia, Belgium, Canada and India—27.6 per cent; neutrals—United States, Italy, Sweden, Japan and China—44.2 per cent. Changes during the first year of the war included the transfer of Japan and Italy from the neutrals to the Entente Allies and the occupation by Germany of Belgium together with territory on which was located nearly three-fourths of the French steel-making industry.

In entering the war the United States occupied a peculiar position as to steel. The European countries had diverted nearly their entire steel output to the prosecution of the war, but the output of all belligerents was materially less than the present output of the United States, even though the latter is somewhat restricted as compared with its capacity. Thus the United States can prosecute the war vigorously and still have much steel left.

Germany and Austria have had no occasion to increase their steel output by new construction as they have had capacity in occupied territory to draw upon. France has added but little. England has added, perhaps, 3,000,000 tons to her ingot capacity. The United States, now has an ingot capacity of 50,000,000 tons or more, and is producing at the rate of 45,000,000 tons, against an output in 1913 of 31,300,000 tons from a capacity of 35,000,000 tons or thereabouts. With about 3,000,000 tons of new capacity in the United States in prospect of early completion, the world will have on its hands after the war an annual capacity of about 100,000,000 tons in steel ingots and castings, against a production of 75,500,000 tons before the war. About 18,000,000 tons of this will be in new furnaces in the United States and about 3,000,000 tons in new capacity in England. The balance is largely represented by the amount by which the production of the United States fell below its possibilities. All these figures are necessarily approximations, and no allowance is made for countries other than the United States having operated at less than capacity in former years of peak production.

It becomes clear, however, that the consumption of steel after the war must be approximately one-third greater than it was before the war in order to engage the present plants, and it is equally clear that the United States is much more interested in this fact than is any other country, for it is the United States that will have to find nearly all of the increase in outlet.

It is fortunate that steel is an article that is employed rather than consumed. The demand rests to an extent, of course, upon the general activity of the people, but in much larger degree it rests upon the inclination of capital to seek employment in undertakings which in the main have an element of risk in them. It is for this reason that the demand for steel, particularly in the United States, fluctuates so widely. The annual "consumption," or more properly speaking "absorption," has reached as much as 600 pounds per capita. Nowhere else has the proportion been anything like so large.

The war is being waged to make the world safe for democracy. It will then also be safe for capital. Such was not the case before the war. For years previous, every time there was a depression in the world's business one of the causes assigned was the fear of Europe becoming embroiled in a war. Even with no distinct prospect of war there were many regions in which it was altogether unsafe to invest capital even though the promised returns, safety being granted, were very large.

One can rest assured that after the war, in the new and better world it thrills us to think we are making sacrifices to create, there will be almost unbounded opportunity to employ steel in new ways. In addition to this there will be much steel required for reconstruction. It is a question of whether capital can be found for the work, but in the last analysis what is commonly known as "capital" is not a fixed thing. It is largely the creation of confidence, and confidence begets credit, which is closely akin to capital. In the new order of things everyone will work and will work hard. The world will have learned more of how to do things and do them quick, for the war has taught much with respect to construction work.

The United States can do either of two things. It can isolate itself with a tariff wall as it did after the Civil War, or it can employ scientific tariffs designed to encourage imports of things we need and encourage exports of things we can spare. Adopting the latter alternative it must undertake to finance, even in some cases to operate, many of the projects upon which it must depend for an outlet for a part of its increased steel production. The domestic consumption may also be expected to be materially larger than at any time previous to the war.

Petroleum

In an interview with Mr. A. C. Bedford, President of the Standard Oil Company of New Jersey, on September 12, Mr. Bedford said:

Before the war the demand for petroleum products was rapidly growing. It led to the prediction that the era of coal was giving way to the era of oil. Inventive and scientific genius had discovered many uses for crude oil derivatives with the result that the world was beginning to realize the economic value and diverse uses of petroleum.

Take gasoline, for example. It long had been a product which was regarded as of little value. Then came the invention of the internal combustion engines and its adaptation to the automobile. How the automobile has increasingly called for gasoline is shown by the fact that in 1899 there were 10,000 cars and in 1905, 85,000 cars. Then the numbers jumped rapidly, as, for instance, from 1,253,875 cars in 1914 to approximately 3,500,000 on the first of July of this year. The production of gasoline likewise jumped from over 6,000,000 barrels in 1899 to about 45,000,000 barrels in 1916. Thus the invention of the internal combustion engine greatly changed the problems of oil refining, for gasoline has now become one of the most desirable of crude oil products.

With this increasing demand for gasoline and other products, there developed an increasing call for crude oil for refining purposes. The total consumption of crude oil in 1904 was 117,000,000 barrels and it rose steadily to 324,375,503 barrels in 1916. Up until a few years ago, however, consumption by no means followed closely on the heels of the total production. Here are figures that show how the demand for crude oil has become greater than the available supply in this country:

Total U. S. Crude Production	Total Consumption of U. S. Crude
1914....301,527,000 bbls.	1914....265,762,535 bbls.
1915....302,989,533 bbls.	1915....281,104,104 bbls.
1916....308,272,519 bbls.	1916....324,375,503 bbls.

These figures represent "marketed production," *i.e.*, the amount of crude recorded as passing through the pipe lines last year (300,767,158 barrels), *plus* the amount withdrawn from storage, *i.e.*, from supplies previously stored in the field (23,608,345). In addition to these figures, almost 23,000,000 barrels of Mexican crude were imported and consumed in 1916, and over 16,000,000 barrels in the first six months of this year. There are not available to-day tank steamers enough to bring any material increase in these importations.

The latest figures taken from published sources of information for 1916 production, 308,272,519 barrels, prove somewhat better than the earlier estimates, and during the present year, from figures available for the first six months, the U. S. production of crude was on the basis of about 312,000,000 barrels annually.

But the consumption has been going on at the rate of approximately 330,000,000 barrels for the year. The supplies of crude oil in field storage and with the pipe line companies has consequently continued to decrease in spite of new production (of which more will be said later). The amount of petroleum stocks in storage has decreased from 174,370,500 barrels on January 1, to 164,590,942 barrels on July 1, a reduction of 9,779,558 barrels. This reduction, however, is largely in the crude stocks in California.

The war has added still further to this demand for oil production, coming as it did on top of the normal development of the automobile, the aeroplane, the naphtha launch, the farm engines, and the fuel-oil burning ships which already were making a big call upon the supply.

The necessity for oil supplies for the prosecution of the war has been a heavy drain upon the United States. This is due to the fact that the revolution in Mexico prevented the proper development of those fields. Then came the destruction of the Roumanian oil fields. The Allies have been calling for more and more oil products every year.

The export of gasoline in 1914 was $4,193,853 barrels, which increased to 5,632,182 in 1915, and then to 7,120,000 last year. Now comes the United States government with increased demands for gasoline for submarine chasers, aeroplanes, trucks and tractors, and many other purposes. It is estimated that the demands for the present year for gasoline will amount to more than 50,000,000 barrels.

Refiners, with their capacity enlarged until to-day they are handling about 330,000,000 barrels of crude oil in the course of a year, have done much to meet this situation. They have employed the best scientists and the best experts, who have developed means of extracting more than the ordinary amount of gasoline from crude oil by the invention of methods for cracking the heavy oil and refining it into gasoline. Herein the refiners have proved of immense value to the country and to the Allies in prosecuting the war, because they have at the expenditure of much capital provided the means for turning out the needed gasoline.

Had it not been for the introduction of the cracking process, the supplies of gasoline would long ago have fallen short of the amounts that actually have been required and used.

Another way of increasing the supply of gasoline is by the extraction of it from casinghead gas and natural gas. This industry is being developed and this year approximately two and a half million barrels of gasoline will probably be produced from this source. It is likely that more will be produced next year.

The demand for gasoline next year probably will exceed 55,000,000 barrels. That means it is necessary to produce still more crude oil; and here is the grave situation.

Despite the fact that the prices of crude oil have almost been record-breaking, and, therefore, offered good inducements to the prospectors and owners of wells to drill wells and turn out as much oil as possible, the figures for the first half of 1917 show that the number of wells drilled were 10,564 with an initial production of 692,718 barrels. In the first half of 1916,

12,658 wells were developed with an initial production of 800,266 barrels.

Thus, even with what seemed to be alluring prices for crude oil, the new production this year was less than the corresponding period last year. There are several reasons for this. First, there has been an increasing scarcity of casing and drilling materials caused by the demands upon the steel and iron mills for war production and their inability to supply the oil well drillers. The price of tank steel has almost been prohibitive. Next, the price of labor in the oil fields has also greatly increased. There has not been the profit to the oil producers that the public has ordinarily supposed, because the high price of materials and labor has added tremendously to the producing cost.

A general survey of the situation leads to the conviction that in order to produce the amount of crude oil needed, it is necessary to encourage more drilling and to find new fields of oil. To do this, it is necessary to pay prices for crude oil that will provide a reasonable profit to offset the high prices now paid for labor and for drilling materials. It is necessary also to make arrangements so that there will be a supply of pipe and casing. If this is done, the oil situation will speedily adjust itself. The supplies of petroleum which old Mother Earth still holds hidden are almost incalculable, but they are there to be drawn on if the proper effort is made. And with the capacity of refineries already enlarged to meet the increased requirements, and improved methods of refining to insure the maximum extraction of gasoline from the crude, all that is needed is—to get out the crude.

The Nitrate Supply Committee's Final Recommendations

The fixation of atmospheric nitrogen for the purpose of national defense has been the subject of extended and extensive official investigations during the past year. Section 124 ("nitrate supply") of the National Defense Act of Congress of June 3, 1916, authorized an investigation into the best, cheapest and most available means for the production of nitrates by water power or any other power that may be best and cheapest. To permit rapid action in backing up the conclusions reached in this investigation, Congress appropriated $20,000,000. The scientific investigation was in the hands of technical committees appointed for this purpose; the collection of all possible further information was in the hands of the special agents.

One of these agents was Mr. Eysten Berg, who visited Europe and submitted a report. Another of these agents was Dr. Charles L. Parsons, Chief Chemist of the Bureau of Mines, Interior Department, who, in the course of his investigations, visited the noted plants of Italy, France, England, Norway, and Sweden during the fall of 1916, and was able to give in his reports a most valuable summary and comparison of recent progress and conditions in the nitrogen-fixation industry at home and abroad, elaborated by extensive statistics of a confidential nature.

The first committee of scientists and engineers was appointed at the request of the Secretary of War by the president of the National Academy of Sciences in co-operation with the American Chemical Society, and consisted of Arthur A. Noyes, chairman; L. H. Baekeland, Gano Dunn, Chas. H. Herty, W. K. Lewis, M. I. Pupin, Theo. W. Richards, Elihu Thompson and W. R. Whitney.

This committee was succeeded and its work continued by a new committee—the "Nitrate Supply Committee"—appointed by the Secretary of War, and constituted as follows: Chief of Ordnance William Crozier, U. S. A.; Chief of Ordnance Ralph Earle, U. S. N.; Chief of Engineers Wm. M. Black, U. S. A.; F. W. Brown, L. H. Baekeland, Gano Dunn, Chas. H. Herty, Wm. F. Hillebrand, Arthur A. Noyes, Chas. L. Parsons and W. R. Whitney.

Of the progress of the investigation very little was heard during the past year, until it became known some weeks ago that the final decision reached was to put to immediate use less than $4,000,000 out of the total of the $20,000,000 "nitrate supply appropriation" of Congress until further information was given out by the Secretary of War at the end of last month. He first gave the details of the conditions as to the work to be undertaken at once by the Government, and second, published several reports in abstract written by Dr. Charles L. Parsons, chief chemist of the Bureau of Mines, as special agent.

The principal feature of the final recommendations of the committee, as indicated by this statement, is the manifest conviction that under the conditions now existing in this country those nitrogen fixation processes are most suitable which require the least amount of power. For this reason the committee does not favor those processes which have assumed greatest commercial importance in Europe in connection with immense hydro-electric developments. This explains at once why less than one-fifth of the total $20,000,000 appropriation of Congress is to be used up—there will be no large expensive water-power developments.

> The final recommendations of the Nitrate Supply Committee are as follows: that out of the total available nitrate supply appropriation of $20,000,000 a sum of $3,000,000, be placed at the disposal of the War Department to be used in building a synthetic ammonia plant, employing the process of the General Chemical Company, and of a capacity of 60,000 pounds of ammonia per 24-hour day, the plant to be located in a region where land, water, coal, and sulfuric acid are cheaply available, where good transportation facilities exist, and where the proposed new powder plant of the Government can be properly located. In the opinion of this committee all of these conditions just enumerated are best fulfilled by a location in a southwest Virginia or contiguous region.
>
> That out of the $20,000,000 appropriation a further amount of $600,000 be placed at the disposal of the War Department to be used in building a plant for the oxidation of ammonia to nitric acid and the concentration of nitric acid, of a capacity equivalent to 24,000 pounds of 100 per cent nitric acid in a 24-hour day, the plant to be located in the neighborhood of the synthetic ammonia plant and the proposed new powder plant of the Government.

That experimentation looking toward the industrial development of the Bucher process for the production of ammonia be at once proceeded with, and further that, contingent upon a satisfactory arrangement with the Nitrogen Products Company, a sum not to exceed $200,000 be allotted for this purpose out of the $20,000,000 nitrate supply appropriation.

That out of the $20,000,000 nitrate supply appropriation, $100,000 be made available for the active prosecution of investigations of processes for the industrial production of nitrogen compounds useful in the manufacture of explosives or fertilizers, and that these investigations be planned and supervised by the War Department.

That, in order to increase the production of ammonia and toluol, the Government promote the installation of by-product coke ovens by directing that priority be given in the production, delivery and transportation of the materials and parts needed in their construction.

That the decision as to more extensive installation of nitrogen fixation processes and water power development in connection with them, be postponed until the plants above recommended are in operation or until further need arises.

That the immediate accumulation and permanent maintenance of an ample reserve of Chile saltpeter not less than 500,000 tons is most urgently needed in this country.

The foregoing report having met with general approval, the Secretary of War directed the Chief of Ordnance of the Army to proceed to carry out the committee recommendations on the synthetic ammonia and nitric acid plants, and announced that for the present the consideration of development of large water-power installations which had been begun by the Inter-departmental Board (Secretaries Baker, Lane and Houston) appointed by the President would be suspended.

Pending actual developments, the Ordnance Department of the Army is proceeding as energetically as possible with the work intrusted to it, has made arrangements for taking over orders at cost which the General Chemical Company had placed for the necessary apparatus for the construction of a considerable plant for their own use, and thus gains considerable headway upon much of the apparatus as well as favorable prices. The J. G. White Engineering Corporation has been engaged for the remaining engineering work and the actual construction; the plans for apparatus are essentially complete, and designs for all of the buildings are very nearly completed as a result of work done by the engineers of the General Chemical Company.

One of the reports, dated Jan. 27, 1917, which Dr. Charles L. Parsons, chief chemist of the Bureau of Mines, prepared for General Crozier, gives interesting data on the arc process, the Haber process, the Cyanamide process, and by-product coke-oven ammonia.

Concerning the *arc process*, which is operated on a very large scale in Norway, it is said that in spite of the very low efficiency of the process, yet on account of the very cheap horsepower available in Norway and the fact that the raw materials cost nothing and are always at hand, nitric acid can there be produced by the arc process at a cost less than by any other commercial process.

The cost of horse power used for the production of nitric acid in Norway is less than $5 per horse-power year. The best estimates in my possession indicate that with horse power at $10 per horse-power year, the cost of finished strong nitric acid at the plant would be as cheap as by any other process now in operation. However, the low cost of producing nitric acid by the arc process is outweighed by so many other disadvantages that, in my opinion, the process is entirely inapplicable to the uses of the United States Government, and this opinion appears to be shared by all who have given careful thought to the subject. The cost of installing the arc process is high and it involves the use of an amount of horse power that seemingly is not available on the American continent within reach of the points where the nitric acid would have to be used.

Nitric acid is not economically transportable. As strong nitric acid it can be transported only if tank cars made of aluminium can be obtained, and aluminium is a metal that, for this purpose, has many disadvantages besides cost. The nitric acid might be transported mixed with sulfuric acid in iron tank cars, but this involves the erection of large sulfuric acid factories near to the nitric acid plant and a large addition in freight rates. Freight rates on such nitric acid as is transported are very high and must always remain high on account of the dangers involved.

The great difficulty that has faced the Norwegian plants from the beginning, namely, a market for their products, would in peace times be a serious obstacle to the operation of a large arc plant in the United States. An arc plant at its best involves the use of 2.33 horsepower years per ton of weak nitric acid. This means that a water power development of at least 50,000 horse power would be necessary for the peace requirements of the Government, and a development of 440,000 horse power would be required for war purposes. These figures are minimum figures on the basis of the relatively high efficiency reached in Norway. No installation should be considered by the Government of less than 75,000 horse power for peace requirements or 550,000 horse power for war requirements. If the arc process is to be used it would also be advisable to arrange for the production of explosives at the point where the arc plant was located. This would of course involve the transportation of all other raw materials needed, such as benzol, toluol, alcohol, acetone, glycerine, sulphuric acid, cotton, and other materials too numerous to mention, to the plant and the transportation of the finished explosives therefrom to the place of consumption. As these materials are highly combustible and for the most part carry high freight rates, it has been found necessary the world over to locate the plants intended for the production of munitions near to the point where the munitions are likely to be consumed.

Among the recommendations of this report is one for the reservation of a supply of platinum.

As platinum is an essential for the oxidation of ammonia and of the utmost importance in the production of sulfuric acid and other supplies required for munitions; as there are no platinum reserves in the United States save a small amount obtained in the electrolytic purification of copper, gold, and silver ores; and as platinum is one of the precious metals with a value above that of gold, I especially recommend that legislation be asked which will conserve the platinum obtained each year by the United States mints, putting it in the vaults if necessary and issuing treasury notes against it as in the case of gold. Platinum would then be available for immediate use in case of need for the

production of nitric acid by the oxidation of ammonia and for the production of sulfuric acid so important in case of war. This platinum would be available without cost to the government and could, if desired, be used as a reserve for circulation, because even if applied to the purposes above mentioned there would be comparatively little actual loss of the metal itself.

The construction of a hydroelectric plant is recommended only if the arc or cyanamid process is used.

I seriously doubt whether hydroelectric power will be necessary or desirable three years from now for the most efficient process of fixing nitrogen, and accordingly I deem it unwise to install such hydroelectric power at great cost with the sole purpose of producing nitrogen. If, however, such water power can be utilized by the Government in the production of certain ferro alloys absolutely essential for ordnance and other munitions; can be sold to commercial companies who will take upon themselves the financial risk involved in the erection of plants for nitrogen fixation, under guarantee of cheap ammonia to the Government; or can be sold during peace times to companies requiring power for purposes which would allow instant requisition of the power by the Government in time of war without handicapping the supplies of other needed war material, the development of such hydroelectric power would be highly desirable.

A second report by Dr. Charles L. Parsons (April 30, 1917) is particularly interesting, for the data it gives on the new synthetic ammonia process of the General Chemical Company.

The General Chemical Company, through the chairman of its board of directors, Dr. Wm. H. Nichols, has offered to the Government the use of the de Jahn process free from any charge or royalty for the purpose of explosive manufacture, while for fertilizer manufacture a royalty of $5 per ton of 2000 lb. of fixed nitrogen in any form shall be charged. (This represents a charge of not more than 25 cents per ton for the usual mixed fertilizer.)

The de Jahn process has been developed in the past four years by the General Chemical Company for the synthetic production of ammonia by direct combination of hydrogen and nitrogen. Lower pressures are used in it than in the Haber process. It has been in successful operation on a large experimental scale with several small units for ammonia production, and with one unit larger than those supposed to be used in Germany with the Haber process. It is considered to be the least expensive and most easily installed of all processes investigated by the committee.

The General Chemical Company has also developed and brought to a commercial basis the production of a mixture of nitrogen and hydrogen from coke, air, and water, which will yield hydrogen at a cost lower than heretofore obtained in this country and probably lower than that obtained in Germany.

As to cost of construction and operation it is estimated that even under present conditions a 30-ton per day plant can be built for an expenditure of $3,000,000 and can be operated at a cost of not to exceed 4 cents per pound of ammonia produced, allowing $5 per ton of product for repairs and 12½ per cent of the cost of the plant for interest and depreciation. It is believed that the charges for repairs, interest and depreciation are excessive, as, together, they comprise more than 50 per cent of the total cost of the ammonia production. In the estimate $3 per ton of product is allowed for general expenses and overhead charges.

It is estimated that a smaller plant of at least 7½ tons per day capacity can be built at the present time for approximately $1,100,000, including land and buildings. Such a plant would yield 2700 tons of ammonia per year—equivalent to 8700 tons of 96 per cent nitric acid, assuming 85 per cent recovery.

The following table gives comparative construction and operating costs of the various comparative processes:

	Arc	Cyanamid	Haber	General Chem.[1]
Product	35% HNO_3	NH_3	NH_3	NH_3
Power required	10.5	2.2	0.2	0.2
Investment	$1,410 (a)	$440 (a)	$340	$300
Operating costs[2]	170	150 (b)	119	97
Product	96% HNO_3	96% HNO_3	96% HNO_3	96% HNO_3
Power	10.8	2.3	0.3	0.3
Investment[3]	$1,570	$670	$770	$720
Operating costs[4]	220	270	239	217

With respect to the Bucher process, Dr. Parsons mentioned that this new process has been developed by Prof. J. E. Bucher (described in this journal, Vol. XVI, page 315, March 15, 1917). The fundamental idea is to produce ammonia through cyanide as an intermediate product. The process is owned by the Nitrogen Products Company, and is used on an experimental scale in two plants at Saltville, Va., in a coal-fired furnace, and at Niagara Falls, N. Y., in an electric furnace. The president of the Nitrogen Products Company, Mr. Edward E. Arnold, who six months ago declined to go on record as to the future of the process, now unequivocally states that he considers the process a certain commercial success and a probable competitor with any other process for the production of fixed nitrogen. This company has offered to the Government the use of the Bucher process under conditions like those tendered by the General Chemical Company.

For the change of the ammonia into nitric acid two types of processes are available: the Frank Caro process and the Ostwald-Barton process. A third promising possibility is the oxidation of ammonia or cyanamid direct to ammonium nitrate in solution.

The present commercial efficiency and output by the Ostwald-Barton process is higher than by any other concerning which exact figures have been obtained. It is higher than the published figures for the Frank Caro process, but as figures for that process have been published only on a minimum basis, it is impossible to state whether a high efficiency of conversion and capacity of catalyzer has been reached by that process.

[1] Estimates on General Chemical Company process are based on present wartime construction costs. All other on normal prices.

[2] Amortization for cyanamid as charged by operating companies. Amortization for Haber 20 per cent of plant cost for repairs, interest, depreciation. Amortization for Arc and Modified Haber 12½ per cent interest and depreciation. $5 per ton of product for repairs.

[3] Except for Arc process, includes ammonia plant as given A, power additional, $10; oxidation and absorption, $140; concentration, $40; steam plant, $40.

[4] Except for Arc process, includes ammonia costs as given; oxidation, $50; concentration, $70. No allowance made for unoxidized ammonia.

(a) Power plant investment reckoned at $100 per horsepower.

(b) Cyanamid production, $122; ammonia from cyanamid, $28; total, $150.

The Colleges and Their Neighbor's Smoke

By Herman Schneider
Dean, College of Engineering, University of Cincinnati.

Davy Crockett was a great man, and he lived at the right time. He was a mighty individualist, and individualists were needed in his day. His favorite expression was said to be, "I'll move on as soon as I can see my neighbor's smoke!" And he did. By moving on, he and kindred spirits made it safe for us to settle down.

For settled down we are, with our neighbor's smoke all about us, and individualism a thing of vacation time only. We work together, talk together, progress together, or get out of the procession entirely. Even those super-individualists, the I. W. W., flock together.

Herman Schneider.

The great man of this day is the one who can attune his powerful individuality to the hazily forming ideas and ideals of a hundred million individuals; the one who can think nationally, feel nationally, and act nationally; whose neighbor's smoke speaks of mutual interdependence and stirs the imagination to the nation-wide to-morrow of all of us, rather than to the arm's-length to-day of himself. Whether your work is in iron or ice or putty or prunes or eatables or education, the statement holds. It sounds oratorical, perhaps, but all big things sound oratorical on the first statement.

Living to-day is like reading an old-time thriller. You never know what is going to happen on the next page; generally it is the unexpected that does happen. Prophecy is permissible and pardonable only as a form of individualistic blow-off—heredity must be heard—but the safe working basis is to assume the big fact that hereafter we, the people of the United States, will work together like a Roman phalanx. There is no *or, but,* or *if* to this. It is in the minds of the people, and that settles it.

Just what form of phalanx we shall evolve no one can tell. But we do know that the plan will shape itself around the idea that in this land all things must *work together* for good—the good of all of us. If that sounds too altruistic to you, if your individualistic tendencies buck at it, there is just one thing for you to do—get used to it. If you don't get used to it, if it doesn't become actually a part of your working organism, the phalanx will simply walk by you, perhaps over you.

In every line of activity the potential men who sense this notion to think nationally and to act nationally, will some day be the leaders in that activity. They will reach out to any smoke that has to do with their work, and coordinate all the fires into one intelligently working organism.

College professors love the word *autonomy.* Any daredevil who tries to monkey in a faculty meeting with the autonomy of the college departments is guilty of treasonable practices. So far as the colleges are concerned, the first difficult task to meet the changing order will be the coordination of all the departments into a closely knit organization. Following that, or while it is under way, will come the great revolution: bringing the colleges actually, not on paper, into the mills, the government, the farms, the railroads, and more especially into the very difficult problems to be faced in all of these human affairs. For in the new plan of having all things and all persons working together for good, the colleges will have a mighty task to perform.

It will be their job to train nationally; their training ground will be where things are done, and their equipment all that has educational value. The scientific problems will be many and difficult; but the problems of human relations will be more and doubly difficult.

To meet these in the new order, men must be trained at those places where *the problems actually exist,* and not where they have merely an academic interest.

This is the educational trend.

Davy Crockett is still paramount in some of our colleges, but you will see the day when the professor and his students and the producer and his fellow-workers will wonder how they got along without each other in their daily tasks. For we are at the dawning of a real democracy in which we shall think nationally, feel nationally and act nationally.

Cincinnati, Ohio.

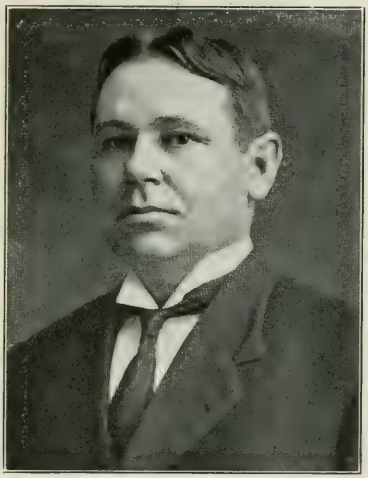
The Sulphuric Acid Situation

By Henry Howard

Chairman of the Executive Committee, Manufacturing Chemists Association of the United States.

There is probably no single article that is of more vital importance to the successful conduct of the war than sulphuric acid; without it, the manufacture of high explosives is impossible; without it the intensive production of food through the use of fertilizers also becomes impossible; large quantities are absorbed in the refining of petroleum, with the consequent production of gasoline and lubricating oils; and finally, it enters into the production processes of most chemicals whose applications in the arts and sciences are almost without limit.

Up to the beginning of the war, the sulphuric acid industry had had a steady and normal growth for many years, and the plant capacity was substantially in excess of the requirements of the country. The result was, that just before the declaration of war, many plants were not operating at anywhere near their full capacity. By April, 1915, this surplus capacity had practically all been absorbed, and three or four months later an acute shortage occurred which resulted in the construction of a large number of new plants.



Henry Howard

The production of sulphuric acid is, of course, largely dependent upon the supply of the raw material, namely, pyrites or sulphur. A discussion of the sulphuric acid situation involves a consideration of our available supplies of these materials as much as of the available capacity.

Up to the beginning of the war, nearly all the sulphuric acid made in this country was made either from pyrites or from the gas recovered from smelting sulphide ores, the sulphur from Louisiana and Texas being almost exclusively absorbed in the paper mills for the manufacture of sulphite pulp. Nearly all the acid made from pyrites within a reasonable distance of the Atlantic seaboard was made from imported pyrites, principally of Spanish origin, so that any interruption in ocean traffic would be likely to cause serious embarrassment to the acid manufacturers of the Eastern United States.

Up to January, 1917, there was no great difficulty in obtaining all the Spanish pyrites required, but almost immediately after the opening of the unrestricted submarine campaign, it became exceedingly difficult, if not impossible, to ship Spanish pyrites to this country. These conditions would have brought about a desperate situation in this country had it not been for the Louisiana Sulphur Company and the Freeport Sulphur Company. These companies, at the request of the Chemical Committee of the Council for National Defense and acting in a most patriotic manner, have come to the rescue of the acid manufacturers by supplying huge quantities of sulphur at prices only slightly above the normal pre-war prices for sulphur. It must be remembered, however, that these prices, low as they are for pure sulphur at the present time, are nearly double what the acid maker was formerly paying for his sulphur in the form of pyrites. The production of sulphur from the wells of the Gulf States is, however, not capable of immediate or indefinite expansion, for it requires huge installations of high pressure steam boiler capacity. It is therefore impossible to expect a prompt and unlimited quantity of brimstone from these regions.

In the meantime, the Chemical Committee of the Council for National Defense, through Mr. A. D. Ledoux, chairman of the Committee on Pyrites, has been carrying on negotiations with the English Government regarding the resumption of shipments of Spanish pyrites. These negotiations are now bearing fruit and substantial tonnages have been coming forward during the months of July and August with a number of vessels already chartered for shipments to be made in September. The Institute of Mining Engineers is actively engaged in the exploration of domestic pyrite mines, and some increase in supply from this source may be expected.

In general, it looks as if the existing sulphuric acid plants would be able to get the amount of sulphur and pyrites necessary to maintain continuous operation for the next six months or more, but at greatly increased prices. On the other hand, it would appear that the production of sulphuric acid will be inadequate to meet the demand during the balance of the war owing to the tremendous increase required for the production of fertilizers and explosives. Consequently, before next spring it will probably be necessary to arrange for the establishment of a preference committee to decide how the acid shall be distributed.

It has been estimated in Washington that the production of all grades of sulphuric acid, calculated as 50 deg. Bé., was 6,250,000 tons in 1916, and that requirements will be 8,000,000 tons in 1917.

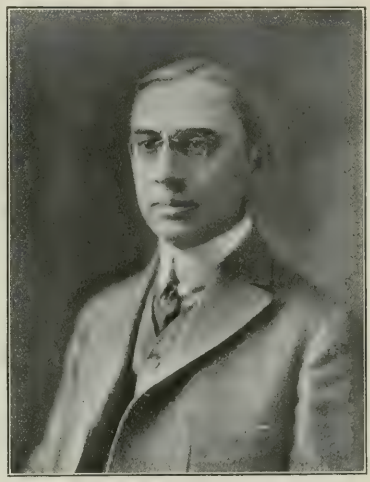
Predictions of any sort, however, are very dangerous to make in these days because of complex conditions. For instance, if the transportation systems are deranged by pressing war demands, deliveries of phosphate rock will slow down. The increased demand of the fertilizer manufacturers for sulphuric acid then will not materialize.

The American Dyestuff Industry

By I. F. Stone

Vice-Pres., National Aniline & Chemical Co., Inc.

On the outbreak of the war there were but five American color producers, limited to the manufacture of the so-called "original" colors, direct dyeing cotton colors, and acid and chrome colors for wool and silk which they were able to manufacture successfully in competition with Europe. The chemical industry was then making full use of all the opportunities presented to it under normal conditions. They could not compete with the German manufacturers, first, because of the great advantage in capital, experience and everything that goes with a successful and enormous business; second, because it actually costs 44 per cent less in Germany to make colors than it does in the United States; and third, the domestic manufacturers are prohibited by law from making use of co-operative commercial devices such as pools, trusts, manufacturing and selling agreements such as are wholly lawful abroad and encouraged by their governments.



It may be interesting to briefly sketch a history of this industry from its first inception in this country. The first American aniline factories were established about 1875. By 1880 there were some ten factories engaged in the manufacture of these products, and it looked as though it would be a very successful industry. Unfortunately, however, in 1883 a new tariff law was passed, reducing the protection on colors to such an extent that the industry was no longer possible, and consequently most of the factories dropped out until there were only three engaged, carried on more or less by the ambition of their owners rather than at a profit. About 1898 another factory was established, and along about 1914 still another. Owing to the intense competition of the European manufacturers, especially the Germans, none of these factories were successful enough to make a complete line of colors, and were restricted to only a few which could be made to advantage in this country. Again, they were forced to rely entirely upon European manufacturers for their raw materials; in other words, the intermediates, and naturally the European manufacturers charged them such a price that they could not successfully compete with the finished colors of Europe, made from the same intermediate products purchased at a lower figure.

In 1914, therefore, the American firms were making hardly one-tenth of the domestic consumption, and that largely with imported intermediates. At the beginning of the war, it was of course impossible for the German factories to ship their usual quantities because of the fact that the government had taken charge of all means of transportation for troop movements. After a couple of month's interruption, however, comparatively regular foreign color shipments of about 75 per cent of the normal sales arrived until the spring of 1915, when they ceased entirely. This was, I believe, partly due to the action of England taking measures to prevent such shipments, and partly because the Germans were disinclined to sell when they could not get needed supplies like cotton and foodstuffs in return. In the face of this famine, most consumers were forced into part-time operation at great loss to themselves and their employees, or into lines which required little or no dyestuffs or such colors of American manufacture as could be had. In some lines, for instance, the hosiery and possibly the leather manufacturers, this can be done to quite a large extent, as they mostly use blacks and other dark colors which were manufactured comparatively largely here; that is, for hosiery, direct and sulphur blacks, and for leather, blacks, nigrosines and logwoods. These were made and could be obtained in the United States almost in the necessary quantities.

Unfortunately for the aniline makers, however, at the outbreak of hostilities an embargo was immediately placed upon intermediates, for reasons best known to the German government. These essential substances could not be previously produced profitably in America. Had it not been for a small and precarious local production of aniline oil and nitrobenzole, the American dye works would not have been able to continue. They immediately began making intermediates, as under those abnormal conditions it was not a question of price, but of ability to manufacture aniline dyes almost no matter at what cost, such was the demand. After some months a number of new concerns also started in business, chiefly making easily manufactured intermediates; before that time the established aniline works had expanded their regular products to such an extent that by the beginning of 1916 they were making about four times their former production of finished dyes.

As an illustration of the importance of the dyestuff industry in its relation to other American industries, it may be stated that the textile manufacturers, comprising their cotton, wool, carpet, knit goods, silk, cordage, shoddy dyeing and finishing branches, absolutely require a great quantity of dyes in their operations. Add to this the leather manufacturers and tanners, the paper manufacturers, the paint and color manufacturers, printing establishments, ink makers, shoe dressing man-

ufacturers and a hundred and one other lines which consume dyestuffs, and I think I could safely say there are upward of two million employees who are affected by any shortage in dyestuffs.

At the present time there are over 100 firms directly engaged in the manufacture of crudes, intermediates and colors, with a combined investment estimated at $50,000,000, producing a quantity of finished dyes greatly exceeding in quantity the entire consumption during 1914. The American works, led by the old established factories, are now producing practically a full line of basic, acid, chrome and sulfur colors, and in the future will be able to produce enough to take care of the demand, if the consumers are careful enough to make forward contracts so that the factories can be prepared with the necessary installations and raw materials. They are willing to increase their facilities to practically any extent as long as customers will support them by making contracts. As to future expansion, there is no reason why any properly equipped chemical manufacturing company in the United States cannot supply the same quality and amount of colors as we were getting from Germany. We have the raw materials, we have the ability and the skilled labor.

Fortunately, Americans have become alive to the advantages of the by-product coke oven, and the construction of such ovens has recently gone on apace, and the local production of raw materials is now ample for all the demands of the dyestuff industry. For instance, we are already independent of Europe in benzol, which will always find a ready market for its surplus as a motor fuel. Ample benzol has made it possible to manufacture phenol (carbolic acid) synthetically, which latter substance is produced in less proportion to the consumption than any of the chemicals occuring naturally in coal tar. Toluol is of more importance than benzol to the nation on account of its use in the explosive field rather than for its use in the manufacture of dyestuffs, and an increase in supplies in benzol brings increased supplies of toluol. More naphthalene and anthracene is being recovered and refined from the heavier portions of the distillate by a revision of the specifications for creosote oil, and no doubt more of these substances can be recovered by the by-product plants if the proper demand is assured at a price commensurate with the added investment and cost of manufacture.

German chemists probably have $400,000,000 invested in the dye industry. They do not intend, if they can prevent it, that the color industry get a sound footing in the United States. I believe they will resort to the extreme of price-cutting and unfair methods to kill off any competition with their own export trade. In order that we may understand and properly provide for this contingency the following should be considered:

The materials of the dyestuff industry are used in the coal-tar explosives industry as well as for coal-tar medicinals. Each of these three industries co-operate with the others to make full use of these materials; alone none can fully make use thereof nor succeed; the correct and proper utilization of these materials requires successful co-existence of all three industries in one and the same country.

It is further clear that the stability of a complete domestic chemical industry, in so far as it depends upon commerce, is bound up to a successful merchant marine and to an efficient foreign banking condition.

The color industry will require a plentiful supply of all chemicals, including the so-called heavy chemicals, all of which will, doubtless, be obtained from American sources.

It will also require quantities of all basic raw materials and intermediates derived from coal tar in practically chemical pure form. The war has greatly stimulated the manufacture of a number of these products, unfortunately mostly for use in explosives.

The manufacturers of intermediates and colors during the abnormal war conditions have been able to obtain an abnormal profit out of which they have built and paid for their factories. They are now therefore in the same financial position as the German factories.

The United States Government has finally discovered that in order to make this industry permanent it is necessary to give more adequate tariff protection, and a tariff bill passed in 1916 giving this additional protection allows the American manufacturers a very much better opportunity.

The American consumers have realized the importance of having an aniline industry in this country, and therefore they will undoubtedly give the preference to American-made products.

A first step toward the mobilization of all the factors of this situation has been taken by the amalgamation of several old-established concerns into one large company which will now be in a position to centralize productive effort and capital in all the steps from the mining of the coal, through the by-product plants, intermediate and chemical manufacturing, to color making, selling, and research.

To sum up briefly the whole question of the permanency of the American dyestuff industry, it is apparent from the above that with united factories capable of producing the necessary colors, an adequate tariff, a strong financial condition established during the war, and the preference of American consumers for American products, we have certainly insured the permanence of the American dyestuff industry.

The high prices charged by American manufacturers of colors are due to, first, the demands of the explosives industry, which uses the same raw materials, and second, the high rates of wages paid by the industry. Products will revert toward their normal levels when these other matters reach normal conditions. It is very difficult to say whether labor charges will ever revert to their pre-war basis, as the laboring people have been educated to a higher schedule of living, and it is doubtful if conditions will change much in this respect. I believe, however, that American consumers will be only too glad to pay labor everything it is worth, and consequently a higher price for colors than ruled before the war will be cheerfully paid by our consumers, if they are within reason, which they will be.

New York City

Electric Furnaces

By Francis A. J. FitzGerald,
Consulting Engineer
Fast-President, American Electrochemical Society

Although electrometallurgical furnace plants were increasing before the Great War the increase was not as rapid as it should have been. The increased production of electric steel showed that this development was slowly approaching the point it should have reached, but it was still relatively if not absolutely below the European level. The United States Steel Corporation had built a large Héroult furnace in its South Chicago plant, and had made a variety of products therein, but the expectations of many that a great number of these furnaces would be constructed were disappointed.

Since the war began, however, there has been an extraordinary increase in electric steel furnaces. Probably this would be even greater than it has been were it not for the difficulty of getting electrical equipment in reasonable time and also to the shortage of carbon electrodes.

Francis A. J. FitzGerald

The difficulty of getting an adequate supply of electrodes and reasonably prompt delivery is a good measure of the extraordinary increase in electrometallurgical plants. Before 1914 there was no difficulty whatever in getting an adequate supply of both amorphous and graphitized electrodes. Many standard sizes could be obtained immediately from stock supplies and any standard size could be obtained in quantity in six weeks' to two months' time; but at the present time electrometallurgical processes requiring amorphous electrodes are limited by the electrode shortage. The question of electric power, serious as it is, is not of the same nature as that of electrodes. The power question is largely one of price, and consequently on account of the enormously increased prices of electrometallurgical products it is now possible to pay power rates that would have been considered ridiculous before the war. In the case of electrodes, however, it is at present impossible to obtain prompt deliveries at any price.

It is a matter for regret, so far as steel is concerned, that there has not been a development of the use of the induction furnace or the Röchling-Rodenhauser modification in this country. Furnaces of this kind are used very largely in Europe and are of course independent of the electrode supply. On the other hand, it is possible that even if we had a number of these in use the shortage of magnesite would be troublesome.

One result of the war as regards electric steel-making seems to be pretty certain; no sane person will construct a crucible steel furnace plant hereafter. The pendulum is swinging from crucible steel toward electric steel, due to similar economic conditions which recently caused the culmination of Bessemer capacity.

The shortage in the graphite supply and in the German clays used in making crucibles, with the resulting poor quality and high price of crucibles has stimulated greatly the desire for a good electrically-heated brass melting furnace. So far as bronze and copper is concerned there seems to be a satisfactory solution in sight, some good reports have been made on the use of the Rennerfelt furnace for this work. But the melting of brass still presents a difficult problem. The successful use of any form of arc radiation furnace for this purpose seems doubtful, and we must wait to see what can be done as a result of Clamer's and Hering's work on induction and pinch effect furnaces, or of Gillett's experiments.

The ferro-alloy development has been astonishing and everyone seems to be rushing into the manufacture of ferrosilicon as a result of the sensational prices that have been quoted for that material. High prices have undoubtedly resulted in turning over the use of a good deal of furnace capacity hitherto used for calcium carbide manufacture to the production of this material.

Another most interesting development is the manufacture of ferromanganese in the electric furnace. This has often been considered in previous years, but the low price of 80 per cent ferromanganese has formerly made its electric production unattractive. Now, however, things are very different and this has stimulated the electric furnace method in a wonderful manner.

Another new and interesting development is the production of basic pig iron in the electric furnace using high-grade steel scrap as a raw material.

The increase in furnace capacity for the production of artificial abrasives has been enormous. This is, of course, largely due to the increased demand, but also to the cutting off of the supply of Naxos emery. The consequence is that electric furnaces making aluminous abrasives and carborundum, which produced 62 per cent of the total abrasives used in the United States in 1914, have further experienced a great increase in number and output.

Americans may well feel proud of the way in which their manufacturers have met this situation, but at the same time it is with bitter regret they see in this case the continued exile of this distinctly American development to foreign countries, caused by the folly of the Washington politicians in the matter of water power legislation.

Niagara Falls, N. Y.

Aluminium

By Jos. W. Richards

To write anything satisfactorily upon the past, present and future of aluminium in a few words is not an easy task. Most readers of this journal are familiar with the beginnings of the industry, about the time of the invention of the Bessemer process, the middle of the last century. But the great hopes of Deville were never realized, the infant industry in France remaining an infant for twenty-five years. The industry began to grow into a promising youth in 1890, with the rise of the Hall process, and reached manhood strength and development only with the beginning of this century. The center of the industry has moved from France to North America, and of the nearly 100,000 tons produced annually, the United States figures for approximately two-thirds.

Jos. W. Richards.

The sources of raw material, bauxite, have not changed much in many years. France has the largest deposits, and really still exerts a controlling influence upon the industry in Europe from her command of the raw material. Purification of the raw material is essentially a manufacturing chemical operation, and has developed largely in the United States, Great Britain, France, Belgium and Germany.

Reduction of purified alumina to metal is an electrolytic operation, requiring large amounts of cheap power. In this matter, countries like Canada, Norway and the Alps possess great advantages, and the final step of reduction gravitates toward these countries. Norway in Europe, and Canada in America, loom up as the future centers of aluminium production, but are dependent upon other countries for their supply of the raw materials. Most of the large companies are therefore international in scope, working the mines in one country, purifying the raw material in another, and producing the metal in still another.

As a war material, aluminium finds many uses. Aluminium time fuses for shrapnel are used in place of brass, several million having been put into shells made in the United States for the Russian Government. Several thousand tons of aluminium wire have been used in the point of the modern long-tapered rifle bullets—the copper-nickel sheath has a small pellet of aluminium inserted in its point, the remainder being filled with lead. This gives a flatter trajectory and increased accuracy of fire. Machine guns of the air-cooled type use aluminium radiators. The explosive "ammonal," consisting of powdered aluminium and ammonium nitrate, is being used in large quantities by all combatants in the present war. Aerial construction has absorbed large quantities of aluminium. Each large Zeppelin contains about 9 tons of aluminium framework.

There is no longer any question of the status of aluminium as an "every-day" metal. Its use for cooking utensils has made it a household friend, and this still figures as its largest potential use. In automobiles it is a necessity, and almost one-third of all that is made is thus consumed. It is now a common, useful servant of mankind in a thousand ways undreamed of twenty-five years ago. Its introduction into common use has been one of the great achievements of the nineteenth century.

Since the outbreak of the war it has become increasingly difficult to get statistics of any reliability concerning the course of the aluminium industry. Even the promoters of the industry in America profess ignorance regarding the development of the industry in Europe.

It can be assumed with considerable confidence, however, that the industry has prospered greatly and increased in output except in Switzerland and Austria. In these countries, the producing company is controlled by German capital and a larger part of the product was shipped to Germany, while the alumina consumed was obtained mostly from the bauxite deposits of the south of France. This source of supply of alumina has naturally been cut off by France, leaving the Central Empires dependent upon their own sources of alumina. The industry in the United States has meanwhile developed handsomely.

It is important to note that while recent quotations were 55 to 65 cents per pound for odd lots, during 1916 the Aluminum Company of America supplied the bulk of the domestic consumption at 27 to 33 cents per pound. This was in consonance with a policy to supply the old customers at the same rates as prevailed in 1915, unaffected by the European demand. The Aluminum Company of America deserves great commendation for the combination of good business sense and intelligent patriotism shown in thus sparing the consumers of aluminium in this country the great hardships which a narrower business policy might have imposed.

What of its future? Its use and its usefulness will continue their rapid rate of increase; it will become cheaper after the war, and will rank with the half dozen metals most useful to mankind. The present output of 100,000 tons yearly will reach 1,000,000 tons before the middle of the century, and in net usefulness to mankind it will stand beside copper and be surpassed only by iron and steel.

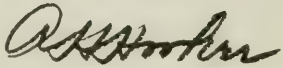
Electrochemistry

By A. H. Hooker

Technical Director, Hooker Electrochemical Company

The present war has emphasized the close relationship of chemistry to the ordinary necessities, comforts and luxuries of life, to say nothing of their vital importance in the materials of war, whether these materials be motor trucks, hospital supplies, guns, bullets or explosives.

The importance of the Niagara Falls industries to the present needs of our country, the calamities which might result from any curtailment of the power used by these industries, and the general public good which could result from a greater conservative use of this power, is best illustrated by a consideration of the uses made of some of the products so produced.



Phosphorus and phosphorus compounds are essential components in every match, the highest grades of bronze and copper alloys, in fire-carrying anti-aircraft bullets, and in liquid fire. Chlorate is equally important in the manufacture of matches and the fulminate cap, without which not a mine, cannon or rifle can be discharged.

Calcium carbide produces the acetylene gas for lighting the isolated country home, the small village and the automobile, as well as for flares, buoys and headlights. The cutting of armor plate, the building of our ships and steel structures, the repair of war's wastage requires the oxy-acetylene flame.

Carborundum, alundum and other electric furnace artificial abrasives are of the utmost importance in all the metal working industries. Without these the manufacture of motor cars, rifles, all kinds of machinery and equipment would be curtailed tremendously, and the expense of manufacture increased many fold.

Sodium is the basis for the production of cyanide, upon which depends the extraction of a large part of our gold and silver from the ore. Sodium peroxide is the starting point for hydrogen peroxide bleaching agents and disinfectants, and the source of oxygen for rescue helmets and hospital aid. That Chloroform is a necessity in surgery needs no argument.

Artificial graphite as electrode material is absolutely indispensable to the industries producing caustic soda, chlorine, and in the refining of steel. Every time a flash light gleams, a self-starter operates, or a telephone call is answered, think of the artificial graphite in the battery which makes it possible. As a lubricant deflocculated graphite fills a field which cannot be taken by any other material.

Caustic soda is essential for the manufacture of soap, the refining of petroleum and the production of gasoline. As a strictly war material it is required for the manufacture of nearly all explosives as a neutralizing and fusing agent. It is equally important in the production of synthetic dyes and medicines.

Chlorine is a many sided substance, beneficent and devilish in turn. As a sterilizing agent it purifies the drinking water of our cities and camps, preventing typhoid and other water-borne diseases. It is the basis of the Carrel-Dakin solution, that wonderful antiseptic dressing used on the battlefield. As a poison gas, we all know of its fiendish effects upon the soldiers in the trenches. Combined with calcium it forms bleach without which our paper mills and printing establishments would be bare of book and writing papers; it is also necessary in bleaching cotton fabrics. Chlorine, combined with such coal tar products as benzol, toluol and naphthalene, plays a most important part in our rapidly developing dye and explosive industry. As an example of this, we combine chlorine with benzol to produce monochlorbenzol. This on nitration and treatment with a caustic alkali becomes dinitrophenol, the intermediate from which may be made one of our most important and fastest dyes, sulphur black, or else by further nitration, converted into picric acid, one of the most largely used explosives.

This vital electrochemical industry, which now has its great center in Niagara Falls, is seriously threatened in its present development by the withdrawal of power which has been imported from Canada. The farther development of the industry, which is so widespread in its benefits to the entire population of the country, has been arrested or sent to foreign lands, all through lack of prompt conservation and conservative development of the power which is going to waste at our door.

A large increase in our present power development is beyond question possible without a particle of injury to the scenic beauty of the Falls. This development and the growth of these industries would be of untold benefit to the nation at large, and is of particular significance at the present time when we consider the vital importance of these materials to the successful carrying out of this war, and the conservation of coal and transportation.

It would seem that now, if ever, was the proper time to consider an increased power development and the proper means of obtaining the maximum development without injury.

Niagara Falls, N. Y.

Western Sulphuric Acid

By Lewis B. Skinner
Vice-President Western Chemical Company.

In these days of acute sulphuric acid shortage, the present and possible production of sulphuric acid in the Western States becomes an interesting phase of the national situation.

The volume of pre-war by-product acid was in part dependent upon the American spelter market—the foreign metal market was so well supplied from German-controlled works in Belgium operating on Australian ores that exportation was small. Again, freight rates make it practically impossible under normal price levels to transport either acid or ore any great distance by rail to the Eastern and Southern States, where the acid finds a ready market.

Lewis B. Skinner

The blende roasting plants are located in the Middle Western areas, where are large supplies of cheap coal and natural gas. The available zinc ores come mainly from west of the Mississippi and Tennessee, and freight rates have determined the economic location of the smelting plants near cheap fuel, largely in Illinois.

Just previous to war times there was an invasion by the Middle West acid-makers into the peak-price sulphuric acid area of Pennsylvania.

Since the war begun, two more large zinc acid plants have been completed in the Pittsburgh district. One of the operators, the United States Steel Corporation, had formerly absorbed a very large amount of acid from other makers. Ores from Australia failing to reach Belgium are finding a very satisfactory market at these Pittsburgh plants, and it would seem as if freight rates are such as to allow of a continuation of this ore movement even in normal times.

So much pressure had been brought to bear upon copper companies in Tennessee by the United States forestry officials that the smelters, several years before war times, had made a decision to manufacture acid with their sulphur smoke. The daily American production of 60 deg. Bé. acid had been increased some 1000 tons by these installations, which by the way were made possible only because their plants were operating semi-pyritic blast furnaces on pure ores, and in a region of large acid consumption.

Preceding the war, the demands of the Pacific Coast were not very large, probably no greater than a total of 150 tons of 66 deg. Bé. per day, and that of the Rocky Mountain area farther eastward no greater than 50 tons. Such a limited quantity was easily supplied by local acid plants operating with sulphide ores mined primarily for their metal content, and whose metallurgical treatment demanded a preliminary roasting or calcining operation.

Two large plants have recently been completed by two of the leading smelting companies in the Rocky Mountains. One plant at Anaconda, Mont., is expected to fill needs created by a new metallurgical process, and the other, near Salt Lake City, is expected to furnish acid for leaching oxidized copper ores. A third plant is being built by another smelter in Arizona. The Rocky Mountain area is therefore receiving its share of attention.

On the declaration of war, acid makers expected a greatly diminished demand, especially from the fertilizer maker, who would curtail his operation since he could get no more German potash. There was therefore much surprise when the spring of 1915 found depleted stocks and an ever-expanding market. Spurred on by this condition almost every manufacturer has increased his producing ability by various refinements in process and other expedients, until to-day I estimate there is a legitimate plant increase of 50 per cent over that at the beginning of 1915.

Every acid maker is wondering what he will do with his plant production after the war is over. Sulphuric acid is not a commodity like brick, lumber or slabs of zinc, that may be stored on the prairie without deterioration until some change of commercial conditions makes its purchase desirable. A number of small Southern plants which have been resuscitated by their neighboring fertilizer plants will doubtless again drop out of sight when the demand slacks off. The larger concern, with its interlacing of other operations and dependency on other commodities, will probably find it impossible to adjust itself so quickly.

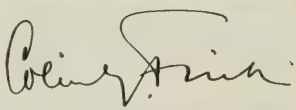
I find it difficult to refrain from the idea that the American policy of preventing any "getting together" of those engaged in similar lines of endeavor is a poor one. How much better from the political economy point of view would it be could those unfavorably situated and operated plants be stopped when they cease to have warrant for existence, and be reimbursed for their losses, thus leaving those more fortunately circumstanced to furnish the market requirements. Instead, all will try to peg along to the last, and be subjected to the purchasing agents' game of playing one against the other, with the result that the time will again come when the dollar invested in this industry (as has heretofore been indicated by statistics) shall see less return than if it were engaged in any other normal activity.

Tungsten, the Key Metal

By COLIN G. FINK, Ph.D.
President, American Electrochemical Society

The various fortunes of war are fickle, and it is a truism to say that victory finally perches upon the pennons of that side having the greatest resources of brains, men, and munitions. Since prehistoric times, however, there has been an unending struggle between various races of mankind, and in this has been a continual development of weapons and defensive armor.

Considering even the stone age, that tribe of men who had easiest access to the best deposit of flint and the necessary skill to work it was evidently easily victorious over its neighbors who had to rely upon the softer bone or horn weapons. Even the best development of flint swords and daggers and spears and arrow heads was unable to repel the invasion of another race armed with bronze side arms and shields. Yet the bronze age passed after centuries of groping metallurgy, while the ancient smith produced steel in his primitive forge and discovered how to harden it after being cunningly wrought.



The success of the disciplined Greek and Roman armies over the barbarian hordes was certainly due to their key metal, iron or steel, which tipped their javelins, ribbed their shields and formed their short blunt swords. Against such equipment of men and munitions the flights of savage flints and missiles were impotent. The middle ages witnessed the gradual perfection of the ancient war harness, culminating in the knight, armed "cap-a-pie," who now rides clanking through the pages of the story book.

Lead then became the key material, and the foot soldier came back into his own. The patriots of 1776 who tore down the leaden statue of King George tempered their patriotism with thrift, and sent the image back to its donors piecemeal in bullets.

A century later metallurgy again changed the equipment of armies upon the invention of the percussion cap, a capsule of copper held the fate of nations.

Most of the elements of the modern breechloading and magazine rifle were known at an early period, but they remained undeveloped for lack of means to do minutely accurate work. Tool development is a parallel phenomenon. Some essential properties of tungsten steels have been known for over fifty years—self-hardening steel tools were invented by Robert Mushet between 1860 and 1870. Not until the Paris Exposition of 1900, however, did the modern era in tool steel begin; then Taylor first exhibited to the astonished gaze of incredulous machinists the spectacle of a tool cutting so fast and deep that it delivered chips at a blue heat and in amazing quantities. Since that time the introduction of modern scientific shop management has been going on apace, wholly made possible by the use of these high-speed tools cutting four times as much metal as the best of the older carbon steels. Whereas in the wars of the past copper, tin and lead were, next to steel, the most important "martial metals," to-day tungsten alloyed as high-speed steel is the dominating factor. To deprive a nation of tungsten is to cripple its military power in time of war, and its industrial power in time of peace. Without high-speed steels, machine tools could not be produced nor operated in sufficient quantity to make the "seventy-five" and its thousands of shells, the rifle and machine gun and its millions of cartridges, nor could automobiles, farm machinery, ships or engines be replenished after the sword has been happily sheathed.

Germany was the only nation which properly appraised this situation in 1914. At that time, with characteristic thoroughness, she had a practical monopoly on the world's tungsten production. The mines of Burma, the world's most productive region, although in English territory, were controlled and operated by Germans and the ore shipped to Germany for treatment. The Cornish tungsten ore actually produced on the "tight little isle" was shipped to Germany for refining and then sold back to England.

At the outbreak of the war tungsten output actually declined as the German-controlled mines stopped producing, and it was not until the middle of 1915, after a year's hostilities, that England finally awoke to the importance of the situation by noting that no more tools were to be had.

Then occurred a violent speculative rise in price accompanying insistent demands of the war boards for more materials. When England at last realizes the need of a thing she goes after it, and the result to-day is that out of a total of 19,000 metric tons of tungsten concentrates (60 per cent WO_3) produced in 1916, England controlled and acquired 13,000 tons, or over two-thirds of the world's supply. Fortunately, the United States produced nearly 7000 tons of the best and purest of these concentrates in 1916, which is an earnest of our own possibilities—but it is important that these matters be well borne in mind and provided for against the time of necessity.

It may some day well be said that tungsten made democracy possible.

East Orange, N. J.

The By-Product Coke Oven

When, eight years ago, the Steel Corporation's new by-product ovens at Joliet, Ill., produced coke which made more iron per ton than standard Connellsville bee-hive coke, the doom of the wasteful bee-hive oven was sealed. Since that time, the advance of by-product coking has been a question merely of promoting a realization of relative coke values and of financing the relatively large plant investment required.

The outstanding feature of by-product coking development since the beginning of the war has been the confidence which American capital has manifested in advancing the tremendous outlay for permanent plant and equipment. With prices of all equipment soaring to undreamed-of levels, the complete plant costs twice or three times as much per oven as it cost five years ago, yet capital has shown no hesitancy. More by-product coking capacity has been installed or contracted for in the last three years than had been built in the twenty preceding years; the same capacity in bee-hive ovens would have required little more than one-quarter the outlay. Without an abounding faith in the value of by-product coke and in a lasting market for by-products, such a development would have been impossible.

By-product coking has doubled its capacity in the last three years. At the close of 1914 there was a capacity in by-product ovens for 15,000,000 tons of coke annually. Early in the year 1918, if present construction under way is carried to completion, there will be a capacity to produce 30,500,000 tons of coke per year. During these three years, 4037 ovens have been built or contracted for; their coal carbonizing capacity amounts to at least 23,500,000 tons per year, and the plant investment required has been over $100,000,000.

Notwithstanding this rapid development the United States will still be making in 1918 about half of her coke in bee-hive ovens, with entire waste of by-products. In 1914 the by-product ovens produced 32.5 per cent of the total coke, in 1915, 33.8 per cent, in 1916, 34.9 per cent and in 1917 probably about 40 per cent.

Of all the coal consumed in this country scarcely 7 per cent is carbonized with by-product recovery, while in Germany the corresponding figure is greater than 30 per cent. Germany wastes no by-products, and, due in part to that fact, she was better prepared for war in August, 1914, than any other nation.

American coke oven practice uses larger units than European. The rate of coking is also faster by virtue of high temperatures permitted by the use of silica brick. The American capacity per unit and cost per ton is thus much better. There has been a tendency however in recent years to limit the width to a balance between the most advantageous coking capacity and the wall-temperature required for good by-product yields.

America's opportunity for growth in coal by-products recovery, and in chemical industry based thereon, is greater than that of any other country. Our requirements of coke for iron production and our consumption of anthracite in house heating far exceed those of any other nation. As anthracite fails, domestic coke will replace it. By-product coke production therefore should not stop growing when the full demands of iron manufacture shall have been met.

Bee-hive coking, furthermore, will not necessarily be retained in any important degree in order to take care of fluctuation in the iron industry. The by-product coke plants can meet fluctuations in demand by varying their coking period and thus their rate of output. An excess of coke output also can be stored or disposed of at moderate prices for outside fuel purposes, in order to avoid shutdowns and consequent loss of gas and by-products. In this adaptability to steady operation with minimum labor and upkeep costs, and in the reliability and regularity of its output, lies much of the secret of success of the by-product coke oven.

The war has created an immense demand for toluol and benzol—the raw materials for the modern high explosives tri-nitro-toluol and picric acid. From a production of possibly 7,500,000 gal. of light oil in 1914, made at a dozen by-product coke plants operated by one company, the output has grown to approximately 60,000,000 gal. in three years—and all of the fifty-two by-product coke plants now operating in this country, with one exception, are equipped for recovery of benzol. Nearly 10,000,000 gal. of toluol per year are being made from this coke oven light oil.

Dyes and drugs, dependent on benzol, toluol, and coal tar crudes for their manufacture, require less than 10 per cent of the present light oil output, and are not likely to require more than that in this country for a number of years. When the war is over and the great demand for military high explosives has abated, benzol and toluol will find their outlet largely in motor fuel. Benzol containing 10 per cent toluol to lower its freezing point, is an excellent motor spirit, tried and proven, equal or superior to gasoline. With investment costs largely wiped out by war profits, benzol recovery plants can operate at a profit on gasoline prices.

Ammonia, in spite of a 100 per cent increase in production in three years, has maintained a rate of price advance commensurate with that of other commodities devoted to peacetime uses. The demand it enjoys for use in fertilizers, in the chemical industries, and in safety explosives is constantly increasing—faster than the supply can meet it.

In view of the almost unlimited field for the use of by-product gas, the rapidly widening application of coal tar and its products, and the prospect for the finding of new uses to absorb the present surplus of pitch and naphthalene—there can be no question of the disposal of by-products from the rapidly expanding industry.

Although the war has brought very large increases in the demand and price for certain by-products, this has not been the main factor in the recent remarkable growth of by-product coking. War profits alone, with their uncertainty of duration, could not justify the great investment in these large permanent plants. Rather has it been the confidence in the permanent value of the plants and their products, and the great influence of an abundance of available capital, supplied by the prosperity of the American nation.

A Reply to the Criticism of the Chemical Exposition

To the Editor of Metallurgical & Chemical Engineering

Sir:—In his letter to the editor of Metallurgical and Chemical Engineering, published on page 206, Sept. 1 issue, Mr. G. A. Roush apparently charges that because three exhibitors in the Second Exposition of Chemical Industries neglected to supply information or material requested, that the entire exposition was a failure. Such a statement is unjustified.

Mr. Roush has failed to appreciate the larger purposes of the exposition to show the progress made in the industries it represents, to indicate where progress can be made, how through efficient equipment and materials production can be increased or costs reduced, to show where and what opportunities await development, and how our natural resources can be made valuable and useful.

An exposition is the sum total of all its exhibits. In the Second Exposition there were 187 exhibitors. Through some apparently sinister circumstance three of these failed to fulfill the three particular things Mr. Roush had in mind in visiting the exposition. He seems to conclude from this that the entire exposition was a failure. This is the first occasion where we are informed that the sum is equal to any of its parts. Upon this same basis a college or university can be judged a failure because a graduate from one of its courses fails to come up to the standards of some individual.

This is the first criticism we have heard, and when sufficient consideration is given to the fact that over 80,000 people attended the Second Exposition, and were of the opinion that the exposition was a huge success from every standpoint, it cannot be denied that there is something radically wrong in this individual case.

National Exposition of Chemical Industries,
By Charles F. Roth, Manager.

Activities of an Impostor

To the Editor of Metallurgical & Chemical Engineering

Sir:—The writer thinks the industry should be advised that there is an imposter going about under various aliases who is a very plausible talker and is very well posted regarding various chemical companies and the men connected therewith.

It appears to be his practice to make an appointment by telephone, at the same time securing information which may be of value to him, such as the names of the company's officers, etc. After a short call, during which he talks familiarly about your business and your customers, he starts to leave and then casually requests the loan of ten or fifteen dollars until the following day, as he has to entertain some friends and is short of funds.

The writer was duly "touched" a short time ago by this man who was then masquerading under the name of West—this is the last seen or heard of this smooth gentleman.

Mr. West (?) is of medium height, with sparse hair tinged with grey and one of the middle teeth in the lower jaw is missing.

I might say further that one of our employees was "touched" for a loan by the same man, then using the name of "Lloyd" at the Chemical Exposition last fall. Unfortunately the writer learned too late that the party in both cases was the same man.

I hope this notice may prevent some possible future victim from being separated from his hard-earned "simoleons."

Silico-Manganese As a Steel Deoxidizer

To the Editor of Metallurgical & Chemical Engineering

Sir:—In line with your "An Opportunity for Metallurgists," I want to call to your attention the fact that the Pacific Coast is already preparing to supply the needs of manganese in the shape of a new alloy, silico-manganese. When I use the word "new" I do so guardedly. This alloy has been used quite extensively in Europe, and just to a very limited extent, prior to the war, in the United States.

The State of California holds extensive low-grade manganese deposits, high in silica and low in other impurities, which lend themselves readily to the manufacture of silico-manganese.

Silico-manganese of an analysis containing approximately 60 per cent of manganese and 20 per cent silicon, should be a most acceptable alloy to the steel manufacturers, since it supplies the two alloying metals, manganese and silicon, in proportions much desired by the steel metallurgists.

Silico-manganese, of analysis as outlined, can be obtained for a price considerably less than that of ferro-manganese, at the present time, and eliminates the double freight charges on ferro-manganese and ferro-silicon, as well as the double handling of these two alloys at the open-hearth furnace.

J. W. Beckman.

San Francisco, California.

A Suggestion on Patent Litigation

To the Editor of Metallurgical & Chemical Engineering

Sir:—There has been much said about patents, patent litigation, and its effects on industry. This is especially pertinent at present. What is needed now is something practical and applicable to war conditions. I will therefore offer my suggestion.

Suppose there is a real-estate litigation. I believe this has been proved by experience to be best handled before a jury in open court.

Now, a patent is a title to *intellectual real estate*—otherwise called invention.

It therefore seems to me that the way for our country to handle a patent suit might be to follow the rules promulgated for Federal practice by our Supreme Court in the fall of 1913 and to superimpose on this a jury of engineers, technologists and inventors, twelve good men and true and the peers of the litigants. Most of us

to-day know something of patent law, and with the evidence all prepared, with oral examinations so that the jury could tell by manner and voice which expert was trying to dodge and which was sincere, brief and earnest, and with a Judge asking questions and expounding the law, a final and just decision could be easily obtained in a minimum of time.

It seems that in the future, say for the next five or ten years, there will be extraordinary progress in invention, research and applied science, and that some truly efficient way to get results in patent litigation must be attained. If one-tenth the mental, spiritual and volitional energy that is now wasted in our country in fighting with each other and in the honest men fighting the grafters, could be applied in Flanders, K. W. would be dethroned, die Deutsche Republik formed, and aforesaid K. W. would be applying for a job as doorkeeper in our Wall Street District.

The above suggestion is given in a tentative manner in order to help settle a most important matter and one affecting the progress of our militant industries and our successes in arms. This war may be a long one. It will be won by inventions. Inventors, while not grasping, expect pay for their work. Above all, the uncertainty and resulting indecision that comes from our present troubles in the courts could be prevented.

In these premises, I might say that *au fond* our patent laws and patent practice are not so bad as usually regarded; in fact, are quite good. It seems to me simply that the ways and means are not well applied. Nor are champertous patent lawyers entirely unknown. What is needed right now is a strict enforcement of present rules and procedure, fewer patent lawyers and more good ones.

My suggestion might well take the form of a court of arbitration established by our national technical societies. The experience of Denmark with a court of arbitration of business men in general civil cases, would lend weight to the proposal. In this Danish court, the findings are so clear, so honest, and so intelligent that the decisions, though quick, are practically never appealed.

All the above is given in outline and in syllogistic form. For its brevity—and it may be considered even witty if brevity be the soul of wit—no apology is needed in a time when words are at a discount and only sell when they conduce to action.

WOOLSEY MCA. JOHNSON.

New York City.

Antimony in Zinc Electrolytes

To the Editor of Metallurgical & Chemical Engineering

SIR:—I am enclosing description of materials and a method for determining antimony in zinc electrolyte solutions which may be of assistance to other chemists, as we have used it successfully for three months. I believe it is considerably shorter than most of the methods being used on zinc solutions.

The materials required are:

1. Buechner funnel, large filtering flask, filter pump, H_2S generator, 2000 cc. beakers, 250 cc. beakers, fine filter papers (similar to Munktell's Swedish No. 0).
2. HCl and H_2SO_4 free from As and Sb; granular $KClO_3$, $HNaCO_3$, or HNH_4CO_3.
3. Na_2SO_3 solution, about 5%.
4. Pure Na_2S solution, about 3%. Iron may be removed by allowing the solution to stand two or three days in sunlight, and then filtering.
5. Standard iodine solution containing 2.12 gm. iodine per liter, dissolved with KI. 1 cc. = 0.0010 gm. Sb. Standardize against $Na_2S_2O_3$ solution (5 gm. crystals per liter; Cu × 0.9454 = Sb). If preferred, the iodine may be standardized against an antimony solution prepared as follows: Take 0.120 gm. of pure Sb_2O_3, and 200 cc. of the Na_2S solution and heat until dissolved, dilute to 1000 cc. and filter. 10 cc. of this solution contains 0.0010 gm. Sb. 50 or 60 cc. may be heated, treated with $KClO_3$ and HCl and finished exactly like the assay, as detailed below.
6. Starch indicator: Take 500 cc. of a cold saturated solution of NaCl, filter, add 100 cc. of 80% acetic acid and 3 gm. of starch. Mix cold, heat and boil until nearly clear. Add about 30 cc. water, cool and place in a bottle. This solution will keep indefinitely.

The following is the method of making the determination:

Take 1000, 1500, or 2000 c.c. of the solution to be analyzed, add enough H_2SO_4 to make about 10 per cent acid by weight, heat to 80 deg. or 90 deg. C., and pass in H_2S for 30 to 40 minutes. Filter by suction on Buechner funnel, using double filter papers. Wash well with warm H_2S water acidified with H_2SO_4, to remove all zinc.

Remove the filter paper, fold it as usual and place it in an ordinary funnel, with one fold extending diametrically across to expose all of the precipitate. Wash with about 30 c.c. of the hot Na_2S solution, at first pouring part of filtrate through the paper again. Wash twice with hot water. The CuS remaining on the filter may be dissolved in small volume of hot 1:1 HNO_3 and copper determined by the iodide method. For solutions containing much copper, the paper containing the Sb_2S_3 and CuS is best boiled with Na_2S solution and filtered on a separate paper (S & S No. 597).

Heat the filtrate nearly to boiling, add about 0.2 gm. $KClO_3$, stir to dissolve, add 15 c.c. of strong HCl and boil for a few minutes. Allow the solution to cool one minute, add 5 c.c. of the Na_2SO_3 solution, and boil for 5 minutes. Allow it to cool one minute, and treat again with 2 or 3 c.c. Na_2SO_3, and boil. Repeat this operation once more and then boil 30 minutes to remove SO_2. (Repetition of this reduction is almost always necessary, especially if more than 0.005 gm. Sb is present.)

If more than a trace of arsenic is present, the solution should be evaporated to 10 c.c. to remove it.

Cool the solution, make it slightly alkaline with ammonia, then slightly acid with the starch indicator containing acetic acid. Cool again, make up the volume to about 100 c.c., add an excess of $HNaCO_3$ or HNH_4CO_3, and titrate immediately with iodine to a permanent blue color.

With care and the use of pure reagents, the limit of error should be less than 0.0003 gm. of Sb. Complete assay requires less than 3 hours.

For high Sb, it might be well to add a little tartaric acid after the first treatment with Na_2SO_3, but we have never found it necessary.

In working out this method, much assistance was obtained from Scott's Standard Methods of Chemical Analysis (D. Van Nostrand Co.), Prescott and Johnson's Qualitative Chemical Analysis, and Low's Technical Methods of Ore Analysis.

Western Metallurgical Field

Smelter Investigation in Colorado

One of the "set pieces" at Colorado's legislative sessions for some years past has been a bill providing for the investigation of smelting concerns doing business in the State. Generally, it has been conceded that these measures, in the main, have been directed against the American Smelting & Refining Co. by legislators from the mining districts, who introduced them largely for political effect and for home consumption. In any event, none of them ever became law, and all met the customary finish in committee rooms. All were inspired by the vague notion that the smelter trust was robbing the miner in high treatment charges; and the legislators usually took their cue from a few shippers of small consequence, who, however just their cause, were not sufficiently conversant with the business to analyze it and get to the root of the matter. This is not to say that there were not reasons for dissatisfaction, for there were; but the proposed remedies were poorly conceived, by men who failed to recognize, first of all, that smelting is a highly technical business, which cannot be legislated upon without some knowledge thereof. Further, the industry is in the hands of comparatively few men, so that knowledge of its inner workings is not widely spread.

It was almost a foregone conclusion that the Colorado legislative assembly this year would pay its usual respects to the smelting industry in the form of a bill for an investigation of the buying and selling of ores. Two bills were introduced, one of which was better than the other in that it recognized the technical nature of a sound investigation, and proposed a committee of experts to conduct the same. The bill finally adopted was a combination of the features of each. It provides for the appointment of an investigating committee of five, comprising two Senators appointed by the President of the Senate, and three Representatives appointed by the Speaker of the House. This committee is charged with fully investigating "the buying, selling, exchange, refining, treatment, smelting and reduction of metalliferous ores or ore concentrates, the charges, rates, schedules and returns therefor; and shall cause to be filed with the Public Utilities Commission of this State, on or before the first day of January, 1918, its complete report and findings in writing, containing such recommendations as it shall deem appropriate in the premises."

The committee was authorized and empowered to conduct hearings, subpoena witnesses, and compel the production of records and documents. The bill carried an appropriation of the sum of $15,000 to carry out its purposes.

Obviously, the weak feature of the act is a politically appointed committee, because the public has no confidence in such a committee appointed to investigate a technical matter. Herein the bill was poorer than the one for which it was substituted. The committee appointed comprises Senators Siewers Fincher and William J. Candlish, and Representatives A. P. Ardourel, D. J. McDonald and H. P. Nagel. Realizing, perhaps, the lack of technical knowledge in the committee as a whole, it secured the services of Mr. O. R. Whitaker, consulting engineer of Denver, to review its findings and aid in preparation of the report. The selection of Mr. Whitaker will place the stamp of integrity on the conclusions drawn from the data furnished him by the committee, and it is to be hoped that the information is complete.

It is not unlikely that the report will criticize the smelters in some respects and exonerate them in others. Whatever the result, it is almost certain that the entire affair could have been avoided by a more liberal policy of publicity on the part of the smelters in years past. It has seemed as though the American Smelting & Refining Co. has been particularly dense in failing to get the spirit of the times, and slow to see the wisdom of explaining many features of its business to those on whom it was dependent for patronage. Admitting that many features of the smelting business are not understood, even by those deeply concerned, there exists the greater reason for that friendly spirit of confidence and co-operation that so many corporations have found profitable. A campaign of education on the part of the smelters for the purpose of enlightening miners on some of the more abstruse features of contracts, and a policy of simplifying and clarifying the method of computing ore values, would tend to make friends. This would be a big accomplishment, because in the last analysis the smelters' great lack is friends in sufficient preponderance to nullify any agitation for an investigation. Taking the mining public into their confidence would be good business, and perhaps one effect of the present investigation will be to educate the smelters to such a policy.

Canadian Mineral Production

The Department of Mines of Canada has issued its preliminary report of the mineral production of the Dominion for the calendar year 1916, showing a total production of $177,357,454. This is an increase of $40,248,283, or 29.3 per cent, over that of 1915. The previous maximum production was $145,634,812, in 1913. The report cites the progress made during the year in establishing and increasing smelting and refining capacities, notably the electrolytic zinc and copper refineries at Trail, the construction of a nickel refinery at Port Colborne, Ont., the production of metallic magnesium at Shawinigan Falls, ferro-molybdenum at Orillia and Belleville, metallic arsenic at Thorold, and of

stellite, the hard cobalt alloy for high-speed tool steel.

Nickel was an important product of Canada during 1916, being derived from the ores of the Sudbury district, supplemented by the recovery of smaller amounts from the silver-cobalt-nickel ores of the Cobalt district, and a small tonnage of nickel ore from the Alexo mine in Temiskaming. The Sudbury and Alexo ores are reduced in smelters and converters at Copper Cliff and Coniston to a matte containing from 77 per cent to 82 per cent combined nickel and copper. This matte is shipped to Great Britain and to the United States for refining. Nickel was recovered as a by-product in smelters at Deloro, Thorold and Welland, from the ores of the Cobalt district, these sources yielding 323,418 lb. of nickel oxide, 232,450 lb. of nickel sulphate, and 79,360 lb. metallic nickel. Cobalt also was produced at the same smelters. Among important non-metallic minerals produced in the Dominion we note asbestos, feldspar, fluorspar, gypsum and salt.

The interesting annual report of Arthur A. Cole, mining engineer for the Temiskaming and Northern Ontario Railway Commission, gives data on the mining industry in the Cobalt and Porcupine districts of northern Ontario. Gold production showed a steady increase over previous years, coming from the Porcupine, Kirkland Lake and Munroe districts. Silver production from the Cobalt district fell off nearly 3,000,000 oz., but showed an increase in value of over $1,000,000 due to the rise in the price of the metal.

A feature of the report relates to the use of flotation in Cobalt, showing the following plants and tonnages:

Mill	Tons daily
Beaver	30
Buffalo	600
Coniagas	200
Dominion Reduction	200
McKinley-Darragh	200
National (King Edward)	100
Nipissing	300
Northern Customs	200
Total capacity	1830

The use of the flotation process is making available for treatment current slime production as well as old tailing dumps, aggregating a quantity of about 2,500,000 tons. Assuming a recovery from the latter of 4 oz. silver per ton, a possible profit of $3,375,000 is shown.

Copper Output at Low Ebb

With the exception of several of the independent mining concerns, ore shipments from the Butte district are practically at a standstill in consequence of labor troubles. Production at the Anaconda mine in August was only 11,175,000 lb. of copper, as compared with 12,400,000 lb. in July and 28,800,000 lb. in August of last year. Labor troubles were responsible. Production for September will be very low indeed.

The Miami Copper Company reports an output of 160,000 lb. of copper in August, as compared with 4,498,595 lb. for the corresponding month last year. During July the mine was closed on account of labor troubles. Affairs at the Inspiration Copper Company's mine are much improved. Mining operations were resumed Aug. 24 and it is hoped that the output will be back at normal by the end of this month.

Minerals Separation vs. Butte & Superior

On August 25th Judge Bourquin, in the U. S. District Court, Butte, Mont., handed down his decision and opinion in the Minerals Separation et al. vs. Butte and Superior Mining Company.

The gist of the opinion is that the defendant having admittedly used the plaintiff's patented process in all of its elements until January 7th (the time of the Supreme Court decision), cannot now avoid infringement by adding, because of that decision, an excess of inert petroleum oils. Of this Judge Bourquin says:

> "The addition of the excess oil no more adds to or changes the process, no more avoids infringement, than would the addition of milk or other useless substance not a part of the process."

It is interesting to note that the operation upon which this infringement suit and opinion is based differs materially from the operations considered in the opinion of the U. S. Court of Appeals in the Miami case. Nor is this opinion, we would take it, of quite so wide an interest to the mining public, because of this fact that the Butte and Superior use the mechanical agitation process while in the Miami case a different and much more widely used form of flotation apparatus was involved.

In the Butte and Superior case the plaintiff's patented process in all of its elements was used, except that the quantity of the oil was brought without the claim of the patent, for the admitted purpose of escaping the patent, and, apparently, with poorer results. Whereas, in the Miami case a different procedure was used, but retaining the same amount of oil as the patent, getting a better and more economical result.

As to the Butte and Superior's increase of the oil to an amount without the claim of the patent, Judge Bourquin says:

> "The evidence likewise persuades. If the excess were effective and useful and not inert, useless and harmful, it would be without the claims of the patent, would be that of the patentees abandoned to the public, and no infringement."

In the Hyde case, the record of which was before the Supreme Court, and more particularly in the Miami case, in its argument before Judge Bradford, the plaintiff laid the greatest stress upon the reduction of oil; to such an extent indeed was this emphasized that Judge Bradford, in his opinion, stated that the reduction of oil, as compared with the prior art, is so great in itself as to constitute invention, and upon that ground sustained the validity of the patent.

Judge Bourquin says:

> "The tendency *was* [italics ours] to attach prime importance to reduction in amount of oil used, when in fact this is but a necessary incident (for which there are substitutes if not equivalents) to the creation of an infinitude of bubbles that do the work."

He then says that the patent clearly states the way to create this infinity of bubbles, and that they do the work. He says that the patent clearly points the skilled operator "the infinitude of bubbles and the degree of agitation and the amount of soap or oil to produce such bubbles."

In regard to the "critical proportions" of oil, as annunciated by the Supreme Court in its Hyde case decision, Judge Bourquin says:

> "There are 'critical proportions' of any oil used in this process, perhaps not a sharp divide, but rather a

broad one, for the amount of oil to produce sufficient and efficient bubbles must depend upon many other factors, viz.: the working cell space, amount of water, degree of agitation, kind and amount of ore, and perhaps on occasion, amount of metallic content, kind of oil, etc."

He also says:

"The patent describes oil 'considerably reduced' and refers to a 'fraction of one per cent' by way of example, and some claims limit oil to such a fraction, and a limited range within it, others are for a 'small quantity,' and for that reason held invalid by the Supreme Court. With later knowledge of this suit it is doubted that such would be the decision now. It is to be observed that limitation of the patent indicates that the Supreme Court believed the process might be operated with one per cent and more of oil, and contemplated that this would not defeat the patent, but might affect infringement."

As to the air Judge Bourquin says:

"At the same time, though heretofore somewhat ambiguous and obscure, present knowledge warrants the conclusion that the gist of this remarkable and valuable process and the actual discovery and invention are that whereas theretofore in ore concentration air had been used in desultory and fugitive bubbles as a makeshift incident of and supplement to oil and skin flotation, air can be made to do all the work by creating in water, or pulp, modified by a suitable oil contaminant an infinitude of bubbles.

"It is the first of its kind and the patent sufficiently discloses it and methods to those skilled in the art."

And further on he adds:

"How the air particles are introduced into the pulp is immaterial. For introduced they are still particles and not bubbles. It is this subsequent agitation within the claims of the patent which agitates 'the mixture until the oil coated mineral matter forms into a froth' or 'to form a froth.' And it is all one whether this be applied agitation or self-agitation, the agitation set up by the air particles themselves in merely rising through the mass and thereby coming in contact with both water and oil, all co-acting to form bubbles which capture the metal."

The foregoing paragraph is of interest because of its reference to the agitation in the process. The closing sentence of the paragraph especially so, in that it would appear to be opposed to the recent decision of the Court of Appeals in Philadelphia as to the degree of agitation necessary to bring it within the claims of the patent. The question of relative agitation, however, is not an element of the Butte and Superior case, since the agitation which was used is admittedly that of the patent.

As to the new evidence, over that of the Hyde case, Judge Bourquin says:

"The great mass of new evidence herein is but cumulative of the Hyde suit. The only new publication is the California Journal of Technology detailing a suggestive but rather misleading and abandoned experiment sufficiently referred to in the Miami suit."

The defendants had placed much dependence upon this publication in the California Journal of Technology because of its absolute description, as they consider it, of the "agitation froth," its method of production and characteristics, as antedating by some years the time of the invention of the patent.

As to the weight of new evidence necessary under the circumstances, the Supreme Court having declared the patent valid, Judge Bourquin says:

"If it be conceded that new evidence might warrant and demand that a trial court hold invalid a patent by the Supreme Court held valid, such evidence must be unequivocal, clear and convincing, in quality and quantity that inspires confidence and produces conviction that the patent is invalid beyond reasonable doubt. Not only does it fail here, but it strengthens the conviction that the patent is valid."

The decision contains some interesting figures as to metallurgical results obtained by the Butte and Superior when using the process, and treating some 1,598,000 tons of ore.

YEARLY AVERAGES

Year	Material Treated, Per Cent	Oil Used, Pounds	Concentrate Grade, Per Cent	Apparent Recoveries, Per Cent
1913.....	15.14	5.58	47.60	80.03
1914.....	14.14	2.22	53.03	86.08
1915.....	13.66	1.49	54.62	90.18
1916.....	12.89	1.43	53.83	92.63

"Progress is noted by leaner ores, less oil, higher grade concentrates, and greater recoveries, all coincident with advancing time,"

says Judge Bourquin. It is not clear just what the Judge intended to convey by that comment. Such improvement was undoubtedly due more to the metallurgical attention of the operators of the process than to any particular information contained in the patent itself. The sudden necessity in which they found themselves of disarranging all that they had been doing would also, naturally, account largely for the "poorer results" of the increased oil. But we are not sufficiently familiar with the evidence before the Court even to suggest this.

The Judge's comment as to the fact that had the larger amount of oil been more profitable they would undoubtedly have found it out prior to January 7 is certainly impressive, and it is natural that one would, upon the face of it, be unfavorably impressed by any simple evasion such as the opinion sets forth.

We must now await the decision of the Court of Appeals, which may, as they did before in the Hyde case, find more in the prior art, and greater weight in the new matter, than has Judge Bourquin in his opinion.

Fall Meeting of the Paper Industry

American and Canadian Technical Associations to Meet at Holyoke, Mass.

All arrangements have been completed by the local committee at Holyoke, Mass., for the joint convention there on Thursday, Friday and Saturday, Sept. 27-29, of the Technical Section of the Canadian Pulp and Paper Association and the Technical Association of the Pulp and Paper Industry.

The business meetings will take place in Knights of Columbus Hall, Holyoke, the opening sitting being scheduled to start promptly at 10 o'clock on Thursday morning, Sept. 27. The convention will be opened by President Henry P. Carruth with the introduction of Hon. John J. White, Mayor of Holyoke, who will deliver an address of welcome. The response for the association will be made by Martin L. Griffin, of the Oxford Paper Company. The selection of Mr. Griffin is especially appropriate, as he was one of the first chemists to be connected with a paper mill in the Holyoke district.

Among the papers to be presented at the afternoon session are the following:

1. "An Investigation of Stresses in Digester Shells," by Prof. H. O. Keay of the Laurentide Company, Grand' Mère, P. Q., Canada.

2. "Clay Retention: Influence of Clay Concentration,

Alum Concentration and of Alum and Size," by Prof. John D. Rue of the Fletcher Paper Company, Alpena, Mich.

3. "Some Observations on the Retention of China Clay by Paper Pulp," by Dr. Otto Kress and George C. McNaughton, of the Forest Products Laboratory, Madison, Wis.

4. "A Review of Different Processes for Causticizing Sodium Carbonate Liquors and the Separation of the Sludge," by Martin L. Griffin of the Oxford Paper Company, Rumford, Me.

The banquet will be held on Thursday evening at the Hotel Nanatuck.

Friday, Sept. 28, will be Visitation Day, an interesting program of visits to paper mills, papeterie plants and allied industries having been provided for members and guests.

The managers of the National Exposition of Chemical Industries have set apart Wednesday, Sept. 26, as "Paper Day" at the exposition in the Grand Central Palace, Lexington Avenue and Forty-fifth Street, New York City, and members of the Technical Association of the Pulp and Paper Industry and the Canadian Technical Section are invited to call and inspect the exhibits of apparatus, machinery and chemical products used in the manufacture of pulp and paper. A representative of the Technical Association will be in attendance at the association's booth to receive visitors and give any needed information.

Program of the Chemical Exposition

The following is the program of the third National Exposition of Chemical Industries, to be held during the week of Sept. 24, 1917, at the Grand Central Palace, New York. In addition to the addresses listed below, a very large number of attractive motion pictures will be presented, the program of these being shown on page 327 of this issue.

MONDAY, SEPT. 24

Afternoon—Opening addresses.

2:00 p. m.:

DR. C. H. HERTY, Chairman, Exposition Advisory Committee.

DR. JULIUS STIEGLITZ, President, American Chemical Society.

DR. C. G. FINK, President, American Electrochemical Society.

DR. G. W. THOMPSON, President, American Institute Chemical Engineers.

TUESDAY, SEPT. 25

Afternoon—Lecture.

4:00 p. m.:

DR. ALEXANDER SILVERMAN (University of Pittsburgh),

"Glass Manufacture." Illustrated specimens and stereopticon.

Evening—Addresses.

8:00 p. m.:

DR. M. T. BOGERT, Chairman, Chemical Committee National Research Council,

"The Operation and Work of the National Research Council for the National Weal."

DR. F. W. TAUSSIG, Chairman, U. S. Tariff Commission.

"The Tariff Commission and Its Operation."

DR. GRINNELL JONES, Chemist to U. S. Tariff Commission.

"The Tariff Commission and Its Operation with Reference to the Chemical Schedule."

WEDNESDAY, SEPT. 26

Afternoon—Meeting of the Technical Association Pulp and Paper Industry.

4:00 p. m.: Lecture:

M. A. WILLIAMSON (the Norton Co.).

"The Manufacture and Use of Alundum and Crystolon."

Evening—Addresses:

8: p. m.:

MR. W. S. KIES, Vice-president, National City Bank.

"The Development of Export Trade with South America."

MR. C. H. BOYNTON, President, American-Russian Chamber of Commerce.

"Russia and Its Relation to the United States."

DR. L. H. BAEKELAND, Member Naval Consulting Board.

"The Future of the American Chemical Industry."

THURSDAY, SEPT. 27

Afternoon—Symposium on National Resources for Chemical and Allied Industries:

2:00 p. m., speakers:

MR. C. H. CRAWFORD, Assistant to President, Nashville, Chattanooga & St. Louis Ry.

"Ahoppa Awan Tewa."

MR. V. V. KELSEY, Chemist-Industrial Agent, Carolina, Clinchfield & Ohio. Ry.

"Building a Complete Cycle of Chemical Industries on the Clinchfield."

DR. T. P. MAYNARD, Mineralogist-Geologist, Central of Georgia Railway.

"Industrial Interpretation of the Mineral Resources Along the Central of Georgia Ry."

DR. E. A. SCHUBART, Mineralogist-Geologist Norfolk & Western Railway.

"The Development of Chemical Industries Along the Norfolk & Western."

DR. J. H. WATKINS, Geologist, Southern Railway.

"Railroad Industrial Preparedness."

Evening—Meeting: The American Institute of Chemical Engineers.

8:00 p. m.: Joint meeting: The New York Sections, American Electrochemical Society, The American Institute of Mining Engineers.

FRIDAY, SEPT. 28

Afternoon:

3:30 p. m.: Meeting—American Ceramic Society.

DR. MALINOVSZKY.

"Refractory and Stoneware of Malinite."

Evening—Meeting:

8.00 p. m.: New York Section, American Chemical Society.

The Engineering Council

Its Organization, Aims and Sub-Committees

The formation of an Engineering Council is the outgrowth of a real need for proper consideration of questions of general interest to engineers and to the public, and to provide the means for united action upon questions of common concern. Many such questions have come up in the past and will arise in greater number in the future. This war has brought out very impressively the actual need for united action of some kind. At present the Council is concerned only with four societies, because that seemed the most practical way of getting a group of men together to answer the immediate needs, but these societies do not assume to speak for all engineering societies in the country. Criticism that they are exclusive in any way is utterly mistaken. There is the hope that such a Council, by proving itself effective, may lead to much wider cooperation in a strictly representative body for all engineers, and thus pave the way for a very much larger union in the future.

How can the Council be enlarged? By a union of all societies, either as the outgrowth of the present Council or by a congress of engineers leading to united action by all societies. The first method will be the most natural one, because many local societies and national societies also have a large membership in the four societies at present concerned. We have three classes of engineers to reach: first, those who are members of local societies and not members of national societies; second, those who are members of national societies and not members of local societies; and third, those who are members of no society. The last named class constitutes a very large number in our profession. We are almost as mixed as American citizenship, and we suffer therefrom just as much as America with a population representing every race and every people in Europe. There can be no question of the enormous advantage of union. That union should be completed by strengthening the existing agencies and not by the formation of new societies. The national societies are thoroughly national notwithstanding an occasional complaint that they are run by New York. If they have not been able to express the democratic spirit of our country as fully as might be desired it is the fault of the members in all the states and not of the city in which the principal offices are located.

The four societies concerned at present are the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. They have come together in pairs from time to time in the past for special purposes, and there have been general conferences on subjects requiring immediate settlement, but until the Council was definitely organized in June there was no permanent body to advise all the societies. We have had many fruitful discussions in the past leading to useful action. The Standardization Committee which has been organized to represent five societies has passed upon commercial standards of all kinds. This committee has great possibilities and it should be enlarged enough so that its influence may become very widespread.

Many problems have already been presented before the Council. Its personnel made up of twenty-four men representing equally the four societies is well balanced and judicial. The first duty was necessarily the organization and appointment of standing committees, which have already been reported in the press. They might with advantage be mentioned here:

1. Committee on Public Affairs, comprising Messrs. C. W. Baker, G. F. Swain, S. J. Jennings and E. W. Rice.

2. Committee on Rules, comprising Messrs. J. P. Channing, Clemens Herschel, N. A. Carle and D. S. Jacobus.

3. Committee on Finance, comprising Messrs. B. B. Thayer, I. E. Moultrop, Calvert Townley and Alex. C. Humphreys.

Certain questions relate, however, to the war and the assistance that engineers can render. A committee to be called the American Engineering Service Committee was appointed with instructions to invite the cooperation of all engineering societies. This committee in the first instance consists of A. D. Flinn of the Civil Engineers, A. S. McAllister of the Electrical Engineers, George J. Foran of the Mechanical Engineers, G. C. Stone of the Mining Engineers and E. B. Sturgis of the Mining and Metallurgical Engineers. Its present duty is the tabulation and listing of the members of the five societies represented, in order that we as a profession may be in a position to take a larger part in the industries after peace is declared. This tabulation has already in part been done, but in a rather unsystematic and unequal way. It is hoped that the new committee by having additions from other societies may make a final and lasting tabulation of all the engineers in the United States. The list is to be kept in the Engineering Building for general use in Government problems and in the industries. At present the committee is devoting its attention to the immediate need of the hour, namely, the procurement of men for special service in the Government. A list of specialists in the societies has already been completed. There are three methods by which engineers may enter United States service: first, through some organization; second, through individual application to a department of the Government; and third, through selection by the Conscription Law. But this is war service wholly and not civil service, which is the same now as it has always been. As a matter of fact, a great many engineers have already entered through the engineering societies, through colleges and through various special boards in Washington. The importance, however, of a complete list of engineers and their professional specialties cannot be over-rated. Such a complete list can be made only with the help of the local as well as of the national societies. The committee mentioned above is organized with George J. Foran as chairman and A. S. McAllister as secretary. All societies should respond to the request for co-operation.

Another committee, of which Harold W. Buck is chairman, is called the War Committee of Technical Societies. The members are Messrs. H. W. Buck, A. M. Greene, R. N. Inglis, C. R. Corning, G. C. Stone, D. W. Brunton, J. M. Boyle, J. V. Davies, Joseph Bijur, A. S. McAllister, W. D. Richardson and Charles Baskerville. It was appointed to assist any organization in Washington, such as, for instance, the Council of National Defense, the National Research Council and the Naval

Consulting Board, in any way in which it can bring to the attention of the engineers of the country the necessity for thought and help in the numerous problems that arise.

A council organized by the enlargement of the present Engineering Council can be very effective in many ways without interfering with the autonomy of any individual society. Every society has some definite purpose of its own, and also some which it holds in common with all other societies. One of the latter purposes relates to public service and to co-operation. To the end that all societies may understand fully their opportunity, the committee of which Mr. Foran is chairman has made a complete list of all the societies and their officers, and communications will be sent out inviting co-operation, and it is hoped that the Council may be successful in arousing sufficient interest to bring about a larger and better Council for all engineers.

In organizing the Council provision was made for the election to membership of other national engineering and technical societies. There is no doubt that rules can be made under which these societies may become members. This will involve consultation and discussion in the future.

The office of the Council will be in the Engineering Building, 29 West Thirty-ninth Street, New York City.

(Signed) IRA N. HOLLIS, Chairman,
Worcester Polytechnic Institute, Worcester, Mass.
CALVERT TOWNLEY, Secretary,
115 Broadway, New York City.

MEMBERS OF THE ENGINEERING COUNCIL

United Engineering Society—Clemens Herschel, B. B. Thayer, I. E. Moultrop, Calvert Townley, secretary.

American Society of Civil Engineers—John F. Stevens, George F. Swain, vice-chairman, Fred H. Newell, Alex. C. Humphreys, John D. Galloway.

American Institute of Mining Engineers—P. N. Moore, S. J. Jennings, B. B. Lawrence, J. Park Channing, Edwin Ludlow.

American Society of Mechanical Engineers—Dr. Ira N. Hollis, chairman, John H. Barr, Charles Whiting Baker, Arthur M. Greene, Jr., Dr. D. S. Jacobus.

American Institute of Electrical Engineers—H. W. Buck, vice-chairman, E. W. Rice, N. A. Carle, P. Junkersfeld, C. E. Skinner.

Record Production of Fluorspar in 1916.—American mines broke another record last year in the production of fluorspar, as shown by statistics compiled under the direction of Ernest F. Burchard, of the United States Geological Survey, Department of the Interior. In 1916 the shipments were 155,735 short tons, valued at $922,654, an increase of 14 per cent in quantity and of 21 per cent in value over the shipments of 1915, heretofore the record year.

The increased demand for fluorspar has come largely from the manufacturers of open-hearth steel, who use the mineral as a flux, but the demand for it in other metallurgic operations and for the manufacture of hydrofluoric acid has been very active. One of the newer uses for fluorspar is as a reagent in the recovery of potash from feldspar and from Portland cement clinker.

Russian Engineers in the United States

Having in view the coming development of the natural resources of Russia in the very near future, the Russian Provisional Government has sent a special delegation to the United States, entrusting it with the task of investigating the conditions existing in the mining and metallurgical industries of this country, as well as the laws relating to the discovery, ownership and development of mineral resources. The commission is headed by Mr. Fedor M. Foss, member of the Bakhmeteff Mission as the representative of the Ministry of Commerce and Industry. Mr. Foss is a mining engineer and director of several mining and metallurgical works in the Ural Mountains, notably Count P. P. Schouvaloff's Lyssvensky properties, producing charcoal iron, tin plates and platinum, and the Upper Issetssky works, producing iron and copper. Mr. Foss has as associates on the commission the eminent geologist Ivan M. Goubkin, who is a specialist in petroleum, and another member of the geological committee, A. A. Snietkoff, a specialist in questions pertaining to coal. Alexander Stepanoff is secretary.

The commission has entered the United States as the leading nation in their development of national resources. They feel that the most modern and economical developments of mining and metallurgy can be found here. Also in such matters as geological surveying, investigation and land classification the United States stands pre-eminent. The Provisional Russian Government therefore felt that it would be most suitable to study all these questions in the United States.

The commission has already been in Washington, where the Geological Survey and Bureau of Mines have opened their records for examination, and have aided the members in every possible way, planning an itinerary covering the entire country, so that Messrs. Foss, Goubkin and Snietkoff can see the work on the spot.

The commission intends to stay not less than four or five months, during a large part of which time the individual members will visit various localities of most interest to them. In the near future they plan upon inspecting the steel works of the Pittsburgh district, the anthracite fields of Pennsylvania and the Michigan copper country. Following the St. Louis meeting of the Institute of Mining Engineers, they intend visiting the oil wells in Oklahoma and the mining and metallurgical centers of the Mississippi Valley and the Rocky Mountains.

Upon returning to Russia, Mr. Foss will present a report to his government, reciting his findings as to the applicability of American methods to Russian problems. While it is yet early in his investigations, Mr. Foss feels at present that it would be of very great advantage to his country if American capital, engineers and plants could be bodily transplanted to Russia by the granting of the necessary concessions. These plants, operating on the most modern ideas, would then be accessible places in which to school Russian engineers, who in turn would spread over their entire country, building new works and developing new processes from this foundation.

The mining, metallurgical and chemical engineers of the United States gladly welcome these brother engineers, and will be more than happy if our work and ideas may be of help to them.

Sixth Annual Safety Congress

The sixth annual safety congress of the National Safety Council was held at the Hotel Astor, New York City, on September 10th to 14th, inclusive. One of the special features of the congress was an exhibition of devices and appliances pertaining to accident and fire prevention, and sanitation, held during the same week at the Grand Central Palace. This was the largest and most complete safety exposition ever held, and was the center of interest of a large attendance of engineers and managers interested in safety work.

Several general sessions of the entire membership were held thru the week, when topics of general interest were discussed by leading personages, such as **Hon. William B. Wilson,** Secretary of Labor; **Dr. Charles P. Steinmetz, Miss Ida M. Tarbell,** and **Dr. Adrian V. S. Lambert,** of the Rockefeller Institute. An imposing list of papers on various phases of human conservation was presented in various sectional meetings, subdividing the membership into the following distinct groups:—Public Safety Division, Public Administrative or Governmental Division, Health Service and Industrial Relations Division, Transportation and Public Service Division, and the Industrial Division. The Transportation Division was subdivided into four sub-sections, viz.: Electric and Street Railways, Marine and Navigation, Public Utilities, and Steam Railroads. The Industrial Division is formed by the following sub-sections:—Chemical and Rubber; Logging, Lumbering and Woodworking; Metals and Metallurgy, including Foundries, Iron and Steel Works; Mining and Quarrying; Automobile Manufacturing; Car Builders; Paper and Pulp; and the Textile Trades. The scope of the activities of the National Safety Council, and the wide influence of this convention can be appreciated after a mere statement of these separate meetings held during this busy week.

The Chemical Section met on Wednesday, Sept. 12th, under the chairman, **Mr. J. R. de la Torre Bueno,** of the General Chemical Company. **Dr. John S. Bates,** of the Imperial Munitions Board of Canada, gave a most interesting talk on "Manhood Conservation in Munitions and Chemical Plants in Canada." **Mr. R. G. Griswold,** of the E. I. Du Pont De Nemours Co., then addressed the section on "General Dangers from Strong and Mixed Acids, from the Safety Man's Point of View." Mr. Griswold pointed out that the average workman has no appreciation of the serious results that may arise from contact with strong acids. Pipe fitters, for instance, become exceedingly careless and neglect the essential precaution of first making sure the line under repair is thoroughly drained. Even then it should be insisted that he cover his skin with vaseline, and use goggles, rubber mask and gauntlets, in order to make sure of protection against drip and spirits. Showers, sprinklers or water buckets should be at every hand to deluge any man burned with acid. Nitric acid and fuming sulphuric acid fumes have a caustic effect upon the mucous lining of the respiratory organs, and men in contact with them should be required to wear a first class respirator fitted with an appropriate absorbent filter.

Mr. E. Fiesinger, of the Semet-Solvay Co., discussing "The Hazards of Caustic Soda Manufacture and Use," said that the solid caustic soda and liquor of more than moderate strength, especially if hot, attack the clothing and quickly burn the flesh. Goggles, rubber puttees, rubber or canvas-covered leather shoes on wooden clogs should be insisted upon. The best antidote for a caustic burn is a 2% acetic acid solution, which should be kept in cabinets on each building column, together with a supply of carron oil, which should follow the acetic acid in severe burns. Carron oil is a mixture in equal volumes of filtered lime water and raw linseed oil. *No absorbent cotton* should be used in cleansing these burns.

Dr. R. W. Chaffee, Staff Physician of the Solvay Company, read a short paper on the "Prevention and Treatment of Cases of Poisoning by Tri-Nitro Toluol and Picric Acid." Dr. Chaffee recommended a strict physical examination of all applicants for work in such plants, and a course of instruction in the nature and danger of his work. A complete change of clothing on coming to work and absolute cleanliness is prerequisite to the maintenance of health. Rubber boots, coats and gloves should be furnished. Thorough plant ventilation is essential. At the first symptom of TNT poisoning the employee should be put into light outdoor work on garden or farm under careful supervision and medical treatment, which must continue some time after recovery to prevent a relapse. Fumes should be combatted by ventilation, good retort construction and respirators. Several thicknesses of fresh cheese cloth saturated with sodium bicarbonate is an excellent respirator. The "itch" which follows contact with picric acid is speedily removed by a few days' change of work.

A paper on "Packing and Plant Handling of Hazardous Chemicals, with Special Reference to Returned Empties," was read by **N. A. Laury,** of the General Chemical Co. Mr. Laury thought that the best general package for acid is the standard wood-packed glass carboy, if made of approved materials. Mechanical handling is much to be preferred; two sticks under the side cleats handled by two men is cheaper and much safer than direct handling. Roller skids should be used in most cases. The safest practicable stopper is a ground glass or stoneware plate held on a tar paper, asbestos or rubber gasket, by a wire clip like a fruit jar. The greatest danger to carboys is the weakening of the wooden case by acid, but this can be eliminated by a wood preservative called "Preservol." The author concluded with remarks on the safe handling of hydrofluoric acid.

The metallurgical sections of the council held no less than four meetings, at which some very interesting papers were read, which we hope to publish in full in a later issue. At the Thursday session (Sept. 13) **Mr. Frank E. Norris,** of the American Rolling Mill Co., discussed "Safe Practices in Sheet Mills." Mr. Norris pointed out that the sheet mill of fifty years ago was quite similar to the modern mill. The risks are chiefly in handling the raw material and the slippery, sharp-edged sheets. The transportation of packs of sheared sheets entails a big risk, no practical device for this service has yet been made absolutely safe. A large percentage of cuts come in handling sheets to the leveler rolls, which may largely be avoided by sheepskin gauntlets, wool outside. A light mask for workers around spelter pots has saved many splash burns. Twenty-six per cent. of all accidents happen to new men.

Boston Meeting of American Chemical Society

Important Discussions on Chemists and Chemistry in Warfare

The meeting of the American Chemical Society, held in Cambridge and Boston, Sept. 10-13, inclusive, was characterized by a great seriousness of purpose and a splendid spirit of service to the country. What the chemists are doing and will do will perhaps not be publicly recognized for a long time, but when the story is written, the immense value of the chemists' work will perhaps be better realized. A great many things that the chemists are doing were brought out at the meeting, which was the second that the society has held since the war started. The meetings, which were very well attended, were held in the new buildings of the Massachusetts Institute of Technology in Cambridge.

Tuesday Sessions

In welcoming the society to Cambridge on behalf of the Northeastern Section, **Dr. H. P. Talbot**, head of the Department of Chemistry of the Massachusetts Institute of Technology, urged everyone to give serious attention to the problems of the war. He said there was no body of men similarly situated which was capable of contributing so much as the chemists. The doctrine of economy must be preached and practised and a large supply of well trained men must be furnished to help win the war.

In his response, **Dr. Julius Stieglitz**, president of the society, said the meeting was called primarily to discuss war problems. He said the officers of the society had done considerable work in connection with the resolutions adopted at the Kansas City meeting to exempt chemists from the draft and keep them in chemical work. The burden of this work was done by Drs. Parsons, Nichols and Bogert. Dr. Stieglitz said he could foresee the time when there would be a decided shortage of chemists.

The only matter of business taken up was the election of Professor **Victor Grignard**, of the Faculty of Sciences of the University of Nancy, to honorary membership in the society. Professor Grignard is in this country as a member of a French commission and was present at the meeting. He expressed his appreciation of the honor in a short speech.

AMERICAN MADE OPTICAL GLASS

Arthur L. Day, director of the Geophysical Laboratory in Washington, gave a splendid address in which he outlined the difficulties encountered in the initiation of optical glass manufacture in America. This country had depended on Germany and France for its optical glass, the prisms, heavy lenses, etc., never having been made in this country. Last April, when we entered the war, our stocks were about used up, and none was available from France or England, as all their surplus was badly needed by their governments.

The details of the manufacture could not be obtained from England or France, as the processes were secret and not known to those governments. The Bureau of Standards and the Bausch & Lomb Co. had made a few experiments leading to the synthesis of these glasses, which was the extent of American efforts up to April. At that time a conference was held in Washington and the Geophysical Laboratory was asked to devote its time to this work.

The problem was to make out of American raw materials a tolerable glass and make it quick. On investigation it was found that there was but scanty published information on the relation between the ingredients and the refractive index of the glass. Only about one-third of the last thirty years of its development is recorded in the literature.

After careful figuring by the army and navy officials it was decided that six was the minimum number of different kinds of necessary glasses. The problem was accordingly taken up with the manufacturers, who had suitable furnaces, and a tolerable glass has been produced, but much further improvement is however needed.

Mr. Day expressed most cordial appreciation of the assistance given in the work by the Bausch & Lomb Company. The difficulties in producing the glass were first: that not enough was known of the relation between the ingredients and the optical products, as has been mentioned before. A great deal of information has now been collected on this angle of the situation. Secondly, the possible American raw materials are not well known, nor thoroughly available, and not entirely pure. For instance, iron affects the transparency of the glass and the ingredients must be iron free.

The glass making pots must not be corroded too much since American clays contain 2.5 per cent iron, as compared with 1.5 per cent. in the French clays. The importance of this is obvious when it is realized that not more than 0.02 per cent. iron should be present in the resulting glass.

A further difficulty was in securing pure potash. This requirement has been practically met by the Armour Fertilizer Works, which has recently produced a pure potash, free of sulphur and chlorine.

Mr. Day concluded by saying that in October 45,000 lbs. of optical glass would be turned out in Rochester, and that if the raw material could be obtained in a pure enough condition, a glass equal to any glass used in Europe could be made with the knowledge obtained since April.

CONFERENCE ON CHEMISTS AND CHEMISTRY IN WARFARE

The conference on Tuesday afternoon was the most interesting feature of the meeting. The society was fortunate in having present Dr. Wm. H. Nichols, Chairman of the Committee on Chemicals of the Council of National Defense, and Dr. M. T. Bogert, Chairman of the Chemistry Committee of the National Research Council. Dr. Nichols' address is abstracted very fully on the following page.

Work of the Committee on Chemicals

BY WM. H. NICHOLS

It cannot be impressed too frequently or too strongly on the minds of the American people that the war on which we have entered is one which will require the faithful services and intelligent co-operation of every loyal citizen of the Republic, male and female, until the very end. No half-way measures will suffice. We are pitted against a power which has been preparing for many years and which did not strike until its preparations were complete. With that thoroughness for which the German people are deservedly noted, assisted and guided at every step by a highly intelligent Government, which, for many years, knew what it was aiming to accomplish, and intended to be ready for any eventuality, there was probably nothing which could be foreseen by human intelligence which was not provided for when the Belgian frontier was crossed. While this was true in all fields it was particularly true in the field of chemistry, which has proved to be in many ways the most important science made use of in the titanic struggle. Many of those present will remember the striking lecture of Dr. Bernthsen, delivered during the Eighth International Congress of Applied Chemistry to an audience which packed the hall in its eagerness to learn the last, and to many the first words on the fixation of atmospheric nitrogen. Probably no one among them realized the enormous influence which the process described was so soon to have on the fate of the world. We had been accustomed to consider that nitrogen fixation was practically dependent upon the electric arc and involved the consumption of enormous electrical energy. Dr. Bernthsen's exposition of what is known as the "Haber Process" was so clear and so skillful that even those who gave it only a passing thought could see the great potentialities of employing hydrogen instead of oxygen in the fixation process. Since the date of the delivery of that lecture in 1912 the production in Germany of nitric acid and ammonia in its several forms has become colossal and it may be safe to say that without the process alluded to the war from the German side would long ago have languished from scarcity of explosives, and the fields have become barren from lack of nitrogen. It is conceivably not too much to infer that the war was not launched until the way was clear for the production of nitrogen compounds after the vast accumulated stores of Chilean nitrate had become exhausted. This is one instance of many which might be cited to show the extreme preparedness of the German nation. From my own knowledge I can say that, by comparison, the English and French were unprepared, both in men and equipment and this was thoroughly understood by their enemies. As for Russian preparation, it was carefully looked after in Berlin.

While the beginning of the war found England and France not only unprepared but almost stunned by the suddenness of the shock, they lost no time in getting under way. At first many mistakes were made, and many steps taken which had to be retraced, but fortunately no vital errors were committed. As a result of the gigantic program laid down, covering every phase of preparedness, these countries found themselves able to supply the vast armies which they organized with every article, to the last detail, needed to make them effective. This offers one of the most extraordinary examples of intelligent co-operation which the world has ever seen. It is little short of a miracle.

Promptly after the declaration of war our authorities at Washington proceeded to take steps with commendable rapidity. They have been criticized a great deal because these steps have not been more rapid, but those who are acquainted with the difficulties of the situation realize that this criticism is not merited. We are a peace-loving people and had been at peace many years. Ours is a democratic government and no one man or group of men has had such powers as will be found to be necessary before we can hope to effect an organization able to cope with the demands that will be made upon it. Our organization at present is, in my opinion, temporary. Of course, the President is and must be its head. Next to him is the Council of National Defense composed of six members of the Cabinet. After this Council comes the Advisory Commission of the Council of National Defense and the War Industries Board, whose duties are not yet clearly defined. The Advisory Commission is divided up into several committees, among them one on Raw Materials. The Committee on Chemicals is one of the sub-divisions of this, and its functions are advisory. Why one of the most abstruse of all the sciences having to do with some of the most delicate and highly refined finished products should come under the head of raw materials is hard to see, but such is the case. We chemists are accustomed to be misunderstood.

I was honored with the chairmanship of this committee and have organized it along lines which previous experience led me to believe would be efficient. The work has been divided into the following heads:

Acids, Fertilizers, Alkalies, Electrochemicals, Coal Tar By-Products, including Ammonia, Pyrites, Miscellaneous Chemicals and Phosphate Rock.

I was able to secure the service of men well known to the industry as chairmen of these sub-divisions and they in turn were fortunate in obtaining many of the best men in the industry for their special committee members. In all, the Chemical Committee with its subcommittees includes some thirty-seven men. These chairmen meet twice a month in Washington and in the interval are at work endeavoring to solve the problems of production which are assigned to them. I think you understand all the work of the Committee on Chemicals has to do with the actual materials, not with research. This latter subject is in charge of the National Research Council, the chairman of whose chemical committee is a member ex-officio of the Committee on Chemicals, thus keeping both branches in close and constant touch. The Bureau of Mines is represented by its able director.

The committee is located in inadequate offices in the Interior Building, fortunately adjoining the office of the honored secretary of this society whose services are thus easily and quickly obtained at any time. Our duties are many, some merely routine, such as obtaining information for various departments, procuring satisfactory prices for articles needed, keeping in touch with the railway commission to see that goods move as freely as possible, and many other of a like character which will occur to you. In addition to these there are many duties of a more serious character requiring much active and intelligent work. Generally speaking, the manufacturers have responded admirably and there are

many instances of sacrifices being made for which recognition is not expected and probably will not be received. It would be idle to state that there are no exceptions, but every effort is being made to produce satisfactory results without resort to higher authority. We feel confident that as the war progresses the ability of the committee will be found to be equal to the problems as they arise. If, however, it should be found that they are not we understand perfectly that we will be expected to make room for those who are better qualified. The main point is that our army and navy must be supplied with everything that the chemist can give, while at the same time our industries shall be interfered with as little as necessary. It may happen as time passes that in spite of all precaution the industries may suffer to some extent, but you can depend upon it that this will not be the case if it can be avoided by human foresight. There must come a time when this war shall end and we should be constantly preparing ourselves not only to provide its requirements while it lasts, but to meet conditions as we find them at its termination. Many theories have been advanced as to what will happen when peace once more blesses our staggering world, but I believe we should so plan our affairs that whether expansion or contraction results, we will be able to meet either conditions with a bold front.

One of our most serious difficulties arises from the unwillingness of the military authorities to recognize the wisdom of exempting chemists as a class from the draft. Almost from the beginning of our work we took up this question from various angles, realizing as we do the vital importance of keeping chemists at work in their profession not only at the present time but more particularly for the future. Our civil, mechanical, electrical, and other engineers can be made good use of at the front and not only contribute greatly to the success of our forces, but by the valuable experience obtained in their profession can improve themselves for future service at home. This is not true of chemists, with an exception here and there. Once in the army and at the front, if he be only recently out of college he is lost to chemistry forever. They are not slackers and are just as anxious as any other red-blooded young men to get into the fray, and therefore I have believed it wise not only to have them exempted from the draft, but declined in case they should enlist. Already serious trouble has come to many of our chemical plants and plants employing chemists, as a result of the draft, and unless wise provision be soon made we can foresee a condition which it will cost months to rectify. Why should we not take the advantage of the experience of our English friends who have passed through this same situation and learned that there is a large class of men who can do more valuable work behind the lines than they can in the trenches?

The one great need of any colossal organization is the complete co-ordination of all its parts. No one can claim that the organization in Washington has yet reached this stage or even approximated it. Many things are done several times over and many others needed are not done at all. I presume this condition is unavoidable at this stage of our progress but it must not be allowed to continue indefinitely. We have the utmost confidence that the President and his advisors can be relied upon to produce the required organization co-ordinated and articulated so perfectly that it will work with giant force and with little friction. This will come after politics have given place to patriotism and this will happen, I believe, when the people of the country thoroughly appreciate the fact that we are at war. In any event, I am sure the country can rely upon the 10,000 chemists of this society to do everything that lies in their power to see that the chemistry branch, possibly the most important of all, is not found lacking in either ability or patriotism.

Dr. M. T. Bogert then presented an address on the work of the Chemistry Committee of the National Research Council, reviewing their activities in the mobilization of research chemists and coördination of their investigations, both of this country and of our allies. He also mentioned their efforts in the production of cheap and portable hydrogen plants for the aviation corps, and in the absorption of hydrogen gas in the submarine battery rooms, and related U-boat problems. The most important fields of their work is in the production of poisonous gas, gas masks, gas shells, and so on. We hope to publish this address in full in our succeeding issue.

Following Dr. Bogert's address, **Dr. Roger Adams,** of the University of Illinois, told of the work which was being done there in making some of the rarer organic chemicals, badly needed by laboratories for analytical and research work. About ten men are employed and about 80 different products have been made in one- and two-pound lots.

Dr. Stieglitz then called on **Dr. Angell,** another member of the French commission, who gave an interesting talk (in English). He said it was a very great mistake to allow the chemists to go into the trenches, as was done in France, where 60 per cent. of the young chemists had been lost. It took a long time to have scientific men recognized as of value by the military authorities. The reason for this was that the officials did not know where they were needed. At the present time, however, France's laboratory and chemical manufacturing system is very well organized for war work, the government controlling practically all the explosives' manufacture. Dr. Angell said his commission had come to the United States to acquaint American chemists with what France had done in order to avoid duplication of effort and to cooperate in any way possible.

Dr. A. A. Noyes, a member of the committee appointed to investigate the nitrate situation, then told of the recommendations of the committee, which matters are discussed fully on pages 255 and 261 of this issue. He said the conversion of NH_3 into HNO_3 worked out by co-operation with the Semet-Solvay, General Chemical and Cyanamid Companies, gave an efficiency of 90 per cent., and was very satisfactory. He said no large scale attempts had yet been made to convert cyanide into ammonia by steam in the Bucher process.

Wednesday Sessions

On Wednesday and Thursday divisional meetings were held by the fertilizer, rubber, pharmaceutical, industrial, biological, physical, inorganic and organic sections. Of especial interest was the conference held by the Industrial Division, Wednesday morning, on "The Industrial Chemist in War Time."

The sessions were presided over by H. E. HOWE of Arthur D. Little, Inc., Boston, chairman of the division.

The whole time Wednesday morning was given over to a series of talks on the part of industrial chemistry in the war.

Dr. W. H. Walker head of the chemical engineering department at M. I. T., said there was a shortage of industrial chemists and that more men must be brought into chemical engineering. He said it was more difficult to start a man in chemistry than in other branches, owing to the difficulty of translating it into every-day experiences. The course is also more expensive and this is often a deciding factor. Institutions should have loan funds to help needy men, and the men should be shown more clearly the opportunities existing in the chemical engineering field.

Dr. Hildebrand of the Bureau of Standards, Washington, D. C., described the work which was being done there in the new chemical building, on war problems.

Dr. L. H. Baekeland, member of the Naval Consulting Board gave a very interesting talk on the work of the Board. The Naval Consulting Board was created to pass on inventions for the Navy. It now, however, also passes on them for the Army. The overwhelming majority of the suggested ideas are not worth much, and it has been necessary to issue a pamphlet telling the people what not to do. In suggesting new articles to be used, the questions of their economical manufacture and availability of raw materials are not considered. He said *new* explosives is not what is wanted but a good supply of what those we already know about. The experience which England had with cordite is illustrative. This explosive needs acetone which is a scarce article today in England. It would have been better to adopt an explosive needing ether, as its manufacture is easier.

Dr. Charles L. Parsons told of some of the activities of the Bureau of Mines, which has been devoting its attention to such problems as the supply of pyrite and elemental sulphur, the manganese supply, use of low grade ferromanganese, electric furnace for melting of brass, special steels, concentration of molybdenum ores, quicksilver production from low-grade ores, apparatus for oxidation of ammonia to nitric acid, production of mesothorium from monazite, and gas warfare.

Others who spoke at the conference were Dr. Charles H. Herty, who made a plea for greater publicity of chemistry, and Prof. A. H. White of the University of Michigan, who is a captain in the Ordnance Department, who said he had been most pleasantly surprised by the treatment of civilians who entered the war department. Charles F. Quaintance, secretary of the company manufacturing Coors porcelain, made a plea for a continuance of the support of American chemists of our domestic porcelain manufacturers. He said that foreign products should not be allowed to destroy our industry. Dr. Bigelow of the National Canners' Laboratory gave an interesting talk on the food situation. Professor Olney of the Lowell Textile School and Dr. Hawley of the University of Wisconsin also spoke.

INDUSTRIAL DIVISION

The regular meetings of the Industrial Division started on Wednesday afternoon. Officers elected for the next year were W. H. Walker, chairman, S. H. Salisbury, Jr., secretary. At the Wednesday afternoon session two papers were presented by Gustav Egloff, who was, however, personally unable to read them as he was called West unexpectedly. Both the papers were short, the first describing the cracking of solvent naphtha in the presence of Blau gas.

The second dealt with the "effect of pressure on the formation of benzene and toluene from gas oil."

Gas oil derived from a Pennsylvania crude petroleum was subjected to pressures of one, eleven and eighteen atmospheres at constant temperature of 700 deg. C. to form benzene and toluene.

The following table tabulates the analytical data:

700 Deg. C.			
Atmospheres pressure	One	Eleven	Eighteen
Specific gravity recovered oil	0.891	0.976	0.998
Per cent of recovered oil	13.3	25.0	18.0
Per cent benzene in recovered oil	11.3	22.3	22.4
Per cent of toluene in recovered oil	7.5	15.1	12.9
Per cent of benzene on basis oil used for production	1.5	5.6	4.1
Per cent of toluene on basis of oil used for production	1.0	3.8	2.3

A paper on "Scrubbing Carburetted Water Gas" was presented by Robert J. Moore and Gustav Egloff. This will be found elsewhere in this issue.

"The Deposition of Silver Films on Glass" was the subject of a paper by A. Silverman and R. M. Howe.

"Chars and other Decolorizing Agents" was the subject of a paper by Charles E. Coates. Dr. Coates found that by heating almost any form of carbon at a certain temperature in an electric furnace its decolorizing power was greatly increased in acid sugar solutions, and that a good decolorizing agent could be made from pine wood. He thought the decolorizing power of carbon was a function of the porosity and that this porosity was changed by heating.

Two papers, one on porcelain ware tests and on on glassware tests were read by C. E. Waters. The authors of the latter paper were Percy H. Walker and F. W. Smither.

"Potash Recovery from Greensand" was described by H. W. Charlton. He showed samples of good quality brick made as a by-product from the manufacture of potash from greensand. He said greensand was a cheaper raw material than feldspar as it required no quarrying. The greensand is digested with lime and the solution filtered and evaporated. In order to produce 1 ton of K_2O per day about 30,000 bricks would have to be made but all kinds of tile and other materials can also be made. Mr. Charlton said the process would pay on a pre-war basis.

Julius Stieglitz in his presidential address delivered Wednesday evening said that chemistry is all that has saved Germany. He urged a high tariff on dyes and drugs, and said that manufacturers should share more profits with chemists.

Thursday's Session

At the Metallurgical Symposium Thursday morning, Dr. W. A. Whitaker, of the University of Kansas, Lawrence, presided. H. M. Boylston presented a paper on "Problems in the Metallography of Steel." Elwood Haynes presented a paper on "Stellite as a Substitute for Platinum." He said that it has the same melting point and is not attacked by nitric acid, that it can be used in the arts. I. P. Parkhurst presented a paper on "Effect of Annealing Steel on Its Electrical Resistance." E. R. Weidlein presented a paper on "Sulphur Dioxide in Hydrometallurgy." E. P. Mathewson presented a paper on "Importance of Flotation;" Dr. W. D. Bancroft, a paper on "The Theory of Froth;" O. C. Ralston, one on "Chemicals Used in Flotation," and Dr. W. A. Whitaker, one on "Flotation of Zinc Tailings."

Rubber and the War

By Andrew H. King

If anything, rubber plays a more important part in the carrying on of modern warfare than it does in time of peace. War separates essentials from non-essentials, and in this way impresses upon our minds the importance of many commonplace things. Rubber is one of these. As a basic raw material it ranks next to iron. There is nothing else like it. It fills a place absolutely its own. It has no rivals. The combinations of strength, elasticity, and mobility in such wide variations are not to be found elsewhere in nature. It is firmly interwoven in our fabric of civilization.

Its influence has for the most part been constructive rather than destructive. Whether it be found in the hose of a city fire department or in the soldier's gas mask, it is a singular fact that its purpose seems to be the conservation of human life and comfort. War is the most destructive of the games humans play at. The labor of centuries is destroyed in a brief five minutes bombardment. Fortunes in shells are rained upon the enemy. An army will go to the greatest lengths to destroy enemy life and property, but it will go an equally great distance in the other direction to conserve and protect its own. This is the office of rubber. Wherever it is used it is always protecting something, keeping someone dry, shielding something from shock, conserving electrical power, preventing waste in a thousand different ways. It has done much to cushion this most brutal of games and to make it just a little more comfortable for those that play at it. We find it in every branch, and its work is always the same—conservation.

The biggest problem an army has to face is transportation.* New stores of food and munitions are constantly required. Large bodies of men must be moved rapidly from place to place. This has always been a problem. Napoleon failed in Russia because his supply trains could not get through. The influence of the railroad is well known and understood. Suppose we turn to the automobile and see what it has done. We find the motor used extensively on the battlefields of Europe. It has been estimated that our Allies have now in actual service 300,000 motor vehicles. We find them carrying everything, wounded, food, munitions, reinforcements. The battle of the Marne was saved by men who arrived by Paris taxicabs.

But the success of motor vehicles would have been impossible without the rubber tire. Nothing else transmits the tractive force so well. Nothing else rides so easily, with so little jar as the pneumatic tire. In our own country our highways take on a new importance—or rather an old importance. They are becoming once more "arteries of commerce." Trucks of all sizes, many with trailers, ply between our cities. Recent freight congestions have proved their worth. It appears that the vexing problem of long and short haul rates is to be solved by forces outside the Interstate Commerce Commission, for the day is not far distant when the railroads will not take any short haul business whatever and will concentrate on the long hauls, in which field they seems to be most efficient. The short haul belongs to the truck. Already manufacturers and stores are pooling deliveries. It remains for a few enterprising and far-sighted men to establish regular common carrier service. But even the long haul field is not inviolate. Recently an Akron rubber company installed regular Akron to Boston service. The experiment must have been successful or the fleet would not have been increased to five trucks. The running time going and return is one week. The secret of this success seems to be in the tires. These are of special extra large and extra heavy pneumatic cord construction. They plow through sand and mud roads almost as easily as they run on brick. The ordinary solid truck tire would be helpless in roads they negotiate easily. The completion of the Lincoln Highway has given a decided impetus to touring. Here again we find the pneumatic cord tire giving the best service of any in the field.

In France motor trucks are used mainly for short hauls from the railroad base to the front. But in the campaigns against Serbia and Russia the Germans used them quite extensively on long hauls. The average life of a solid tire is seldom over 2000 miles, less than one-tenth of that expected under ordinary conditions. Bad roads, shell holes, shell fragments, overloading, speeding, and all sorts of hard service in all kinds of weather are responsible. Repairs shops are scattered along the various routes.

Our Council of National Defense has estimated that an army of a million men will require between 30,000 and 40,000 motor trucks. This figure is probably low. It is not unlikely that before the war is over our army will number fully 4,000,000 men, requiring perhaps 200,000 trucks. Pneumatic tired automobiles in ambulance service, officers' cars, and motor lorries transporting whole companies with extreme rapidity, will likely number fully 100,000 more. The load which this particular branch of the rubber industry will be called upon to bear will be very heavy indeed.

The dispatch rider of a half a century ago is gone. He and his noble steed "flecked with foam" have given place to a mud bespattered streak—the motorcycle. With all our other means of communication it is still necessary at times to send written instructions. These the motorcycle rider carries with incredible ease and swiftness, over the very worst of roads and into the veriest of hells. The wear and tear upon his tires is perhaps the worst of any. The number of machines now in service with our army is not known, but bids were recently requested for 10,000 more. This is doubtless just the beginning for it is recorded that in the British army alone there are 100,000 machines in service.

FIG. 1—A SUPPLY TRAIN SOMEWHERE IN FRANCE

Figs. 1 and 3 from *Scientific American;* Figs. 2 and 5 from *Saturday Evening Post;* Figs. 4, 6 and 7 from *India Rubber World.*

But the part of the motorcycle rider is not alone to carry dispatches. There are companies of motorcycle scouts who are able, by reason of their swiftness, to perform feats impossible for Early and Jeb Stuart. The machines are often equipped with side cars carrying machine guns, thus rendering them many times more effective.

Physicians have laid most of the ills to which the enlisted man is heir, to bacteria, filth and exposure. The first two are overcome by vaccination and cleanliness, and the third by rubber. Our military leaders fully realize that a man who is dry and warm can stand most anything and do most anything. There will be no more standing unprotected all day in water up to the waist for our soldiers. In the British army hip boots for trench wear are a most necessary part of each soldier's equipment. In our army every man has either a slicker or poncho which serves him both as a rain coat and a ground sheet. Two ponchos laced together make him a fairly comfortable shelter tent. The poncho of our Allies is their ground sheet with which each soldier is supplied. The loss of these articles by troops in action is very high. It was estimated eighteen months ago

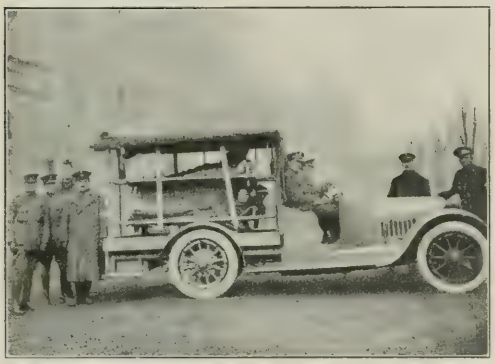

FIG. 2—AN AMERICAN AMBULANCE—UP TO THE MINUTE FOR COMFORT

that the total waste in rubber goods at the front reached fully 4000 tons daily.

Men in the motor truck service have rubber-proofed coats. Their machines are provided not only with rubberized tarpaulins but also with hoods which extend over and surround the driver's seat. Motorcycle riders are clad in a suit which is almost entirely rubber proofed. Ambulance drivers have rubber coats, boots and hats. Haversacks and knapsacks are also proofed with rubber.

This policy of protection from moisture is extended to nearly everything else. Light machine guns have their covers, as do also the delicate parts of the largest guns. Supplies of all kinds are properly protected by rubberized fabric. In this field alone rubber renders a most signal service.

The gas mask is but another illustration of the protecting nature of rubber. It has proved an effectual checkmate to German gas attacks. While a number of gases have been used it is now agreed that chlorine and phosgene are most often met with. The effects of chlorine have been known for many years, but the employment of phosgene was indeed a triumph for "frightfulness." This powerful and poisonous gas is known to the chemist as carbonyl chloride, $COCl_2$, and is produced by heating chlorine with carbon monoxide. The reaction follows:

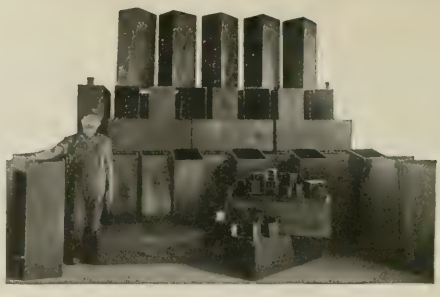

FIG. 4—BATTERY JARS FOR SUBMARINES

$$Cl_2 + CO \rightleftarrows COCl_2.$$

It is a colorless gas condensing to a liquid below +8 deg. C. At 0 deg. C. its specific gravity is 1.432, which is only a little less than that of carbon tetrachloride whose gravity is given as 1.63. Phosgene in the vapor phase is very heavy and tenacious. It is many times as poisonous as carbon monoxide and acts in much the same way, by adding on to the hemoglobin of the red blood cells, preventing them from functioning as oxygen carriers.

The gas mask is constructed upon simple lines. The hood is made of rubberized fabric and fits the head rather snugly. The eyes look out through rather large celluloid windows. A spring clamp with soft rubber buttons on the tips is provided for closing the nose, for all breathing must be done through the mouth. Incoming air passes first through a little metal box which contains the purifying chemicals, then through a hose which is connected to a rubber bit similar to that of a football player's nose guard. This bit is held firmly between the teeth. When exhaling, a little flapper valve opens and allows communication with the outside air. The life of a gas mask is not long. The gases are extremely reactive, and it is a credit to rubber chemists that it offers any resistance whatever. The outfit is neat, easily carried, and as comfortable as one could expect. The trick of breathing through the mouth is a little hard to grow accustomed to, but this is readily learned.

Another field in which rubber has rendered signal service is in the air. Rubber, while not entirely satisfactory, is still the best material for coating cloth which is to resist the diffusion of hydrogen. The gas bag of balloons is made of two or three piles of a very closely

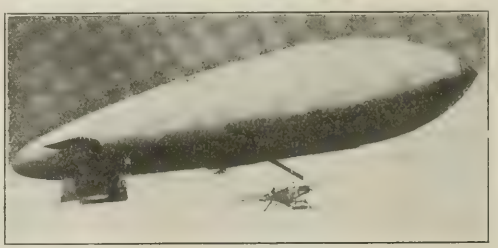

FIG. 3—A BRITISH BLIMP

FIG. 5—AN AEROPLANE IN FLIGHT (NOTE THE RUBBER TIRES)

woven and well proofed fabric. This proofing is applied by spreading machines on which the cloth receives a number of coats of rubber cement. The solvent is, of course, evaporated between coats.

Small captive balloons are used for observation purposes on sea and on land. With the advance in aeroplane practice it seems that their day is almost past.

This is not true, however, of the dirigible, called by our friends across the water "the blimp." Those building for our government have a gas bag shaped not unlike a great fish. Our first dirigible DN-1 is now fit only for training purposes. Its gas bag is 175 ft. long and has a maximum diameter of 35 ft.; 2500 ft. of double texture balloon fabric were used in its construction. Within the bag are located two balloonets, fore and aft. These interior gas bags are used in ascending and descending. To rise, the forward balloonet is emptied and the rear one pumped full of air. This disturbs the balance of the balloon, the nose is pointed up and it rises. To descend, the procedure is the same, but in this case the forward balloonet is filled and the rear one emptied.

FIG. 6—RUBBER SUIT FOR HYDROPLANE DRIVER

Sixteen dirigibles of a new type, modelled after the blimp of the British navy, were ordered by our government some months ago. It is understood that these are the first of a fleet of 300 which are to be used for coast patrol and search for enemy submarines. One of these recently made a trip from Chicago to Akron, about 400 miles, and covered the distance in sixteen hours. The advantage of a dirigible over an aeroplane as a submarine chaser lies in its lower speed. When its operators locate a U-boat, they can remain right over the place where it submerges. They will doubtless be provided with bombing devices and machine guns so as to be able to hold their ground until the arrival of the mosquito fleet. An aeroplane travels so fast that it can only say where the submarine was, not where it is. The blimps have given very satisfactory service in the British navy.

In the makeup of an aeroplane, rubber plays no small part. The wings are covered with rubberized fabric to prevent them from taking up moisture which would be simply a dead load. A very superior grade of rubber hose conducts the gasoline from its reservoir to the engine. Other hose is provided at points where the wire stays would cross. The valuable and extremely delicate instruments are protected from moisture by rubber. The machine runs along the ground on rubber aeroplane tires. On these it gets up its initial speed for the flight. When it lands the shock is taken up partly by cleverly designed rubber bumpers and partly by the tires. The insulation, which is so important, is rubber. Both the driver and his observer are protected from the cold and dampness of the clouds by rubber suits, hoods, and gloves. An apparatus which allows them to breathe in a rarified atmosphere is of rubber. They are in communication with one another through rubber speaking tubes.

FIG. 7—LATE MODEL AMERICAN DIRIGIBLE

The hydroplane, because of its contact with the sea, must be still more carefully waterproofed. The driver wears a rubber life belt, and his oxygen outfit will permit him to remain submerged for thirty minutes should he have an accident.

A modern battleship has been likened to a small city. On it are practiced all the arts of peace and war. Rubber is a prime necessity. We find the usual mechanicals—many different kinds of hose, air, gas, water, steam, armored, etc.; valves, gaskets, packing, washers; all kinds of belting; bumpers, shock absorbers for the great guns; insulation of all kinds; hard rubber knobs and handles for switches; rubber tile, matting, and rubber tired trucks. It is a floating fortress of steel. Its joints must be well packed and tight under all conditions. All that may be said of the virtues of rubber in a peaceful city applies here. The men have their rubber proofed slickers, suits, and boots for duty in stormy weather. Here again the importance of keeping the man dry is fully realized. Guns and munitions must be protected from the salt air. Floating as it does in water, there is a constant battle to keep things dry. Without rubber it would be very difficult.

Every ship in the U. S. navy has one or more divers aboard. These men are called seaman gunners and diving forms but a part of their training. Their principal

service is to examine the hull of their vessel or to recover something or other that may have been lost into the sea. The modern diving dress is made up of two parts, the bronze helmet and collar, and the elastic suit. In dressing the diver gets into his suit through the neck. There are but three openings, one at the neck and one at each cuff. At the feet the dress is attached to the heavy shoes. The dress is made of the best rubber sheeting placed between two layers of tanned twill. The cuffs are closed tightly on the wrists by means of rubber rings. There is an inner and an outer collar. The outer one is pulled over the breast plate to form a watertight joint. The helmet is screwed down upon his collar and made tight by a rubber gasket. The face plate is sealed in the same manner. The very best of hose is needed to supply him with air. It is hardly necessary to add that without rubber deep sea diving would be impossible.

In the building and operation of a submarine, rubber is of fundamental importance. It must be absolutely watertight and its packing and gaskets must be capable of resisting enormous pressures. Because of the necessity of running by electrical power while submerged the insulation problem is a big one. The interior of the boat is always damp and unless the wires and machines are adequately insulated disastrous short circuiting would result. Power is stored up in numerous batteries which must have their hard rubber jars. These are covered with sponge rubber slab to keep any electrolyte entrained in the evolved gases from leaving the jar.

Because of the extreme dampness the men are provided with rubber suits and boots. Rubber matting and tiling cover the floors and iron staircases. The periscope and other instruments are fitted with rubber bumpers and cases so as to protect both them and the operators from injury. In our navy the men are provided with rubber helmets for escape in case of accident. An important part of the torpedo is the rubber diaphragm by which its depth of submergence is regulated.

Our mosquito fleet consists of a rather large number of light fast boats which are more or less open. They must operate in all kinds of weather, consequently waterproofing and insulation are of primary importance.

Wherever electricity is used, insulated wire is necessary. Rubber insulation is still the most satisfactory material known. The best pliable insulation contains approximately 30 per cent of Hevea rubber. There are certain places, as for example, in the magneto of an aeroplane or automobile, where hard rubber insulation is highly desirable. The telegraph, telephone, and wireless telegraph are all of them dependent upon rubber for both hard and soft insulation. Electricians would be unable to handle high tension wires were it not for their rubber gloves.

In many steps of the manufacture of munitions rubber is called upon to protect the operator from serious injury. For example, in all the nitrating operations the men must be sheathed in rubber boots, aprons, and gloves. Again, a very small quantity of nitroglycerine causes an intense headache, and larger amounts may cause death. Rubber protection is absolutely necessary. When the munitions are completed rubber is called upon to keep them dry so that they may reach the field of battle in good condition. There are proofed bags for the powder and gun cotton, and rubber caps for shells.

The fine instruments, and modern warfare has developed a good many—the binoculars, telescopes, range fingers, compasses, chronometers, etc., must all be kept dry. Hard rubber often forms an integral part of them, and it is not uncommon to see their leather cases enclosed in rubber.

In the work of mercy, the care of the wounded, rubber also has its place. The soldier's first aid kit contains among other things a rubber tourniquet. The stickiness of his adhesive tape is due to rubber. The wounded man rides to the hospital in an ambulance whose floor is covered with rubber tiling. Many times he will be wrapped in a rubber sheet. The surgeons and nurses who meet him are attired in rubber aprons and gloves. He lays on a rubber bed sheet and his wounds are held together with rubber bandages. If he has fever, a rubber ice cap will cool his head; if a chill it is a rubber hot water bottle which is placed at his feet. If his wounds are serious and deep rubber tubing will carry the sterilizing Carrel-Dakin solution. If he is confined long, a rubber ring or pad inflated with air will ease him and prevent bed sores. Hard rubber enters into the construction of his physician's instruments, his catheters and syringes.

Rubber enters largely into the construction of life-saving equipment. Sailors in the British navy are provided with rubber collars which can be inflated in time of need. Cork is perhaps the most dependable, but it is bulky. A rubber life belt can be kept in the pocket and inflated when necessary. Life rafts float because of long rubber-proofed bags stuffed with cork or kapok, a silky fiber of great buoyancy.

When German autocracy crumbles, as crumble it must, it will owe its fall to four serious mistakes, all of which are directly traceable to what the athlete knows as overtraining and what the boy of the street calls "big head." They are:

(1) It thought Belgium would not fight.

(2) It thought England would remain neutral and the seas would be open.

(3) It took American patience for cowardice and decided we would not fight.

(4) It failed to appreciate the importance of rubber and to have a sufficient store laid by. Conditions are now so bad in Germany that even the wounded must do without it.

The first three we are not concerned with here. The fourth is typical of an autocracy overtrained in its own egotism. It prepared for war so effectually that it forgot to also prepare for peace. Now the penalty for being a liar is to believe the lie yourself. German propaganda spread the lie of German invincibility throughout the world, but the German himself came to believe it and this mono-mania will lead to his undoing. Rubber is so primarily a material for peace that the War Lord failed to note its importance for war.

Historians tells us that we have had on this earth of ours a stone age, a copper age, a bronze age, an iron age, and a steel age. Civilization has advanced and side by side with it, the art of war. All these materials are of such a nature that they serve both for war and peace. They are both destructive and constructive. How different it is with rubber. Its influence is preponderantly protective. The rubber industry is just beginning. Does it not augur well that the rubber age which is to come will be an age of peace?

The Mineral Industry—1892-1916

By G. A. Roush
Editor, The Mineral Industry

In glancing through the first volume of "The Mineral Industry" we find many statements and discussions that in the light of present day developments are very interesting and in some cases amusing, as no doubt many of the discussions of the present day will appear to the reader of a quarter of a century hence.*

For example, attention is called to the enormous developments that had been made in the five or six years preceding in the metallurgy of aluminium, emphasizing the fact that the price of the metal had been brought down to as low as 50 cts. per lb. and the production for the year, in the United States, was almost 300,000 lb., and the world's production almost 500 metric tons. The article closes with the statement, "It is doubtful if the further prosecution of the electrical methods, by which alone aluminium is now made, will bring the cost of it to the point at which it will become a prominent metal, unless they proceed along the line of direct reduction. Even here it is by no means certain that they can make it cheap enough. . . . While the electrical reduction methods are not to be condemned, those who seek by other means to make cheaper aluminium should be encouraged." Compare this with present conditions, with a United States production of 63,000 metric tons, a world's production of 132,500 tons and a production cost that has been estimated as low as 10 cts. per lb.

G. A. Roush

It is interesting to note that the coal production in the United States to-day is equal to the world's production as reported in 1892. The United States was then second in production with Great Britain leading, while the United States now leads with a production almost equal to the combined production of her two nearest competitors, Great Britain and Germany. These two for several years past have ranked very close together, with Great Britain slightly in the lead, while 25 years ago Great Britain's production was double that of Germany. Although these three great producers have changed order in the tables and have all seen enormous increases of production of from nearly 100 to over 300 per cent in the course of 25 years, the production of all three still bears almost exactly the same ratio to the world's production, namely, slightly over 80 per cent of the total.

During the period under review the world's copper production has more than trebled, while the production of the United States has increased to six times its former amount. The United States has always led in production, but during that time has increased from 45 per cent to almost 65 per cent of the total. Twenty-five years ago Spain and Portugal came second, Chile third, Japan fourth and Germany fifth; the order now stands Japan second, Chile third, Mexico fourth, Canada fifth.

With gold and silver the figures are no less interesting. The gold production of the world has quadrupled while that of the United States has trebled. Twenty-five years ago the order of production was United States, Australia, Russia, Africa. At present it is Africa, United States, Australia, Russia. The African production, due to the enormous developments on the Rand, has increased to over 14 times its previous value, and now leads with about double the production of the United States, its nearest competitor.

The silver, up to 1911, had increased about 60 per cent, but in the last five years there has been a rapid decline, due to the revolutionary activities in Mexico, the heaviest producer, so that at present the production stands only about 10 per cent higher than 25 years ago. Since the price has dropped faster than the production increased, the world's production of silver in 1915 was worth only about one-half as much as the production of 25 years ago. The rise of prices during the

*The material of this article has been taken by permission from advance sheets of Mineral Industry during 1916.

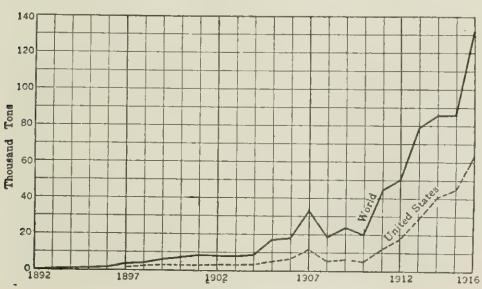

FIG. 1—ALUMINIUM PRODUCTION

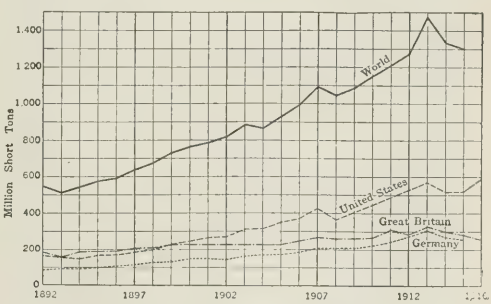

FIG. 2—COAL PRODUCTION

last year will, however, partly eliminate this discrepancy in value, and will reduce the deficiency in value from 50 to about 35 per cent. The United States started with a lead of 50 per cent over Mexico, the holder of second place, and ended with a production about double that of Mexico; but from 1902 to 1912 the Mexican production considerably exceeded that of the United States. The latter has shown an increase of about one-eighth, while Mexico has suffered such a decline as not only to wipe out the heavy lead with which she had held first place for 10 years, but has even pulled her considerably below her production of 25 years ago. Formerly Bolivia held third place, and Australia fourth. Mexico's position in second place is now being threatened by Canada, which formerly was far down the list, while Peru holds fourth place, and Australia has dropped behind Japan and Spain.

The production of iron ore in the United States now is about four times the production of a quarter of a century ago, and the pig-iron production has increased

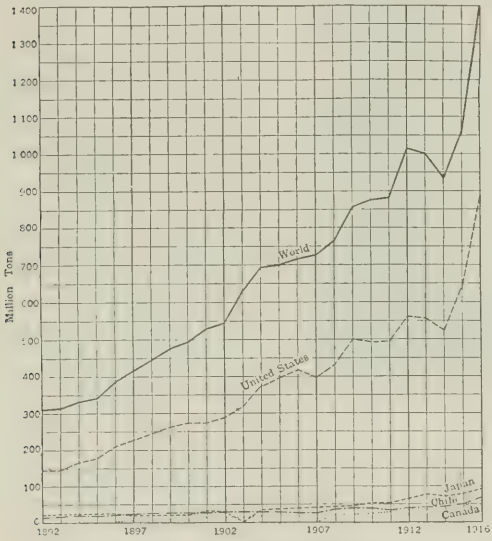

FIG. 3—COPPER PRODUCTION

in about the same ratio, while the pig-iron production of the world has increased to about three times its former amount. The order of producers is now United States, Germany, Great Britain, France, and Russia, with Austria-Hungary and Belgium practically tied for last place in the list of producers of more than 1,000,000 tons per year. The previous ranking was United States, Great Britain, Germany, France, Austria-Hungary, Russia and Belgium, with the last three all below the million-ton mark. Pig-iron production in the United States to-day is at a rate approximately a third greater than that for the entire world 25 years ago. It is true that the United States was in the lead in production then, but Great Britain was a close second, and the German production was over 50 per cent of the United States production. To-day the United States production is approximately 50 per cent of the world's production, or, in other words, is equal to that of all the rest of the world put together.

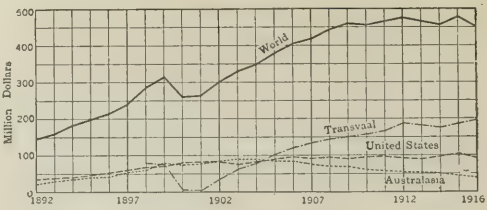

FIG. 4—GOLD PRODUCTION

The steel production naturally follows closely the production of pig-iron, and the order of production for the various countries is the same for steel as for pig iron, both at the beginning and end of the period under review. Due, however, to the development of processes which permit the use of greater proportions of scrap and waste material in the manufacture of the steel, and to the development of processes with higher percentage yields of finished steel on the raw material used, the total production of steel has grown faster than that of pig iron, and is now over five times what it was 25 years ago. And where the United States produced only a little over one-fourth of the former total, it now produces half, and the production of the United States has increased eight-fold.

During this period the processes used in the manufacture of steel have undergone a remarkable transformation. In 1892 almost 84 per cent of the steel production of the United States was made in the Bessemer converter, and 14 per cent in the open-hearth furnace. The corresponding proportions to-day are 26 per cent in the converter and 74 per cent in the open-hearth.

Lead production in the world during the past 25 years has approximately doubled. The ranking of producers at present is: United States, Spain, Germany, Australia and Mexico, all normally producing over 100,000 tons annually, but this figure has not been reached in Mexico during the last few years on account of the curtailment of production due to revolutionary activities. The former order of producers was the same as at present, except that Mexico was ahead of Australia. The heaviest increase was in the United States, amounting to about 260 per cent.

The enormous developments in the steel industry have demanded a proportionate increase in manganese production. The world's production is now about seven or eight times what it was 25 years ago, and there are

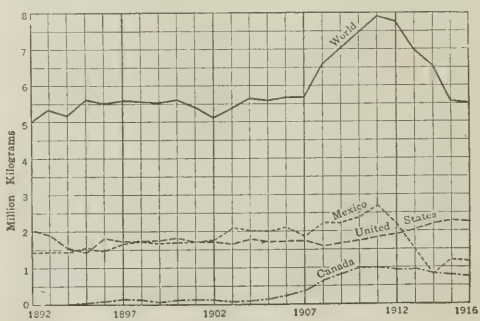

FIG. 5—SILVER PRODUCTION

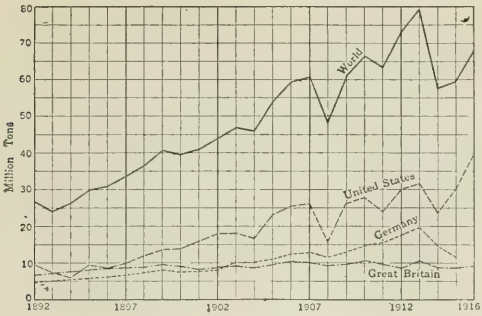

FIG. 6—PIG-IRON PRODUCTION

now three countries, India, Russia and the United States, with productions ranging from two to three times the world's production of 25 years ago.

The petroleum production of the world during the period has increased five-fold. In 1892 the producers showing more than 1,000,000 bbl. per year were the United States and Russia, together accounting for 97 per cent of the world's production. The present producers of more than 1,000,000 bbl. per year are, in order of production, United States, Russia, Mexico, Dutch East Indies, Roumania, Galicia, India, Peru and Japan. The United States now contributes 64 per cent of the world's production, as against 57 per cent 25 years ago, and now stands at about six times its former production. The Dutch East Indies, Peru, Argentina, Trinidad, Mexico and Egypt have entered the field as large producers during the period and now account for one-eighth of the total production.

The world's sulphur production is obtained almost entirely from Italy and the United States, with smaller amounts from Japan and Spain. Twenty-five years ago Italy was the producer of over 90 per cent of the world's supply, with most of the remainder coming from Japan. Consumption was on the increase, and the Italian production grew rapidly, reaching a maximum in 1905, when the production was nearly double that of 1892. Production in quantity in the United States began in 1903 and this soon reacted on the Italian production, which declined to about 50 per cent of the total.

Sulphur production during the 25 years has doubled, but pyrite production has more than trebled. Formerly France led in production, followed by Portugal, Germany, United States and Spain, all producing over 100,000 tons annually. The producers of that quantity

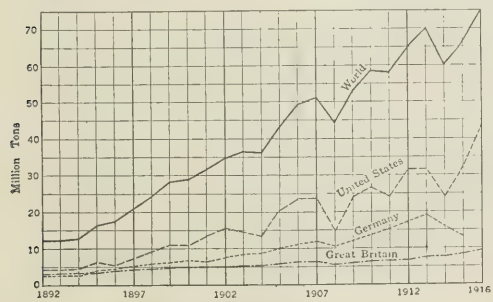

FIG. 7—STEEL PRODUCTION

at present are as follows: Spain, Norway, Portugal, United States, Italy, France, Germany, Canada, Russia, Japan and Hungary. Of all, Spain has shown the greatest increase, with Norway second. The Spanish production has jumped from 10 per cent of the total to nearly 25 per cent, and the Norwegian from 6 per cent to double that proportion. The United States production has just about kept pace with the total production.

The tin production of the world has, in the quarter of a century, almost doubled. Malaya still contributes a large share of the total, but has dropped from over 50 per cent almost to 40 per cent. England long held second place, but now Bolivia takes it with almost 20 per cent of the total, where formerly she was at the end of the list with 3 per cent. Banka still retains third place, having increased somewhat more rapidly than the totals. Australia and Billiton have both declined, the former the more seriously.

Tungsten is a metal that has seen almost its entire commercial growth within the period under review, and most of that within the last few years. The production of tungsten ores in this time has increased in a ratio of almost 50 to 1, two-thirds of which has been within the last five years. In the present production the United States accounts for 35 per cent of the total, Burma 22 per cent, Portugal 8 per cent, Australia 7 per cent, and Japan 6 per cent, all producing over 1000 tons annually.

Zinc production in the past 25 years has about trebled. Most of the leading zinc producing countries have been disturbed by the war to such an extent that recent figures are not available for comparison, but from the latest data available the United States was

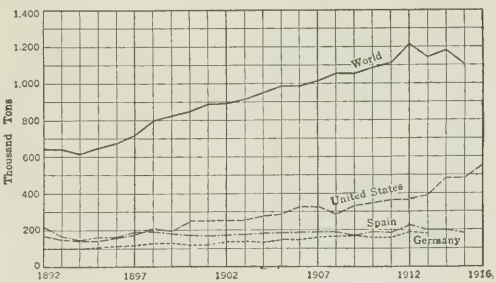

FIG. 8—LEAD PRODUCTION

the leading producer with Germany second, Belgium third, France fourth and Great Britain fifth. The former order was Germany, Belgium, United States, Great Britain, France. The United States has increased its production to eight times its former amount, and has increased its proportion of the world's output from 20 per cent to about 60 per cent.

It is of course absolutely impossible to make anything like a direct comparison between conditions now and twenty-five years ago, because now everything is on an abnormal basis. Some industries are swelled to beyond all semblance of their normal proportions by the extraordinary demands of war, while others are severely handicapped because of the disturbance of raw materials and markets, and the serious difficulties encountered in shipping, difficulties which are not by any means confined to trade with belligerent countries, but

extend also to the neutral countries and, in a large measure, to purely domestic shipping as well. However, in spite of all of the necessary readjustments, the period of the war has been, to most of the mineral and metallurgical industries, one of unparalleled prosperity. This is particularly true with aluminium, copper, iron and steel, tungsten, and zinc, which on this account have come to be classed under the heading of "war metals."

FUTURE DEVELOPMENTS AND INTERNATIONAL RELATIONS

What is in store for the future is difficult to foresee, but whatever may be the eventual outcome of the present conflict, it seems certain that the mineral and metallurgical industries will be called on to continue production to their utmost capacities in the work of restoration, and this will extend over a period of several years. It is to be expected that there will be somewhat of a slackening in speed after the conclusion of the war, for, however pressing may be her needs, Peace can never be the exacting taskmaster that War is; this slackening will be simply a logical outcome of the conditions, but it should not be of such proportions as to cause a serious slump in any industry as soon as the war demands are satisfied. On the contrary, manufacturing plants will be able to relax from the strain of war production and settle down to the fulfillment of the demands of peace and reconstruction at practically their normal capacity at the time. Of course it is not going to be possible after the war to keep the production curves of the various materials rising at the precipitous angle they have assumed during the war, for demand in many lines now is far above normal and is still increasing, but the normal course of the world's progress will soon bring it to a point where it can absorb these enormous productions, and it is quite possible that the demands of reconstruction will absorb the excess over a sufficient period of time to permit this condition to be realized, so that at the worst all the industries will suffer will be a period of a few years with little or no increase beyond the point at which they were at the close of the war, rather than a serious break in production and values.

The titanic forces of the present struggle are rapidly bringing to a head many conditions that normally would have required years of slow development. New industries are born over night and grow to a real semblance of maturity in weeks instead of years. Plant productions increase by leaps and bounds, doubling and trebling within the year under the impetus of an all-absorbing demand and an unprecedented price. New machinery and processes are developed and invention is stimulated in all branches of industry.

Since the opening of the European war the latter part of July, 1914, with its accompanying commercial

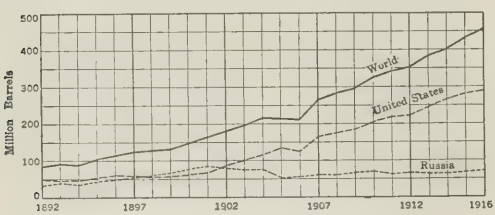

FIG. 9—PETROLEUM PRODUCTION

FIG. 10—SULPHUR PRODUCTION

disturbances, there has been a great deal of discussion in this country concerning the possibility of making the United States independent of foreign supplies in order to avoid future difficulties of this kind. This, of course, does not mean that all imports are to be discontinued, but that attempts be made to furnish domestic supplies of basic materials, in order that a whole industry may not be handicapped by the lack of some one material on which the process of manufacture depends. On analysis, however, this proposition does not prove to be as simple as it seems on the surface, particularly with regard to the mineral industry, either for the United States or for any other country. And, naturally, the smaller the country concerned and the more limited her resources, the more remote does any such possibility become. The discussion as here outlined is from the particular standpoint of the United States, but the arguments apply equally well, in a general way, to any of the other large mineral producing countries.

It follows from the natural course of human life and its needs that certain industries should be fundamental, and others secondary—or, in other words, that certain basic industries are concerned with the supplying of the prime necessities of life in their crudest forms, while the other industries are concerned with the modification of these crude forms through various stages of higher refinement, or with modifications of form, location, etc. Of these basic industries, probably none is more widely scattered over the face of the earth, more closely related to the general welfare and progress of the countries concerned and, in fact, more thoroughly universal than the mineral industry, with the

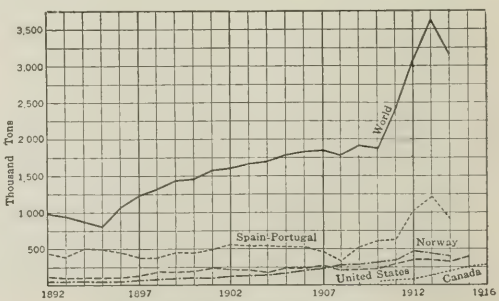

FIG. 11—PYRITE PRODUCTION

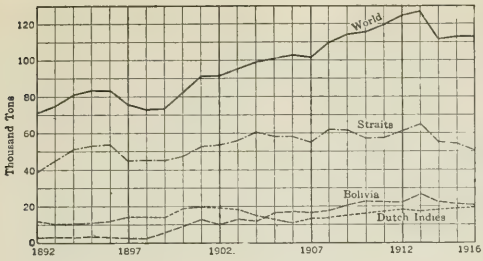

FIG. 12—TIN PRODUCTION

single exception of agriculture. In no other industry is the influence of a single locality so widely felt as in the mineral industry. For years the world went to Ceylon for its graphite, to Sicily for its sulphur, to the Ural Mountains for its platinum. A small district in the State of Arkansas furnishes the raw material for 65 per cent of the world's supply of aluminium. Chile furnishes practically the entire world's supply of sodium nitrate and Germany has supplied such a large proportion of the world's supply of potash, that the limitations of production and exportation resulting from the disturbances of war have made a shortage of this most necessary material throughout almost the entire world. And carrying things to the opposite extreme, it requires almost a page to list the countries that produce important quantities of the ores of gold, silver, copper or iron.

Probably every country and every state on the face of the globe has within its borders valuable mineral resources of one kind or another, of greater or less importance. In many cases it is something that is merely of local interest and importance; in other cases, such as those mentioned above, the materials are of international importance. Dana classes ice as a mineral, but its use purely as a mineral substance is probably limited to its employment as a building material in the arctic regions. Southern Indiana's Bedford limestone and Vermont's granite, however, while used for the same purpose, are naturally of incomparably wider application and value. When the production and use of any material is purely a matter of local interest, any knowledge or information concerning the industry involved in the production is also merely of local interest. But just as the breadth of the market and the scope of application of any material increases, so does the demand for information in regard to that material increase. The more general is the demand for the material itself, the more general is the demand for knowledge concerning the progress of the industries producing this same material in other localities, and on this demand for knowledge there can be placed no final limitation except one of degree. Other factors, geographical or political, economic or social, are contributive, rather than determinative.

The Arizona copper producer is interested more in the Montana production than in that of Utah, not because it comes from Montana, but because it is a heavier competitor in his market; but should the Utah production exceed that of Montana, Arizona's interest would follow the heavier producer, rather than remain in a given locality. Europe is interested in the Chilean copper developments, not because they are in Chile, but because they promise an additional amount of metal available for import into Europe, and the interest would be just as great if the deposits were in Fiji or Greenland.

As Kipling says, "The Colonel's lady and Julia O'Grady are sisters under skin." The laborer, the superintendent, the general manager, the New York capitalist, all have the same general interest, differing only in intensity and extent, depending on the contributing factors. The laborer makes his living from his work in the mines or smelter, and wants to know how things compare in the mine where he works and in the other mines in the neighborhood. The superintendent compares conditions in his own working district with the adjoining districts. The general manager in charge of plants in different parts of the country will consider matters on a still broader scope, and the capitalist will compare his holdings in this country with those in other countries. And so we have in every case, from whatever angle the question may be considered, an interest proportioned to the extent to which the individual is affected by the conditions within his own particular field of operations, as compared with other fields of similar work.

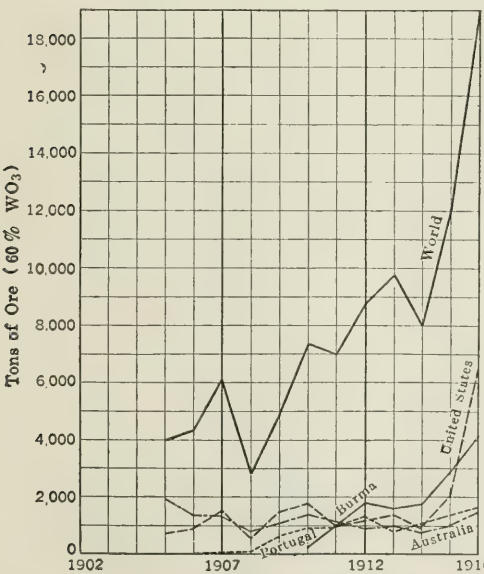

FIG. 13—TUNGSTEN PRODUCTION

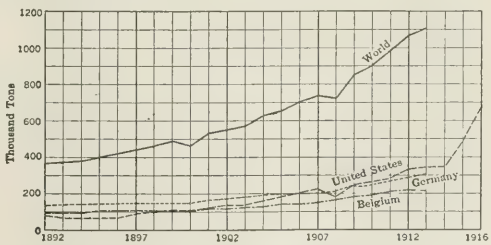

FIG. 14—ZINC PRODUCTION

The general interest thus manifested and the demand thus created for knowledge of the progress of an industry in different localities is inseparably linked with the economic dependence of each country of the world on most of the other countries. That stage of civilization when the world was made up of a number of independent districts is long past. A given locality can no longer produce within its own confines everything that is demanded in the course of its life. In the first place, civilization has reached a point where it demands more than it has in the past, and in the second place, economic development and the law of the survival of the fittest has led to an age of constantly increasing specialization, which, aided by increasing ease of communication and transportation, has brought things to a point where we now find ourselves dependent for one thing or another on almost every district of the civilized world.

This dependence can be well illustrated as the average man looks around his own home. He no longer lives in a house of his own building, eats food of his own growing, cooked in vessels of his own making, and wears clothes of his own weaving. In the average man's house we now see aluminium which probably originated in Arkansas, or possibly in France, and which, in the course of manufacture demanded cryolite from Greenland. He reads a newspaper printed from type containing lead from Missouri, Idaho, Utah or Mexico, and antimony from China. The asbestos pads on the stove came from Canada, and the polish on the stove from Korea, or possibly from Ceylon or Madagascar. The street in front of the house is paved with asphalt from Trinidad. The house is painted with barium from Germany. He frequently uses as a medicine iodine from Chile and bismuth from Bolivia. Such steel as he uses comes mostly from the United States, but the furnace in which it was made required magnesite from Austria or Greece, and as the steel came from the furnace it was deoxidized with manganese from Russia, India or Brazil. To make his stove bright and cheerful it is given windows which are glazed with mica from Canada or India. He gets his light at night from gas mantles made from monazite from Brazil or from electric globes, the tungsten filaments of which may have originated in the United States, but which are just as likely to have come from Burma or Bolivia. He uses nickel from Canada and tin from Bolivia or Malaya. He fertilizes his lawn and garden with nitrate from Chile and potash from Germany. His wife cherishes an engagement ring bearing a tiny diamond from South Africa, set in platinum from Russia, and dreams of some time having a necklace of "real pearls" from the South Sea Islands. They eat off china from Germany, with silverware that might have come from almost anywhere, and after dinner he smokes a cigar that he fondly thinks came from Havana.

So close is this association of the various countries in a commercial way, that any factor that disturbs one country will disturb several, through its commercial relations with the others, and anything that disturbs several will disturb practically all. An indication of this condition is the unanimity with which the contributors to the technical press mention the effects of the present European war on the various industries that they happen to be discussing. Almost without exception, these industries have been considerably affected by the war. Some have been stimulated and some have been retarded and disorganized, but very few have remained unaffected.

These two factors, the individual interest in other localities supporting a given industry, and the interdependence of the various countries on each other for adequate supplies of certain materials, make necessary the dissemination of general information in regard to the status of the various industries from time to time. There are in the various states and countries certain organized agencies for the collection and distribution of such information, and the technical press gives a large amount of general information along these lines. But there is still room for considerable expansion along this line. Information should be fuller and more detailed, and should be made available more promptly.

It is not to be expected with the present broad development of all the various industries that any country of importance can become entirely independent of others in the matter of mineral production. It is possible to become partly so by the fullest development of the domestic resources, but absolute independence is impossible, because no one country, not even the United States nor Great Britain, with all her colonial possessions, includes within its boundaries *all* of the almost infinite varieties of mineral products that are now demanded by our every-day life.

PERSONAL CO-OPERATION

The prime requirement for the best development of domestic resources is a thorough knowledge of those resources. And for the best results, this knowledge must be well disseminated and not be confined to a few people in the immediate locality. In other words, every available source of material should be thoroughly advertised—not necessarily by paid advertising—but by proper publicity in the technical press, in order that the information may be readily available to all who are interested. This condition is at present only partly fulfilled, and there is room for considerable improvement.

And next in importance after a thorough knowledge of domestic conditions, is an equally thorough knowledge concerning the various foreign sources of any given material. This is, of course, more difficult to secure, and information is not nearly so plentiful as for domestic conditions and usually the more remote the locality the more meager is the information. Many of the disturbances of the past three years in foreign supplies of materials would doubtless have been considerably lessened if importers had had a fuller knowledge of sources of materials. Too many had no information beyond their own particular source of supply. And in many cases the necessary information was very hard to secure.

All the evidence, then, points to the necessity of fuller information concerning both foreign and domestic supplies of materials. And since it seems impossible for any country to be minerally independent, let each at least exert a reasonable degree of care in the apportionment of its dependence, for the strain can be considerably lessened for all by a proper exchange of information. To this end, co-operation between the various agencies interested in the collection and dissemination of such information is to be encouraged and fostered to the utmost possible degree.

An Experiment in Scrubbing Carburetted Water Gas for Recovering Aromatics*

Robert J. Moore and Gustav Egloff

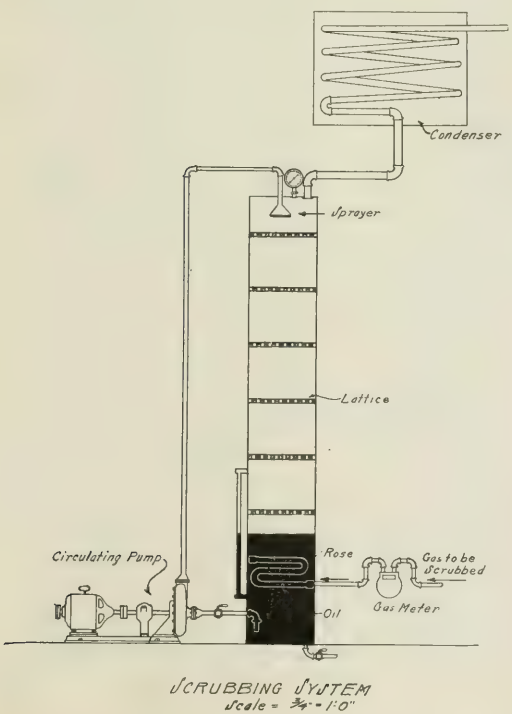
Considerable prominence has recently been given to the discussion of scrubbing carburetted water gas with a view to combating the shortage of toluene and benzene. The report, dated July 20, of Dr. W. H. Nichols, chairman of the Committee on Chemicals of the Council of National Defense, emphasizes the toluene shortage, and says that "efforts are going to be made immediately to increase this supply by 'stripping' the gas in large cities." In view of these facts the writers are of the opinion that the following experiment in scrubbing a representative water gas will be of interest to the oil fraternity.

EXPERIMENTAL

The carburetted water gas fresh from superheater was measured by passing through a dry meter and thence into an 18-in. diameter pipe 10 ft. in height (see diagram). In this pipe 25 gal. of technical paraffin "straw" oil was utilized for the scrubbing of the gas, which passed below the surface of the oil through a rose. As the gas passed through, the oil was circulated by means of a pump and sprayed over a series of lattice woodwork set within the pipe by means of supports. This circulation and spraying of the scrubbing oil facilitated the solution of the light oil molecules in the gas. Above the scrubber a condenser coil and box was placed so as to minimize the scrubbing oil losses.

Twenty-five gallons of straw oil were used in a charge. When 1000 cu. ft. of gas had passed through the system, the benzolized oil was transferred to a one-barrel still (42 gal. capacity), with adequate steam and condensing arrangements. This oil was steam and gentle direct-fire distilled until a temperature of 175 deg. to 180 deg. C. was reached in the oil vapor line. At this temperature practically all of the light oil distilled off. This fact was carefully checked by analysis of the original straw oil and the debenzolized straw oil as shown in the following tables.

*Presented at the fifty-fifth meeting of the American Chemical Society, Boston, Sept. 11-13, 1917.



SCRUBBING SYSTEM
Scale = 3/4" = 1'0"

TABLE 1
ANALYSIS OF ORIGINAL STRAW OIL
Distillations in standard Engler 100 c.c. flask at rate of 2 drops per second
Specific gravity 0.848/15.5 deg. C.

Temperature, Deg. C.	Per Cent by Volume	Specific Gravity 15.5 Deg. C.
310	1st drop	....
310 to 325	6.1	0.829
325 to 350	60.4	0.845
350 to 375	21.5	0.852
375 to 392	8.0	0.854
392 cracking	....	....

TABLE 2
ANALYSIS OF OIL AFTER STEAM DISTILLATION
Specific gravity 0.628/15.5 Deg. C.

Temperature, Deg. C.	Per Cent by Volume	Specific Gravity 15.5 Deg. C.
306	1st drop	....
306 to 325	9.7	0.833
325 to 350	55.0	0.844
350 to 375	18.7	0.851
375 to 389	10.0	0.855
389 cracking	....	....

Comparing tables 1 and 2 no greater variation is found than one usually finds in oil distillation by the Engler method, showing that all the light oil present after the scrubbing was removed by the steam and direct-fire distillation. Some loss of the straw oil occurred in operation, but all the light oil was recovered, as far as practicable, the conditions of the experiment approximating plant conditions.

LIGHT OIL RECOVERED

The light oil recovered was 1.211 liters per 1000 cu. ft. of carburetted water gas washed. This oil was yellow and had the characteristic odor of a cracked oil. Its unsaturated content was high, 35 per cent combining with 1.84 specific gravity sulphuric acid. Due to this high percentage it was necessary to control the velocity of sulphonation by cooling to zero degrees due to the considerable heat generated by the interaction in order to avoid loss of aromatics, either by evaporation or by combination at higher temperatures. The analysis of the light oil is given in table 3.

TABLE 3.
DISTILLATION ANALYSIS OF LIGHT OIL.
Specific gravity 0.868/15.5 deg. C.

Temperature, Deg. C	Per Cent by Volume	Specific Gravity
39	1st drop	....
39 to 75	3.8	....
75 to 100	55.2	0.867
100 to 125	24.9	0.869
125 to 150	5.9	0.868
150 to 175	1.0	....
175 to 200	0.8	....
200 to 225	1.1	....
225 to 250	0.1	....
250 to 300	0.7	....
300 to 325	1.4	....
325 to 350	4.0	0.831
Residue	1.0	....
Loss	0.5	....

In the above table the 6 to 7 per cent distilling at the higher temperatures is probably due to straw oil carried over during steam distillation.

The per cent by volume of the benzene, toluene and xylene cuts from the light oil are given below in table 4, together with the gravities and also the amounts of unsaturateds in each cut.

TABLE 4.
PERCENTAGE OF BENZENE, TOLUENE AND XYLENE CUTS AND UNSATURATEDS IN THESE CUTS.

Cut, Deg. C.	Per Cent by Volume	Specific Gravity	Per Cent of Unsaturated
Benzene (to 95)	51.8	0.866	46.0
Toluene (95 to 120)	24.1	0.869	18.0
Xylene (120 to 150)	6.0	0.868	24.0

This high per cent of olefins (table 4) formed in carburetted water gas as manufactured in the standard plants to-day would naturally be a retarding influence on the success of the scrubbing process, involving as it does a complicated low-temperature washing system and purifying of the aromatics with the losses attendant thereto. Therefore it may be feasible to adopt certain modifications in the water gas works with a view to decreasing the percentage of olefins formed. There has been much research along these lines, but little actual installation. The method of admixing to the blue water gas, hydrogen gas in order to decrease unsaturation has been shown by Whitaker and Leslie[1] to be of little use so far as the above problem is concerned, since their work indicates that low molecular weight olefins are not hydrogenated to any extent. Whitaker and Rittman[2] show the results of gas making under increased and decreased pressure, while Egloff and Twomey[3] find that cracking a gas oil at higher temperatures than usual effects a decrease in the per cent of olefins and increases the aromatic formation. It seems to the authors that in view of the necessity of obtaining toluene and benzene in larger quantities than now possible certain changes may be advisedly made in the water-gas machine involving either temperature, pressure or admixed gases so as to increase the yield of the above-mentioned by-products. Carrying out the preparation of the blue water gas independently of the cracking of the oil in the carburettor and mixing these products later may be a solution of the problem. Since the carburetor then is in a separate system, either increased or decreased pressure may be used in cracking as desired. Such changes may be feasible in view of the propaganda to change the gas standard from an illuminating basis to a heat unit. Or the benzene fraction with its high olefin content may be returned to the gas depriving the latter of only its toluene and xylene.

YIELDS OF AROMATICS FROM THE LIGHT OIL

To determine the percentage yields of benzene, toluene and xylene actually obtainable from the light oil obtained by scrubbing, 1 liter was carefully treated with sulphuric acid, neutralized with sodium hydroxide, washed with water and dried over fused calcium chloride. This dried oil was distilled in an efficient fractionating column and analyzed by a method already described.[4] The results were as follows:

	Per Cent by Volume
Benzene	22.1
Toluene	20.0
Xylene	5.1

THE VOLUME OF AROMATICS RECOVERABLE FROM 1000 CU. FT. OF GAS

Since the volume of light oil recovered from 1000 cu. ft. of carburetted water gas was 1.211 liters, or 0.032 gal., and the percentages of benzene, toluene and xylene are as given above, the volumes of these aromatics per 1000 cu. ft. of gas are as given below in table 5.

TABLE 5.
BENZENE, TOLUENE AND XYLENE RECOVERABLE FROM 1000 CU. FT. GAS

	Liters	Gallons
Benzene	0.267	0.0707
Toluene	0.242	0.0640
Xylene	0.062	0.0163

In view of the fact that the annual production of carburetted water gas is in the neighborhood of 150 billion cubic feet the above figures are significant.

The Resilience Test

By Henry M. Howe

A given specimen of steel, though ductile under common static tensile test, may be extremely brittle under the impact test of the Fremont type, Fig. 1, in which a nicked test piece, *A*, lying level and supported at both ends, is struck a sharp blow in the middle of its length by a falling ram, *B*.

It is certainly disquieting to learn that a form of brittleness exists which our present reception test, the static tensile test, cannot detect. It is of course possible that this form of brittleness cannot lead to failure under service conditions, but this is certainly far from self-evident. Indeed, the natural presumption is that it may lead to failure, and that, in not attempting to detect it, we put ourselves in the position of the cashier who, though knowing that the market is flooded with detectable counterfeits, takes no efficient steps to detect them, but accepts all deposits at their face value.

I believe that the present evidence goes far to prove that the static tensile test does not and cannot determine the fitness of material for resisting shock when in pieces which are threaded, nicked, or of equivalent abrupt change of section, and hence that for such services this test should be supplemented by an impact test.

When we reach this point, we find ourselves confronted with a very difficult choice between various tests, carried out under radically different conditions.

Before taking these up let us agree on our terms. Here are those which I propose:

Resilience is now used as the measure of the work done in breaking the test piece by a shock test. It is the product of the average resistance to deformation up to rupture into the deformation before rupture, and thus it corresponds in a sense to the product of the tensile strength into the elongation of the static tensile test. It is measured in kilogram-meters (kg-m.). It is perhaps more usefully regarded as the measure of the ability to resist shock, or *"shock resistance."* As the static tensile test tells whether a test piece is statically strong or weak, so the impact test tells whether it is *resilient* or *irresilient*. Impact-resistance is more accurate than resilience.

Beyond this, the impact test tells us the degree of deformation before rupture under shock. This we may call the *"shock ductility,"* corresponding to the elongation and the contraction area of the static test, which we group together as "ductility."

Thus, both file steel and rivet steel are irresilient, for the file steel offers great resistance to each unit of deformation, it breaks before deforming greatly, and though rivet steel deforms greatly, it offers but little resistance to the unit of deformation because of its low elastic limit.

Turning now to the methods of test, the resilience, or work done in rupture, is determined by subtracting

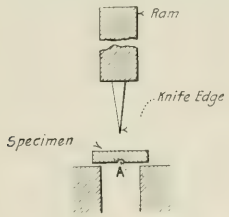

FIG. 1—THE FREMONT NICKED BENDING IMPACT TEST

from the total energy of the blow the residual energy left after breaking the test piece.

Two prominent types of testing machine need attention, those with a vertically falling ram of the Fremont type, Fig. 1, in which the residual energy is measured by a spring against which the ram strikes after breaking the test piece, and those with a swinging pendulum, the impact of which breaks the test piece, Fig. 2. The pendulum then swings on past the fragments of the test piece, and the height to which it now rises is the measure of the energy residual after causing rupture.

Instead of being broken by bending, as in Fig. 1, the test piece may be broken tensilely, by setting its length parallel to the path of the falling ram or tangentially to that of the pendulum.

Finally, the test piece may be either notched or plain, or, as I have suggested lately, threaded throughout its reduced section.

To the Fremont or vertically falling ram type it is objected that the mechanism for measuring the residual energy is untrustworthy, whereas the pendulum type has no corresponding defect, because the height to which the pendulum rises after passing the test piece is not subject to error or to misreading. The objection to the Fremont type is supported by an enormous mass of evidence showing extreme irregularity of results, though in some cases the concordance has been good. Its advocates explain that this represents heterogeneousness of the material tested, an important concession to which I shall return. The validity of this explanation can be tested readily, one believes, by testing the machine in blank, dropping its ram repeatedly from various heights, and noting whether for given height the energy indicated by the dial is constant.

To the bending type of test piece it is objected that this determines primarily the properties of the test piece at one spot only, the outer fiber immediately opposite the point of impact, because the properties of the metal at this spot have a wholly disproportionate influence on the apparent resilience of the piece and on the angle bent. A heterogeneous metal would appear resilient or irresilient, ductile or brittle, according to whether this part of this outer fiber happened to lie in a strong or a weak part of the bar, for instance to include or to escape a local flaw.

To nicking a like objection is made, whether for tensile or bending tests, that the properties of the material in the nicked section have a disproportionate influence in determining the resilience and ductility.

This objection applies with double force to the nicked bending test, for whereas in the nicked tensile test the whole of the cross section at the nick resists the stress relatively uniformly, in the nicked bending test it is solely the material at the apex of the nick, *A* of Fig. 1, that has this disproportionate influence in determining the resistance to rupture. We of course wish to learn the properties of the material at its weakest part. For a piece to be used in tension we wish to know the properties of the weakest section. Hence in our test it is the properties of the weakest section that we seek. Clearly, in a heterogeneous material the chance that the weakest place will happen to lie just at the apex of the nick of a bending test piece is less than that in a nicked tensile piece it will happen to lie somewhere in the nicked section.

Unfortunately, there is much to indicate that the nick is a necessity in testing materials for service in which the object itself is nicked, for instance those in which there is a screw thread. Direct comparative tests tend to show that certain material which has fair resilience when unnicked is very fragile when nicked, and that nicking may reverse the order of fragility of two materials. If this is true, if nicked fragility cannot be inferred from the results of an unnicked test, then I do not see how nicking can be avoided for nicked services.

But there is a special form of nicking which is not open to the objection that it localizes the application of the test, so that it is likely to escape the weaker parts of heterogeneous material, and this is to thread the

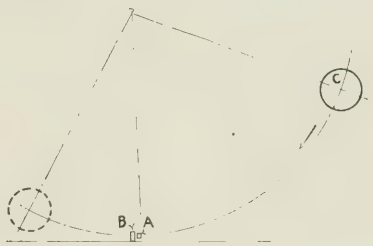

FIG. 2—THE CHARPY PENDULUM FOR IMPACT TESTING.
A—The test piece for the bending test.
B—The support.
C—The pendulum.

whole of the reduced section with a sharp spiral thread. With such a thread, rupture should occur at the weakest section in the reduced part of the test piece. The merit of such a suggestion can be learned only by thorough trial.

The nicked bending test is said to be much cheaper to make than any other.

The objection to the bending test and to nicked tests in general—that they are likely to miss flaws, defects, and local weaknesses due to segregation or to foreign bodies or sonims—evidently decreases in force when applied to material known to be extremely homogeneous. For instance, it may prove that the objection should be

waived in the case of crucible steel and of electric steel cast in ingots as small as those usual in the crucible process. Again, it may prove that etching tests may establish the homogeneousness of the material so fully as to justify waiving these objections in view of the cheapness and convenience of the nicked bending test. In that case, material which is shown by etching to be heterogeneous might have to pass a special threaded impact tensile test, while for that shown to be homogeneous the nicked bending test could be used.

Before we can put ourselves in a rational position by adopting a resilience test so as to detect and reject irresilient material for impact services, we need much more light on questions such as those which I have raised, as to the relative merits and the applicability of the several methods of test.

Here two questions seem of extreme importance. First, is there any one form of impact test which will measure the resilience for both nicked and unnicked services, for objects with a screw thread or its equivalent sharp change of section, and for plain objects which lack these changes? On the general principle that the conditions of the test should reproduce the most trying conditions of service, a nicked test is certainly indicated for nicked services. Yet for unnicked service a nicked test seems inappropriate, calling upon the material to possess a quality—ability to resist impact when nicked—which will never be utilized in service and hence is not needed. To provide it is to tax the user and through him the public needlessly. Hence we should learn whether the degree of unnicked resilience can be safely inferred from a nicked impact test. A possible way of answering this question is to apply the nicked test to unnicked objects which, in service, have a relatively small factor of safety and occasionally break; for instance, railroad axles and those parts of motor cars which fail most often. Collect a large number of such objects of which some have failed quickly while others have shown great endurance, and others still have endured only tolerably well. Determine whether a nicked test gives a fair measure of their relative merit.

Conversely, determine how fair a measure of their merit is given by an unnicked test.

Proceeding on the same principle, determine whether a nicked test is really needed for nicked services, or whether the indications of an unnicked test can be trusted. An examination of the existing evidence may well show that for nicked service a nicked test is indispensable. If it does not answer this question fully, then an answer could be had by applying an unnicked test, parallel to that which has just been outlined, to objects some of which, in nicked service, have shown themselves excellent, some bad, and some tolerable.

The second of the important questions concerns the trustworthiness of nicked tests in general. If the investigations already outlined should show that only by a nicked test can fitness for nicked service be determined, then we should have to consider whether the results of test with a single nick are trustworthy, and, if not, whether the test piece should be threaded and tested tensilely. If the great irregularity of the Fremont results, which is certainly very far in excess of the irregularity of static tensile tests on like materials, is traced to defects in his method of measuring the resilience, we should turn to the pendulum machine and determine the concordance of the results to be had with it, both with nicked bending and with nicked tensile impact test pieces. If neither of these gave concordant results, we should consider the relative merits of the tensile impact test on test pieces threaded instead of being nicked, and of arriving at a trustworthy result by manifolding the single-nick tests, and thus getting a number of results large enough to form trustworthy evidence of fitness, the smallest and not the mean resilience being taken as the true measure.

To perfect and carry out the details of such a program would imply so much work that it might well be undertaken by a commission. To our great consumers, such as the railroads and the makers of motor cars and of electrical machinery, the need of a trustworthy measure of resilience, a trustworthy means of detecting fragility, is so great that they ought to be willing to co-operate in forming such a committee.

The chief questions to be answered may be summed up thus:

1. Can either the nicked or the unnicked test be made to give trustworthy results of fitness for both nicked and unnicked impact service?

2. With materials of such a degree of heterogeneousness as ought reasonably to be provided for, can a single-nicked test piece give a trustworthy measure of resilience?

3. If not, is it more expedient to substitute a two-inch threaded length of impact tensile test piece for the single nick, or to test of each material so large a number of test pieces as to insure detecting approximately the weakest section?

Zinc Furnace Temperatures—I

Data on Different Kinds of Ores and Furnaces

By Edward Mackay Johnson
Superintendent Eagle Picher Lead Co.

NATURAL GAS FURNACE, COMMON RETORTS

The following temperature data were obtained by the writer on a natural gas furnace with common retorts. They indicate the temperature in the open retort as indicated by Norton cones.

The cones were placed at the back end of the retort, in the middle row, near the middle part of the furnace. The time was recorded when the top of the cone bent over to the clay. The firemen were in no case requested to use the cones as a guide in firing, but merely record the time when the cones went down. It was found, however, that some of the men would take an interest in the cones and even use them as an additional guide in firing. This was especially true of new firemen "breaking in." The cones certainly act as a warning with respect to getting "butchers" as in some cases it was found safe to get No. 7 cone down, with other ores No. 8, and in exceptional cases start No. 9.

Table I represents the average of the daily records, and the writer feels that they are not very far from the temperatures existing in the open retort during the distillation period.

REGENERATIVE FURNACE, HYDRAULIC RETORTS

The temperatures in Table No. 2 were obtained with a regenerative type of furnace using hydraulic retorts. As before they indicate the temperature in the open retort as indicated by Norton cones. The cones were placed at the back of the retort in the bottom row

All times represent the average reading for two months.

about the middle of the furnace. The time was noted when the cone had bent over to touch the clay.

From a comparison of Tables 1 and 2 it will be observed that there is considerable difference between them with respect to the Western ores, while upon the Joplin ore they agree more closely. This is mainly due to the fact that some metallurgists when treating Western ores bring the furnace along somewhat faster and work it off closer, while others bring the furnace up slowly, holding it a little greener in the morning, and thereby obtaining more metal at the third draw. If the recovery be the same in both cases the latter method is to be preferred, as it is easier on the retorts, the men, and the furnace.

COAL-FIELD FURNACE, HEGELER TYPE

The following is a log of furnace temperatures taken between the retorts in the laboratory of a coal-field furnace of the Hegeler type, with no regenerators; 1¼-in. slack coal was used, and the furnace operated on Joplin ore. Charging of the furnace was commenced at 5 a. m. and finished at 11 a. m. The draft in the furnace was from 2 in. to 2¾ in.; in the producer it varied from ½ in. just after coaling to 4 in. just before recoaling.

General average		1220	1232	1165	1205

CONCLUSIONS

There is too much variation in the volume of gas just before and after coaling up when using 1¼-in. screenings in a Hegeler producer for a non-regenerating type of furnace, due to the rapid combustion of such fine coal. This necessitates more frequent coaling up, and a consequent slight cooling of furnace. The fine coal with no steam blown into the producer forms large lumps of clinker, thus prolonging the clinkering time unduly. By coaling up once an hour there was a sufficient volume of gas of very good quality, and as seen from the temperature record in Tables 3 or 5 the furnace picked up very well during the first stage of the operation. It was, however, very difficult at the latter part of the process to force the backs (*i.e.*, from the 10th to 15th section) without retarding and even cooling off the fronts. The troubles were also aggravated by the increased charging time due to the great amount of producer ash carried into the furnace laboratory, thereby forming an unusual amount of glaze in the furnace bottoms and upon the back lining and retorts. Under these conditions there is hardly any question but that the four-row furnace would at least give the best recovery.

Table 5—Recapitulation and Deductions from Tables 1 to 4; Joplin Ore

Reference	Location	Time When Temperature was Attained of Charging: Cone 03 1090° C.	Cone 01 1130° C.	Cone 2 1170° C.	Cone 4 1210° C.	Cone 6 1250° C.	Cone 7 1270° C.	Cone 8 1290° C.	Cone 9 1310° C.	Start A.M.	End A.M.
Table 1, part 1	Open retort	1:20	2:57	5:10	7:55	9:48	12:00	1:10		4	9
Table 2, part 2	Open retort	12:40	1:50	3:45	5:40	7:55	10:30	1:15	3:20	5	11
Table 3, column 1	Laboratory*	11:55	1:03	5:00	8:00	10:20	12:20	5:00		5	10
Table 4	Laboratory†	11:00	12:00	2:00	4.00	6.00	8:00	10:00	12:00	5	10

*The approximate time noted on this line was taken from the first column of Table 3, and therefore corresponds to the 4th section only.

†Interpolated from the temperature at four o'clock which was 1205° C. according to Table 4.

An examination of Table 5 seems to show it in error that it indicates temperatures in the laboratory at a later time than the same temperature in the retort. This seems unreasonable, inasmuch as the heating atmosphere must attain a certain heat before the heated body. These comparisons of temperatures, however, are made on furnaces of different type, and merely confirm the actual facts that the furnace in question did not pick up in heat fast enough, and the blue powder could not be worked close enough. Consequently the recovery was unsatisfactory.

Opposite is an analysis of clinker, glaze and slag:

	SiO_2	FeO	CaO	Al_2O_3
Producer clinker	45 5%	15 9%	11 5%	24 3%
Retort glaze	61 6	13 7	4 7	20 3
Furnace bottom slag	53 9	9 5	5 4	27 1

The Gambler

Safety Bulletin, Illinois Steel Co.

A gambler is a man who stakes something of value on an uncertainty. It matters not what that something is. It may be money, health, happiness or life itself, but if he pits it against chance, if he wagers it on a fortuitous turn of life's wheels—he is a gambler, pure and simple. There are many men who would consider themselves defiled if they even so much as fingered a playing card, or looked with sympathetic eye upon a game of chance, who daily jeopardize their lives with unnecessary risk of accident, or injure their health in useless exposure.

It is right enough to have our scruples in connection with those things which the world deems bad, but let us be consistent; let's come clean on this business of taking a chance.

The chance taker is a peculiar menace in the railroad ranks. If, through thoughtlessness, he injures or kills himself, there is untold suffering to those who love him, his own hopes and ambitions stop short of fulfillment and a producer has been removed from his proper place in the general scheme of things.

If, through negligence, of failing to think, the chance taker causes the injury or death of a fellow employee, there must be added to all of the other suffering, a consciousness of his own failure to abide by the simple principles of safety and caution.

It matters not how straight laced a man may think he is, there is something wrong with his morals when he does not feel and constantly endeavor to live safely and sanely, with due regard to his own life and the lives of those about him.

God gives every man the right to live, and if he trifles with that right or with the same right possessed by his neighbor, he is a dangerous gambler and not cognizant of his moral responsibilities.

It's a great mistake to think there is no religion in the rule book. The rule book was not published by a church, but a railroad man cannot be a good churchman, unless he tries to live up to the rule book.

Let's cut out gambling in human life, and try to live straight!

The Research Corporation, incorporated in 1912 by Dr. **F. G. Cottrell** to administer his patents on electrical precipitation of suspended particles, has decided to offer a fellowship of the annual value of $2,500 for the purpose of encouraging scientific research in the development of the industrial arts. The fellowship will be awarded after competition consisting of the submission of evidence of scientific attainments, discoveries or inventions and of special fitness for advanced work. The competition will be decided on Dec. 1, 1917, and the successful candidate will be required to begin his research or investigation immediately. Each fellow is required to present a written report of the results of his work to the corporation at the conclusion of his appointment, but any discovery or invention which he may make shall be deemed his personal property.

Some Notes on Nitrating Kettles with an Example of Acetylation Apparatus

By Frederick Pope

Nitration is ordinarily carried out in metal vessels, sometimes cooled and sometimes heated. For many purposes, however, it is advisable or even necessary that nitration be conducted in vessels of earthenware,

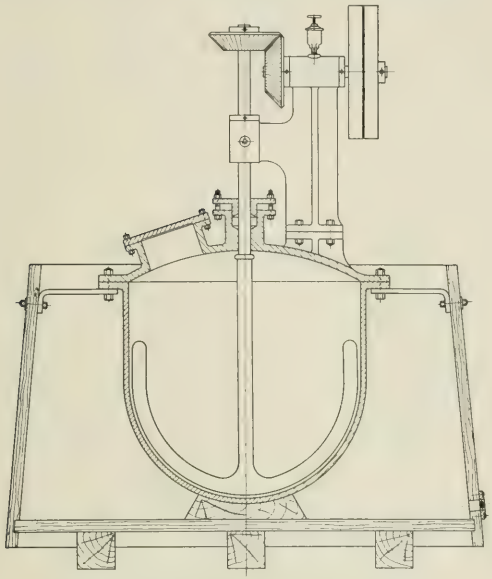

FIG. 1—SIMPLE FORM OF NITRATING KETTLE

glass, enameled or special acid resisting metal such as corrosiron, duriron, tantiron, etc.

The nitrating agent is ordinarily nitric acid, mixed nitric and sulfuric acid, or one of the alkali nitrates, sodium nitrate, for example.

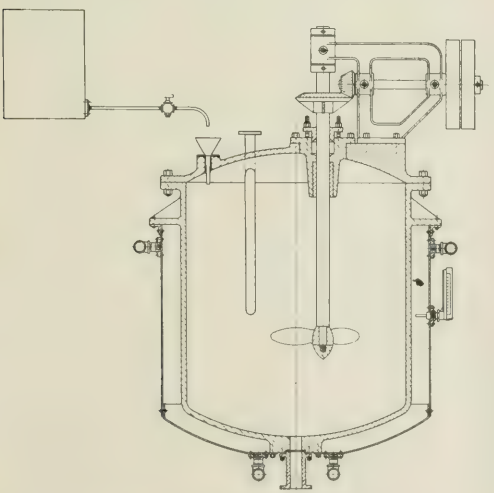

FIG. 2—ORDINARY SMALL NITRATING KETTLE

Fig. 1 shows what is perhaps the simplest form of nitrating kettle, one seldom found in the United States, although not uncommon in Europe. It is a simple cast-iron kettle provided with a mechanical stirring device, set in a wooden tub so arranged that the kettle may be surrounded with either water or ice water. This kettle is discharged either by blowing or with a siphon.

Fig. 2 shows an example of an ordinary small nitrating kettle, arranged for cooling or gentle heating, hot water or low-pressure steam being used in case heating

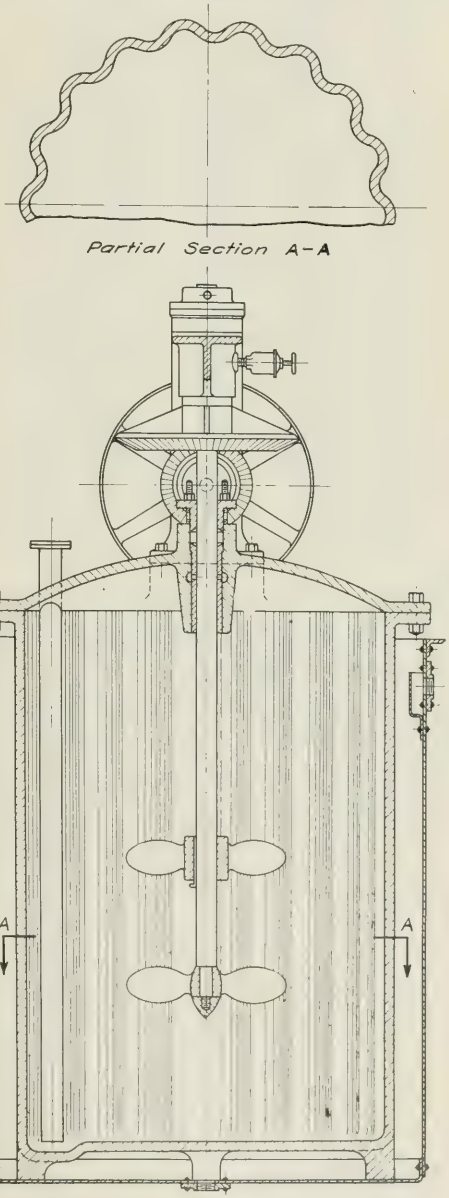

FIG. 3—NITRATING KETTLE WITH CORRUGATED SIDES

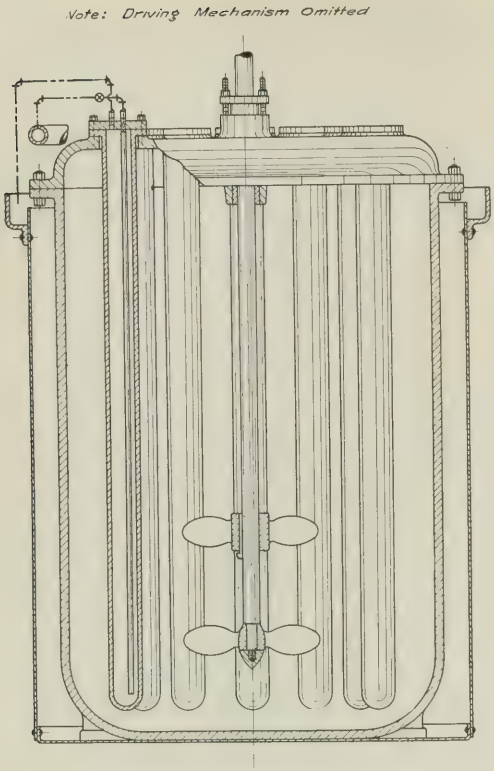

FIG. 4—DESIGN FOR LARGE KETTLES

is desirable. For either brine or water there must be a number of inlets at the top and a number of outlets at the bottom, arranged so that the water or brine in circulation will not channel.

In many instances the rate at which nitration can be carried on is determined by the amount of cooling possible. To promote rapid cooling, a number of expedients have been resorted to.

Fig. 3 shows a nitrating kettle, the sides of which are corrugated so as to present a greater surface for cooling than an ordinary round kettle. This is a somewhat difficult casting to make, and is a type which has not met with very great favor in this country.

Another method is to provide closed-end tubes extending into the liquid in the kettle from the top, as well as a jacket surrounding the kettle. This is illustrated in Fig. 4. By this means the cooling surface is increased very considerably, and this design is used extensively in large kettles. Nitrating kettles of this sort, with a capacity from twelve to fifteen hundred gallons, are largely used for nitrating benzol.

When neither low temperature nor a rapid abstraction of heat is necessary, the cooling is accomplished by cooling water. A kettle equipped with a jacket, such as shown in Fig. 2, is often used.

Fig. 5 shows an earthenware apparatus for nitration. This is set in a vessel so that it may be surrounded with cracked ice or ice water. A tub similar to that shown in Fig. 1 is often used.

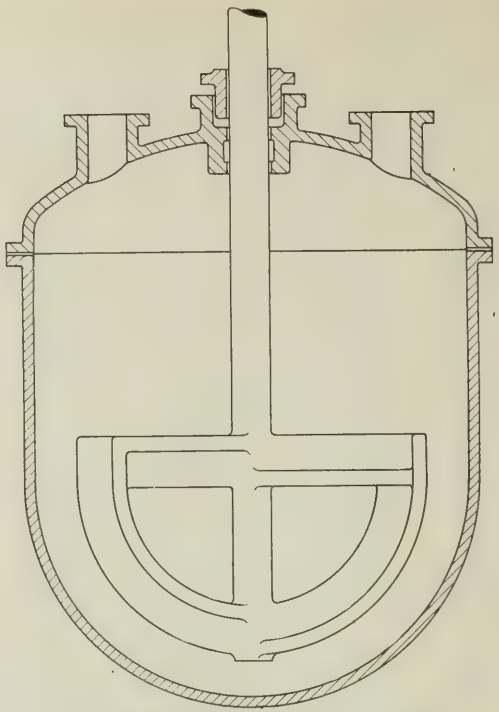

FIG. 5—EARTHENWARE NITRATION APPARATUS

For some nitrations where heating to comparatively high temperatures is necessary we use an apparatus such as shown in Fig. 6. Here the heating is accomplished by steam of a sufficiently high pressure to give the desired temperature or steam superheated to give the desired temperature.

Mononitration and dinitration of a variety of substances are successfully carried out in continuous apparatus. Fig. 7 shows one form of nitrator used for continuous nitration, which has been very successfully used, particularly in the manufacture of nitrobenzol. The cooling here is accomplished by the circulation of water through the coils marked *d*, as shown in the drawing; *a* and *b* are inlets for benzol and acid respectively; *c* is the outlet for nitrobenzol. Accurate results are possible in this apparatus, which is very nearly automatic.

Fig. 8 shows complete apparatus for continuous nitration. Benzol from the tank *b* enters the column *a* through the tube 1. The mixed sulfuric and nitric acid from the tank *c* enters the column through the tube 2. The spent acid leaves the column by the pipe 3, and is collected in the tank *d*. The crude nitrobenzol as produced in the column *a* leaves through the pipe 4 through the watch glass *e*, entering the washer *f*. The wash water enters the washer through the pipe 5 and leaves through the pipe 6. The washed nitrobenzol leaves the washer through the pipe 7, passing through *g*, where it is heated, enters the column *h*, through the pipe 8, which acts as a refining column. The purified nitrobenzol leaves the column by the pipe 9, passing into the cooler *i*. It leaves the cooler through the watch

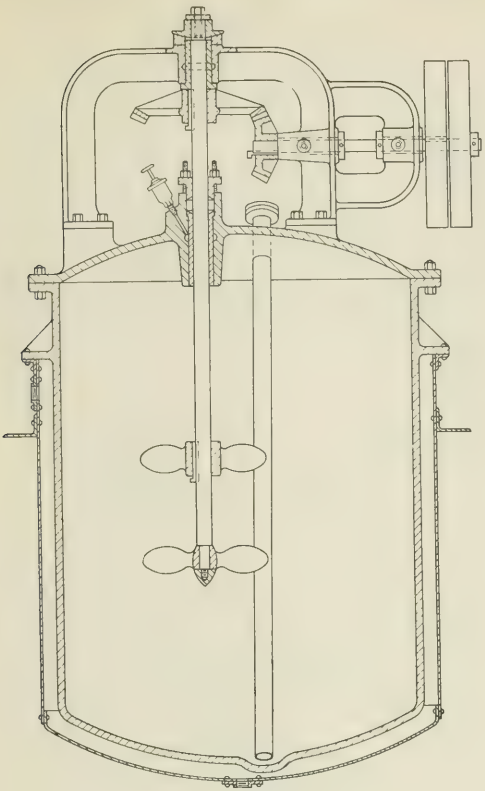

FIG. 6—APPARATUS FOR HIGH TEMPERATURES

glass *j*, enters the separator *k*, where the pure nitrobenzol passes off through the pipe 10 and the water through the pipe 11. The excess of benzol which has been distilled from the nitrobenzol leaves the column *h* through the pipe 12, passes through the partial condenser *g*, enters the cooler *l*, passes through the watch glass *m* and into the separator *n*. The benzol from the pipe 13 is returned to the tank *b*, while the water passes off through the pipe 14. Steam is admitted into the column *h* through the pipe 15. Cooling water for the nitrating column enters through the pipe 16 and leaves through the pipes 17.

A nitrating kettle must always be provided with a cover, usually of the same material of which the kettle is constructed. The joint between the kettle and the cover is usually made with asbestos, rubber or other material, the nature of the joint being determined by the material treated, the material of which the kettle is made, and the pressure to be carried within the kettle. For some materials, asbestos and silicate of soda is very successful.

A variety of agitators are used in nitrating kettles. The off-center propeller, such as shown in Fig 2, is for many purposes the most advantageous. For a large class of nitrations the simple gate type of agitator, such as shown in Fig. 5 for an earthenware kettle, is entirely adequate. Two off-center propellers on the same shaft, the propellers throwing in opposite directions,

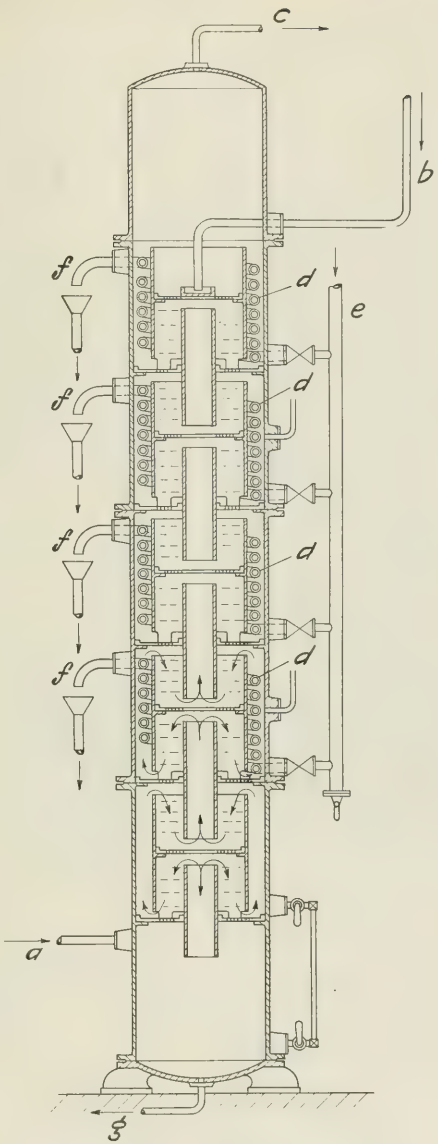

FIG. 7—CONTINUOUS NITRATION APPARATUS

as in Fig. 6, are especially good for large kettles.

When the propeller type of agitator is used, care must be taken that the propeller suits the condition. There is one correct speed for a propeller, which depends upon the size and shape of the kettle, size, form and pitch of the propeller, and the consistency of the liquid in the kettle. With all these conditions determined, there is one correct speed of the propeller. If this is considerably departed from, its efficiency as an agitating device is materially decreased. It follows then that if the consistency of the liquid in the nitrating kettle changes considerably in the course of nitration the propeller type of agitator is unsuitable.

Fig. 9 shows a stirring device which is used when solids such as alkali nitrates are used in nitration. In some cases it is necessary to go beyond the precautions taken here, and the lower blade of the stirring device is made in the form of a rake.

Fig. 10 shows a complete nitrating arrangement where brine cooling is necessary. This would illustrate, for instance, an installation for the nitration of acetanilid, making paranitracetanilid; *a* is nitrating kettle, *b* is an acid reservoir, *c* a brine tank, *d* a brine pump, *e* an ammonia compressor, *f* an ammonia condenser, *g* an ammonia receiver, *h* ammonia expansion and cooling coils, and *i* a reservoir.

The system is too well known to require more than the barest description. Ammonia is compressed and then passed through an ammonia condenser, where it is cooled and then allowed to expand, passing through pipes in the brine tank, and cooling the brine, returning again to the compressor. Cold brine is pumped to the jacket of the kettle, where it abstracts the heat from the reaction, and is then returned to the brine tank. Needless to say one brine tank can be used for a number of nitrating kettles.

In some plants, where exhaust steam and plenty of cooling water is available, the absorption type of refrigerating machine is often advantageously employed.

An Example of Acetylation Apparatus

Acetylation may be carried on in aluminium, silver or silver-lined apparatus. Fig. 11 shows a typical example of an acetylation apparatus which is especially designed for the acetylation of aniline oil in the manufacture of acetanilid. The kettle itself is made of sheet aluminium, with all the joints welded. Surrounding the kettle is an iron jacket, which is set in a furnace fired preferably by gas, but conveniently by either oil or coal, the iron jacket forming an air bath for the kettle. These kettles are also heated by circulating oil, as sulfonating kettles are sometimes heated, but on

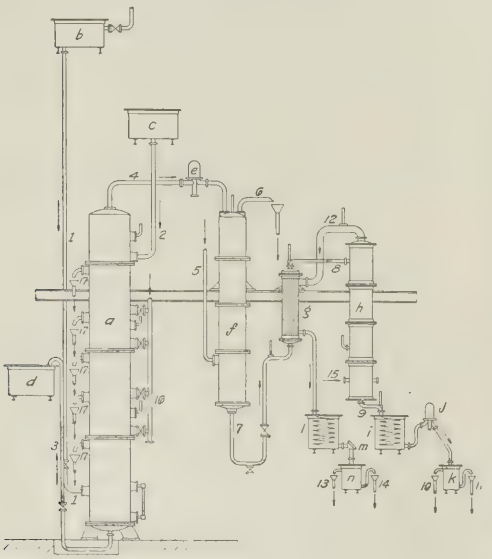

FIG. 8—COMPLETE CONTINUOUS NITRATION APPARATUS

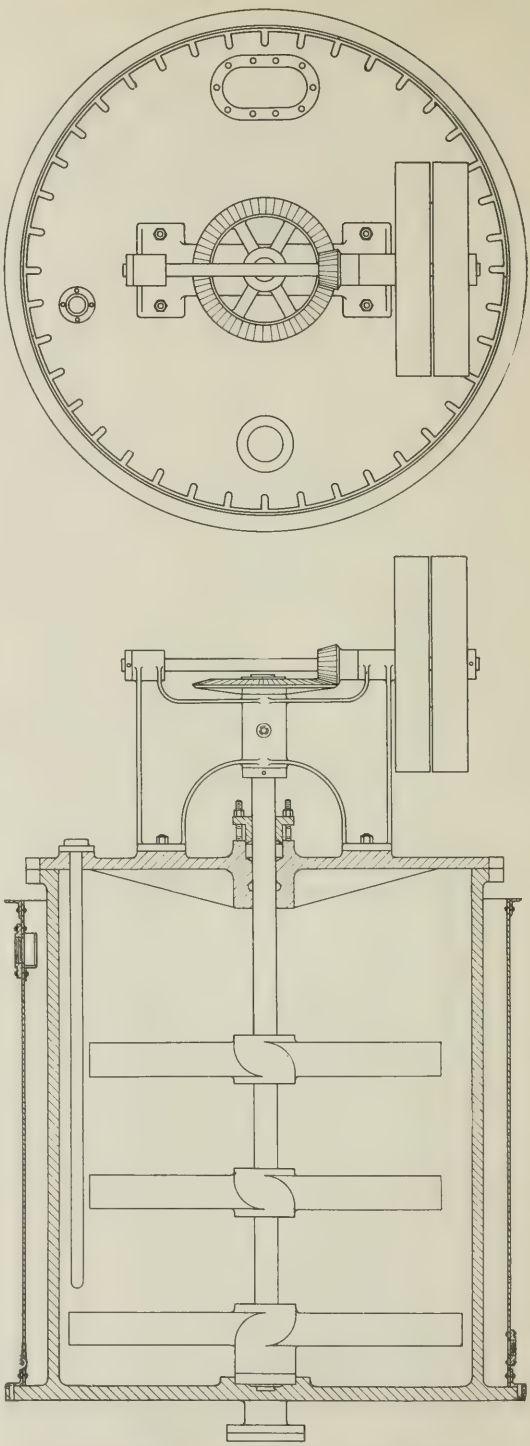

FIG. 9—STIRRING DEVICE FOR USING SOLID NITRATES

account of the high temperature necessary at the end of the operation, the oil circulating method of heating is sometimes troublesome. When heating is accomplished by circulating oil, bottom discharge may be used, but it is fully as convenient to discharge the kettle by means of air pressure through a pipe extending to the bottom, as shown in the drawing.

The kettle is equipped with reflux condenser. This may be the boiling head type, as shown, or it may be a column with Raschig rings, one filled with glass marbles, or simply baffle plates. The use of a boiling deck or a Raschig ring column permits the use of a weaker acid for acetylation.

Connecting to this column is a silver tube

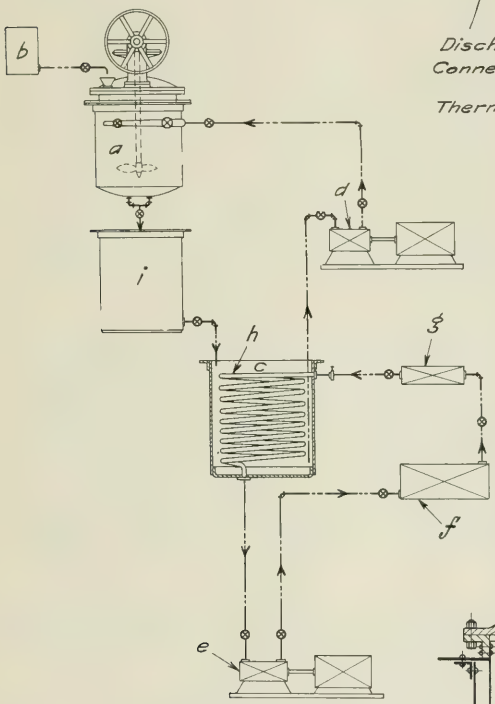

FIG. 10—ARRANGEMENT FOR BRINE COOLING

condenser so arranged that it may be used as a reflux to return the condensate to the kettle, or as a condenser discharging into a receiver. This is managed by the valves marked *a* and *b*. The valves may be earthenware cocks, silver cocks, or a gate valve, very heavily silver-plated. In practice, it is an excellent precaution, in case a silver-plated gate valve is used, to have the plating done twice. A watch glass, marked *c*, is provided at the end of the condenser, so that the operation of the apparatus shall be evident to the operator. The kettle is provided with a silver thermometer tube extending well to the bottom. A recording thermometer should be provided.

The cover, which is bolted securely to the kettle and made tight with an asbestos or silver gasket,

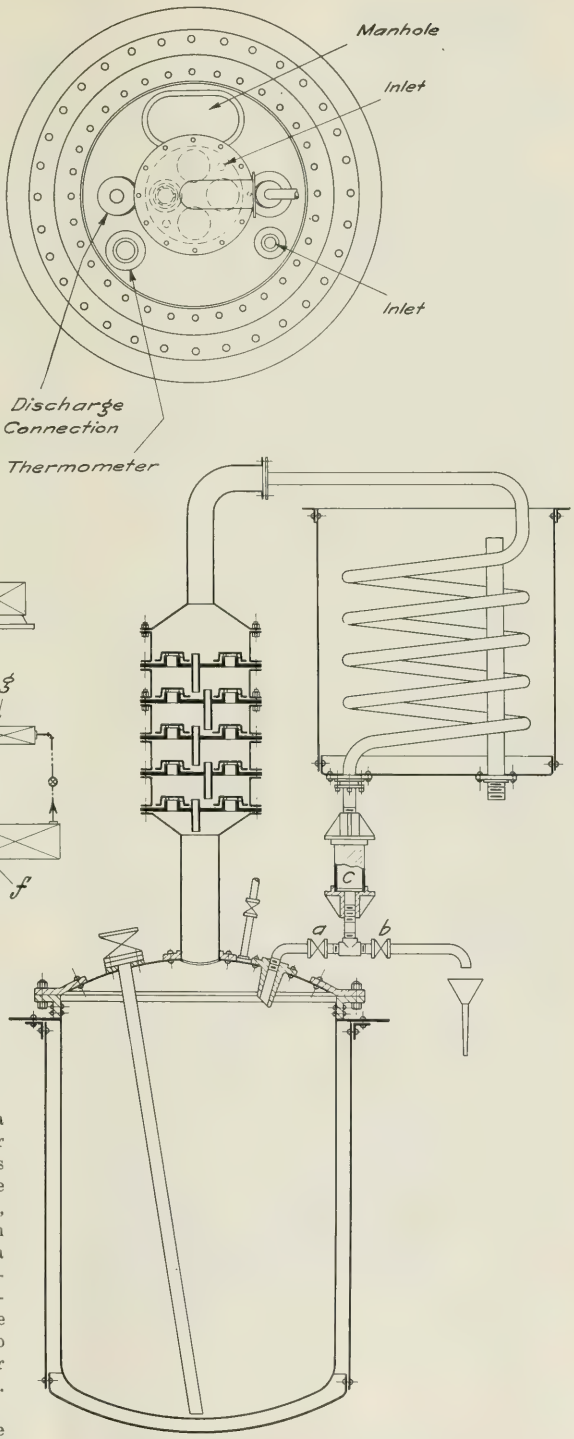

FIG. 11—ACETYLATION APPARATUS

is provided with a manhole, an opening for acetic acid, a separate opening for anilin oil, a separate opening for introducing air to discharge the kettle, an opening for the returns from the condenser, and an opening connecting with the discharge pipe extending to the bottom of the kettle. All these openings must be provided with either silver cocks or silver-plated gate valves.

A very pure sheet aluminium must be used for the kettle, and the joints must be carefully welded. Aluminium solder is entirely inadmissible in any part of the apparatus. The cover is made of sheet aluminium, riveted to a cast aluminium ring, which is in turn bolted to a cast aluminium ring, which is riveted to the kettle.

The boiling head may be made of sheet aluminium. In case boiling decks are used, the decks may be cast aluminium. In case Raschig rings are used, they may be of earthenware, aluminium or silver, and may be contained in a sheet aluminium boiling head. Satisfactory results are obtained from an apparatus such as described when used for the manufacture of acetanilid.

Oxide of Zinc*

By George C. Stone.

The method of making oxide of zinc direct from the ore was invented and developed at the works of The New Jersey Zinc Co. at Newark in the middle of the last century. The process was invented by Burrows, who had not the ability, financial or technical, to work out the details necessary to make it of commercial value. This was done by Colonel Wetherill, whose name is commonly attached to this process. The grate bars used are also frequently called Wetherill grates, which is a misnomer because they were in common use for boiler firing at the time and he never claimed their invention.

The invention of the process was due to the efforts of The New Jersey Zinc Co. to find a profitable means of working the ores from Franklin and Sterling Hill, N. J. These are a mixture of franklinite, willemite and zincite, containing about 20 per cent of zinc. The first attempts were to make spelter, which were not successful, owing to the low grade of the ore and the fusibility of the residue. Failing in this, the next attempt was to make oxide in large muffles and reverberatory furnaces. This succeeded, although the cost of operation was high, the recovery low, and the quality of the product uncertain. In 1855, the new process was patented and has been in successful operation ever since its introduction.

Essentially, the process is to spread a mixture of coal and ore on a body of burning coal on a perforated grate and blow an excess of air through the grate. The zinc is reduced in contact with the coal, volatilized and burned by the excess of air in the upper part of the furnace and in the flues. It is then carried to the bag rooms by the excess air and products of combustion which are forced through the flues by fans. In its main features, the process is the same to-day as at the time of its invention, but the details have been so modified that it would hardly be recognized by its originators.

*A paper to be presented at the St. Louis meeting of the American Institute of Mining Engineers, October, 1917.

ORES

The process is applicable to all the oxidized ores of zinc and to roasted sulphides, provided the gangue is not so fusible as to leave a residue that is impervious to the blast. In many cases the ores contain impurities that make it impossible to produce an oxide of a good enough color to be available as a pigment. These impurities are any volatile metals that form colored oxides or sulphides. Cadmium is one of the worst, because it is very volatile and its dark brown oxide and bright yellow sulphide both have strong tinctorial powers, so that small fractions of a per cent seriously injure the color of the oxide. Lead, which is one of the commonest impurities in zinc ores, also injures the color, though to a much less degree, as it usually forms basic sulphates which are nearly white. On other accounts lead is often objectionable, particularly when the oxide is to be used for the manufacture of rubber goods. Sulphur may occur in oxide as sulphides, sulphates or as sulphurous anhydrides, the first and last of which are objectionable; the first on account of probable injury to the color, while the last is believed by many paint manufacturers to have a bad effect on the grinding properties. Opinion on the latter point is by no means unanimous. Sulphates, if soluble, have very objectionable qualities for outside paints, as they leach out of the paint-coat, leaving discolored spots. Chlorides, in appreciable quantity, are rare, but if present would be open to the same objection.

FUEL

The fuel used must be one that does not give a black smoke, which would ruin the color of the oxide. Anthracite is the most satisfactory fuel for the purpose and the one generally used. In the West, where anthracite is expensive, semi-bituminous coals, low in volatile qualities, are sometimes substituted for it in whole or in part, but they are never as good. Coke alone does not work well, as it causes a very intense local heat that makes the residue impervious to the blast. It is occasionally used as a part of the charge fuel.

FLUXES

With siliceous ores, limestone is sometimes added, but in general it does more harm than good, owing to its tendency to make the residue too fusible.

PREPARATION OF CHARGE

The ores and coal are usually received at the works in fine enough condition for use without further crushing. Nearly all the ores are either concentrates or roasted products and are inevitably finer than is necessary. As the small sizes of coal are suitable for the purpose, and are cheaper than the large, they are invariably used. If fluxes are used they are crushed to about the size of the ore and coal. There should not be a great difference in the size of the different materials, or it will be impossible to mix them properly.

PALMERTON PLANTS

The Palmerton plants of The New Jersey Zinc Co. (of Pennsylvania) are the largest and best equipped oxide plants in the world.

Fig. 1 shows the general arrangement of the West plant and Fig. 2 that of the East. They are similar, but the East plant has fewer and larger bag rooms and

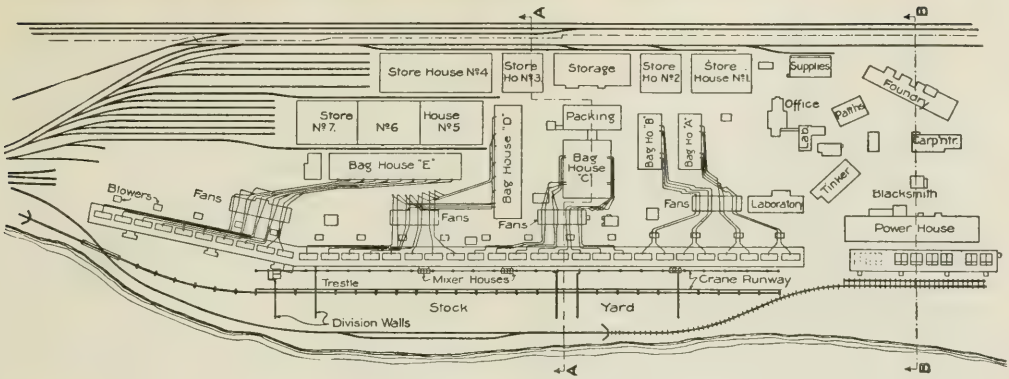

FIG. 1—PLAN OF WEST PLANT

differs somewhat in details. At both plants the raw materials are delivered on the trestle at the south of the plant and are either placed in bins or stocked in piles. The ore and coal are taken from the bins to the mix-house by larries. The mixed charges are delivered to the bins above the furnaces and distributed by traveling cranes. Each block of furnaces is a separate unit, having its own blower, exhaust fan and bag room. The oxide is trucked from the bag rooms to the packing room and the final packages skidded or trucked to the storehouses.

STOCKING AND MIXING—EAST PLANT

The ore and coal are delivered on the double track, steel and concrete trestle, 22 ft. high with Brown tangential bins below the track next to the furnace room. Materials for current use are dumped directly into the bins and the surplus is stocked back of the trestle by a bridge crane of 233 ft. 9 in. span equipped with a 10-ton Brown grab-bucket. This equipment also returns materials from the stock piles to the bins when necessary. The charges are drawn from the bins to a weighing larry which has two hoppers, each containing a furnace charge. These are carried to Ransome concrete mixers placed at one end of the furnace room. The mixed charges are elevated by a pair of counterbalanced skips to bins above the furnaces. From the bins the mixed charge is taken to the furnaces by cranes each having three hoppers holding one-third of a furnace charge each. Each hopper is placed on a scale so that the charge is equally divided between the three.

STOCKING AND MIXING—WEST PLANT

All materials are delivered on a single track steel and concrete trestle 47 ft. high, down the center of the storage yard. The materials are taken from this by a bridge crane of 48 ft. 8½ in. span with a 2-yd. bucket and placed in elevated bins next the furnace room. The ore and coal are stocked and reclaimed by the traveling bridge and by locomotive cranes on the high trestle. The total storage capacity is 200,000 tons of ore and 175,000 tons of coal. The fuel and the various ores are taken by bridge cranes to small bins placed over the mixers. The materials are dropped from these bins into weighing hoppers and from these into the Ransome mixers. The mixed charges are elevated to bins over the furnaces and then distributed by cranes much as at the East plant, except that there are no scales on the cranes or larries. This arrangement of

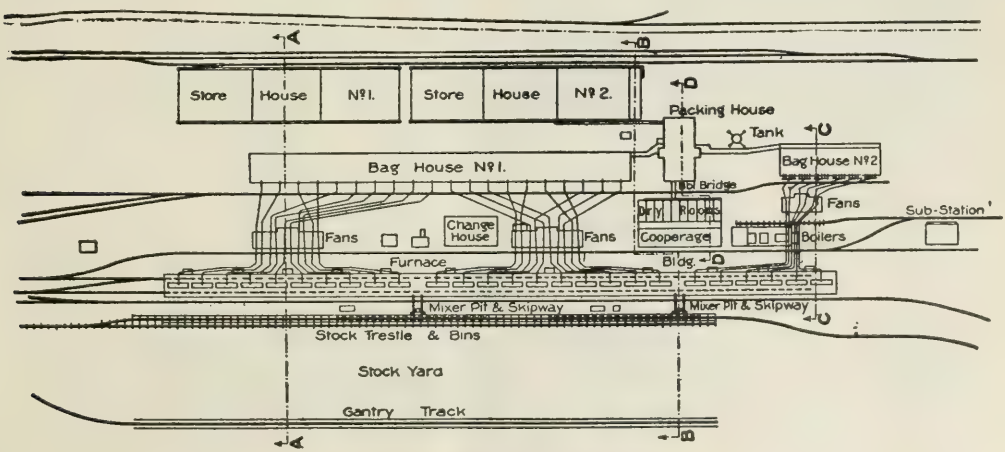

FIG. 2—PLAN OF EAST PLANT

doing all of the weighing at the mixer on a fixed hopper is more satisfactory than weighing larries, because the latter are very difficult to keep in adjustment.

FURNACE ROOMS

The furnace rooms at the two plants are quite similar, the main differences are that at the West plant the furnaces are carried on a concrete foundation and at the East plant on the floor. In both cases the furnaces are elevated sufficiently to allow the residue to be dropped into hoppers below the floor and then into cars. The framing of the buildings is quite different, the East plant (the later one) being arranged to give more room for the charge cranes. The West plant furnace room contains 34 blocks of furnaces and the East plant 26. All the blocks are alike, consisting of four furnaces 19 ft. 6½ in. by 5 ft. 11½ in. (Fig. 5). Each furnace has independent blast and flue connections and three charge openings in the roof surmounted by hoppers. Each furnace works three charges in 24 hr. The different furnaces of the block are charged alternately at 2-hr. intervals in regular order. Charging in this way, there is always one furnace starting, one nearly finishing and two working strongly, and the volume and temperatures of the gases to be handled are nearly uniform at all times.

FURNACE OPERATION

When the furnace is worked off the dampers in the flues are closed, cutting it off from the bag room. The blast is shut off and the working doors taken down. Three men work on the furnace at once, each having a separate door. The loose material on top of the charge is raked off and dropped on the floor close to the furnace. The clinker is then broken up by heavy slice bars and raked into hoppers under the floor. The furnacemen then thoroughly clean the side and back walls from any clinker that has fused to them. When all of the old charge has been removed and the furnace cleaned, the grate is covered as rapidly as possible with a thin layer of coal, the doors closed and a light blast turned on. The coal is lighted by the radiation from the hot arch and it is important that it should light quickly and evenly. When the bed coal is burning brightly, the charge from the hopper is dropped up on it and leveled. The doors are now closed, the blast turned on and the furnace left to itself with occasional inspection to stop any blow holes that may form. With the large charges that are now worked, it is considerable time before any zinc vapor appears. When it does, the dampers in the flues are reversed, sending the gases and oxide to the bag room.

FANS AND PIPING

The blowers for the oxide furnaces are direct-connected to motors, the wheels of the blower being placed on extensions of the motor shaft. They are located in small houses outside the furnace room, two in each house.

Each furnace has two outlet pipes, usually 20 to 22 in. in diameter which lead up to the drum pipe overhead. The drum has an outlet in the middle of its length leading to the exhaust fans. Formerly the gases passed through a brick settling tower between the furnaces and exhaust fan, but this is now usually omitted as unnecessary. The exhaust fans are extra heavy plate fans with special Hyatt roller bearings and water-cooled shafts, belted to motors. Aside from the shafts, bearings and extra thickness of plate, they are of the ordinary types. For convenience in attendance, a number are placed in one building. The West plant has four fan rooms, three containing eight fans each and one containing ten fans. At the East plant there are two with ten fans each and one with six. From the exhaust fans to the bag rooms, in each case, run round pipes 3 ft. in diameter, made of No. 16 sheet iron and provided with numerous clean-out openings. In all cases, the pipes are arranged to give as nearly as possible the same length from furnaces to bag rooms. This is done partly to equalize the friction in the different lines, but mainly to secure proper cooling of the gases before reaching the bag room.

BAG ROOMS

The method of collecting oxide in bags was first patented by S. T. Jones in 1852 and has been patented by others many times since. The bag rooms at Palmerton vary considerably in size; the first two built hold-

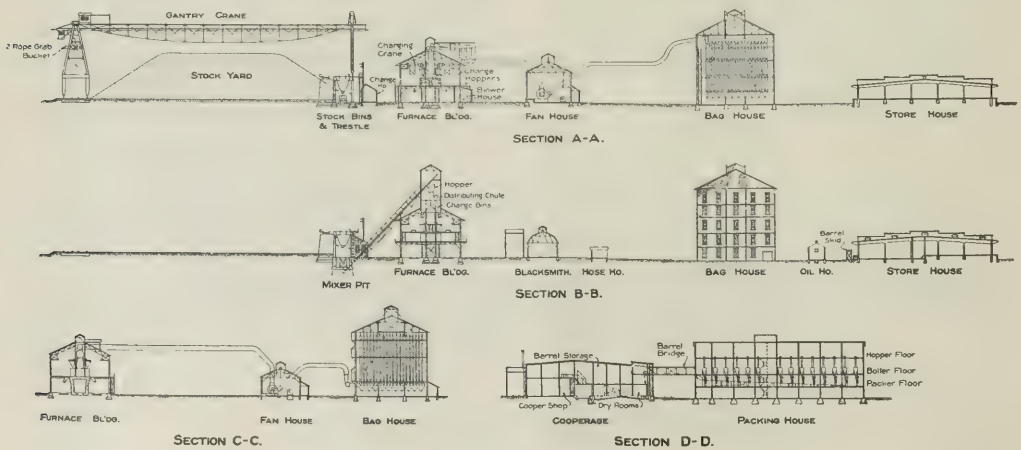

FIG. 3—SECTIONS OF EAST PLANT

ing bags enough for four blocks, while the latest contains the bags for twenty. The larger rooms are more economical in labor and do not cause any inconvenience, provided the ventilation is equally efficient. The bags used are all of heavy, closely woven cotton sheeting 22 in. in diameter and about 40 ft. long In the majority of cases the gases enter a header at the top of the room and from there pass to a series of parallel pipes from the bottom of which the bags are connected to hoppers, four bags to each, with a single collecting bag tied to an outlet at the bottom of each hopper. At intervals the gases are shut off from the two lines of pipe connecting with a single line of hoppers and the bags shaken. This pair of pipes is again connected to the main header and the next two lines shut off and shaken. The frequency with which the bags are shaken depends upon the relative area of grate and bags, and the amount and quality of the oxide being made. The proper ratio of grate surface to bag surface has been a subject of much discussion. It varies in practice between 1:80 and 1:130. The amount actually necessary depends mainly on the efficiency of the ventilation of the buildings and the frequency of shaking. A well-ventilated room will consume no more muslin with a ratio of 1:80 than a poorly ventilated one with a ratio of 1:130. Recent experiments indicate the probability that a well-ventilated bag room with a mechanical shaker operating at short intervals will allow of a very great reduction in the necessary bag area.

The collecting bags are removed from the hoppers every 24 hr., or oftener if necessary, and taken to the packing room. This is done by a trucking gang that removes the filled bags and replaces them with fresh ones, trucking them by hand to one side of the bag room, where they are coupled together and the train drawn to the packing room by a motor.

PACKING

The packing room is a four-story building of mill construction. The trucks are hauled into the ground floor and then taken one by one on a platform elevator to the upper floor. There are a number of openings in this floor leading to bolters on the floor below. Around each opening is a wide shelf on which the bags are rested while their contents are emptied into the bolters. The third floor contains nothing but the bolters, and a room for sewing and making bags. The bolters used are of the ordinary types used in flour mills. The packing machines are arranged in four lines on the second floor. They are also of a type largely used for flour. There is usually one packer below each bolter and fed directly by it. In some cases, owing to the lack of room, one bolter feeds two packers. The oxide is packed partly in paper bags holding 50 lb. each, partly in barrels with 30-in. staves and 19⅛-in. heads holding 300 lb. each, while export material is packed in special barrels and weights to suit the different markets.

The barrels are kept in a storage room where the hoops are driven by a machine and then nailed by a second one, and from here they are passed to the packers. All barrels are weighed empty and filled, the weights adjusted and the barrels headed. They are passed to the ends of the building and rolled on skids to the storehouses. The second floor of the packing room is high enough above the ground level to allow sufficient slope to the skids to carry the barrels to all but the most distant store houses. The paper bags are loaded on trucks and taken to the storehouses on the same skidways.

COOPERAGE

The cooperage is at the East plant, next the packing room. It is fully equipped with machinery and can manufacture about 2000 barrels a day. The barrels are delivered directly from it to the East plant packing room and by special railroad cars to the West plant storehouse.

The storehouses are all one-story mill-construction buildings with the floor elevated to the level of a box car. Each has doors and platforms on opposite sides, one for receiving material from the packing room and the other for loading cars.

POWER PLANT

Power for both plants is supplied from a central station at the West plant between the oxide and the spiegel furnaces. The boiler room is equipped with Edgemoor boilers of 536 hp. each, which can be fired with coal or with the waste gases of the spiegel fur-

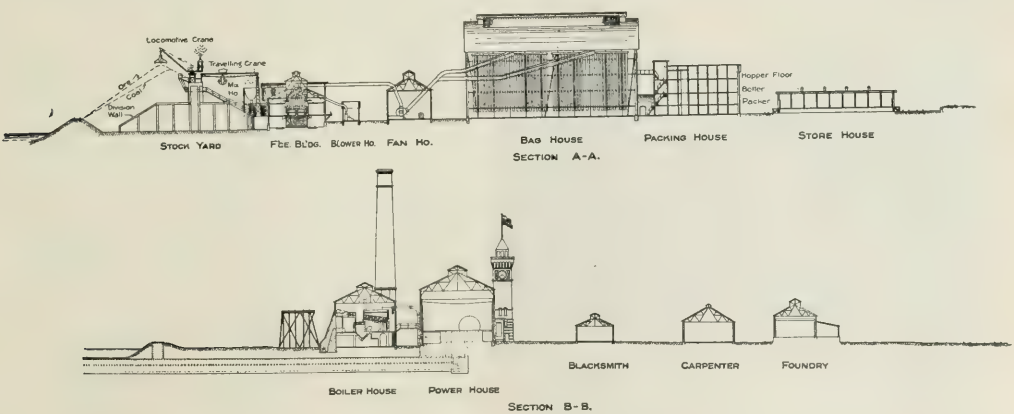

FIG. 4—SECTIONS OF WEST PLANT

naces. The engine room parallels the boiler room and is located about twenty feet north of it. It contains three horizontal cross-compound blowing engines for the spiegel furnace; four direct-current generators, two of 500 and two of 600 kw., each direct-connected to a horizontal cross-compound Corliss engine; three Allis-Chalmers turbo-generators, two of 2000 and one of 4000 kilowatts, 6600 volts, three phase; two motor-generator sets used as a reserve for both alternating- and direct-current lines, as either part can be used as a motor to generate current of the other kind, if needed. In addition, the engine room contains the exciters, condensers and pumps. The engine room is entirely above ground, giving a light basement for the pipes and elevating the machinery above danger from floods. This also permits a railroad track to enter at the ground level, so that new machinery or repair parts can be brought into the building, and there lifted from the cars and put in place by a traveling crane that covers the entire space and can lift the heaviest piece of any of the machines. The switchboards are in a tower at the north side of the building, where they are visible from all parts of the generator floor, but do not project into the room. The tower gives ample room for leads and anchorages of cables.

ORES

The ores used at Palmerton are almost entirely concentrates from the company's mines at Franklin Furnace and at Sterling Hill, N. J. Three of these products are smelted for oxide: franklinite, half/half and dust. The composition of these is about as follows:

	Franklinite	Half/half	Dust
Zn	18.2	18.4	17.6
Fe	35.0	15.2	20.1
Mn	12.8	12.2	8.9
SiO_2	3.6	12.6	7.2

The franklinite is worked by itself and the residue smelted in blast furnaces for the production of spiegel. The half/half and dust are mixed and the residue wasted, as it contains too little Fe and Mn and too much SiO_2 to be a profitable smelting material.

Franklinite is the easiest of these ores to work and gives the best product. The half/half and fines are mixed and worked together. The charges per furnace average:

	Ore	Coal
Franklinite	2.62T	1.62T
Half/half and fines	1.95	1.36

The recovery for franklinite averages about 86 per cent and for the half/half and fines charge about 78 per cent. Both charges and recoveries vary somewhat with changes in the ore and quality of the oxide desired. The recovery and quality of product are controlled by the selection of the ores, ratio between ore and coal and of both to the grate surface, and what is of great importance, the balance of blast and exhaust and the proper proportioning of both to the charge being worked. Where leaded ores are worked the charges and recoveries vary much more and average figures are of little value. In general, with such ores the charges are a little lighter and the recoveries lower than for the New Jersey ores. The recoveries of lead are usually rather better than of zinc, roughly as 9 to 8. For estimating purposes the make of oxide is generally

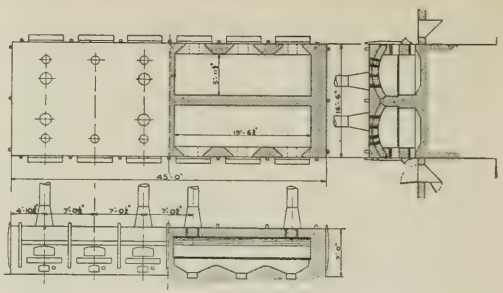

FIG. 5—FURNACES

taken as equalling the combined Zn + Pb in the ore, the gain in O and SO_3 about balancing the losses in Zn and Pb.

PRODUCT

The product is divided into five grades, two for the use of paint manufacturers, two for rubber and an off-grade that is reworked either for oxide or spelter. For the paint trade, the grading is entirely by color, samples being daily rubbed down with oil and compared with standards. For the rubber trade, slight variations in color do not make so much difference and the grading in this respect is not so close, but freedom from lead and absence of small hard particles is insisted upon.

The variation in composition of the different grades is very slight, the range of composition of all being nearly the same. The material as shipped uniformly contains 99 per cent or over ZnO, the principal impurities being: SO_3, 0.25 to 0.33 per cent; H_2O, 0.10 to 0.50 per cent, and PbO, 0.05 to 0.30 per cent.

The principal use of zinc oxide is as a paint pigment and for this purpose its purity of color and freedom from discoloration by gases and atmospheric conditions, fineness and uniformity make it particularly useful. As a pigment it has the disadvantage of slow drying and a tendency to become unduly hard in time. The general consensus of opinion among paint manufacturers now is that a mixture of pigments is better than any single one. In these mixtures, zinc oxide is an almost invariable constituent because it prevents chalking and gives a surface that retains its color.

Next in importance is its use in rubber goods. In the manufacture of such products, zinc oxide is used for two purposes. It is used as a pigment to produce white goods, and is excellent for this, provided it is substantially free from lead. If this were the only effect it had it might be replaced by cheaper materials, but it also greatly increases the tensile strength of the resulting material. A mixture of pure rubber and sulphur vulcanized has a tensile strength of about 2000 lb. per square foot and an elongation of 960 per cent of its original length. The effect of adding zinc oxide is to increase the tensile strength but diminish the elongation as shown in Table 1.

TABLE I

Per Cent ZnO	Tensile Lb. per Sq. In.	Elongation, Per Cent
25	2,400	720
35	2,400	700
45	2,700	680
55	2,500	620
65	2,000	540
75	1,300	400

It will be seen that up to about 60 per cent, ZnO increases the tensile strength of rubber. No other material tested has this effect.

As the supply of lead-free ores is limited and the demand for ZnO is increasing, much more leaded oxide is being made. The process is the same but the charges are usually lighter and the recoveries lower. In most cases the furnaces used are double ended with one or two working doors at each of the opposite ends. This makes the furnace easier to clean, as there is no back wall, which is the most difficult part from which to cut accretions. On the other hand, this type of furnace cools off more when charging and does not, as a rule, light up as quickly. Which type is better is still an open question, the users of each claiming that theirs is superior. In making leaded oxide, it is customary to have a brick combustion chamber over, or close to, the furnace. This insures a sufficient time of contact at a proper temperature to cause the lead to be converted into basic sulphate. This is essential, as all of the oxides of lead are strongly colored and injure the color of the product, while the basic sulphate is very nearly white and does not have this effect. In many cases the bag rooms of the works making leaded oxide have no overhead distributing pipes, the hoppers being connected and used for this purpose.

Leaded oxide is divided into several grades, depending on the amount of lead it contains. This is always stated as the amount of neutral sulphate ($PbSO_4$) equivalent to the total lead present, although it is always present mainly as a basic sulphate. It forms an excellent material for the manufacture of mixed paints. So far this grade has not proved satisfactory to the rubber manufacturers.

PRODUCTION

It is impossible to give production of oxide of zinc, as the statistics are not published by the Government. Such figures as have been published are not comparable, because the grouping of the different products is not always the same. The increase has been very rapid, especially within the last three or four years.

New York City.

Club for American College Men in Paris.—The establishment in Paris of a home club for American college men or their friends who may be in the French capital for military or other service in the cause of the allies is contemplated by the American University Union in Europe, which has just been organized in this country. The privileges of the club will include information bureau, writing and newspaper room, library, dining room, bedrooms, baths, social features, medical advice, etc. The union also expects to provide headquarters for the various bureaus already established or to be established in France by representative American universities, colleges, and technical schools. It will cooperate with these bureaus when established, and in their absence to aid institutions, parents, or friends in securing information about college men in all forms of war service, reporting on casualties, visiting the sick and wounded, etc.

The University Union will have its headquarters in Paris with branch agencies in London and such other cities in allied countries as may seem desirable. Its office in America will be in or near New York City.

The Production of Salt in Szechuen Province, Western China—III

By H. K. Richardson

THE WELLS OF KWEI-CHOW FU

In two former articles* the medium and deep salt wells of the province of Szechuen were described. This article will deal with the shallow wells, most particularly those at Kwei-Chow Fu.

Kwei-Chow Fu is situated on the Yangstze River just over the border in the Province of Szechuen as one travels up the river (see map in first article). The wells in question are situated 5 miles east of the town on both banks of the river. Those on the southern side are small and of little importance; the most important producer is a single well on the northern bank of the river. This well only operates a few months a year, for it is dug on the shingle bank of the river that is under water at the high stage of the river. When the river recedes in October the well is dug out and work continues night and day, no stopping on Sunday, until the spring freshets in April inundate the bank carrying stone and gravel into the well hole and filling it up. The sides of the well are made of permanent stonework, so that all that is needed the next season is to locate the well and clear out the débris and make a few repairs to the retaining wall. Fig. 1 shows the situation of the well on the river bank, surrounded by the shacks in which the workers live during the season. The evaporators are all nearby the well, so there is always steam arising from the settlement, while by night the light of the many fires makes one think of a small steel village.

The well is an open pit some 35 ft. deep and about the same in diameter. The well or spring itself is enclosed by a stone facing 12 by 12 ft., which also serves as the landing stage from which the brine is dipped into the coolies' buckets. Fig. 2 shows a general view of the well. Access to the bottom is obtained by three flights of stairs made of stone and worn smooth by many years of use.

All the brine is carried to the top in buckets by coolies. Figs. 3 and 4 show the coolies lined up to fill their loads. Fig. 3 was taken when brine was plentiful, so no one was afraid of not getting his share, while Fig.

*This Journal, Jan. 1, 1917, and Sept. 1, 1917.

FIG. 2—BOTTOM OF WELL. GENERAL VIEW, SHOWING RETAINING WALL AND FLIGHT OF STEPS. COOLIES CARRYING BRINE UP STEPS. LANTERN SLUNG ACROSS FOR NIGHT WORK

4 was taken at a time when brine was scarce and everyone was after more than his share. In the latter photo about a dozen naked men were down in the well scooping up the brine with a bucket and filling those of the coolies. The brine when brought to the top of the well is dumped into a half-barrel containing pebbles; the brine overflows from this head tank into wooden sluiceways 5 in. wide by 3 in. deep, and finds its way to the evaporators. Fig. 5 shows the edge of the head tank

FIG. 4—BRINE SCARCE—EVERYONE BUSY AS BEES TO GET HIS SHARE. NOTE BUCKETS ON CARRYING POLES

and the sluiceways. Each evaporating unit consists of a storage pond, two filters and three evaporating pans and their furnaces. The brine coming along the main sluiceway is shunted to the respective ponds by a valve of hard clay balls. The storage pond is made by hollowing out a depression in the hard clay and hammering the clay solid. Sometimes lime is added to the surface of the clay. These ponds are 20 ft. long, 12 ft. wide and 2 ft. deep.

The brine from the storage pond is dipped into two filtering barrels, these barrels being filled with clay balls about 2 in. in diameter. Some of these balls are in reality salt brick. In seasons of plentiful supply of brine some of the brine is poured out over the clay surrounding the chimney of the furnace and all the water evaporated off. This process is repeated until the clay is saturated with salt and becomes very hard when it is broken up into the clay balls above mentioned. Fig. 6 shows one of these chimneys. These clay balls are then stored against the time when the well fills, and there is a little interval that the pans can be worked before they are flooded. They also serve as the filtering material, cleaning out the dirt and also leaching out their contained salt, thereby increasing the degree of saturation of the brine and increasing the fuel economy. Their use is apparently unique in this well, and is a fine illustration of efficiency of operation and ingenuity in making the best of a situation.

The clear brine is piped from the filters to the first evaporating pan, into which it drips constantly. Here it is concentrated until salt appears around the edges, when it is dipped over into either of the other two pans. From these two pans the crystals are constantly

FIG. 3—BRINE PLENTIFUL—WATCHING THE FOREIGNER MORE THAN THEIR JOB

FIG. 5—HEAD TANK TO SLUICEWAYS. GRAVITY FEED TO STORAGE TANK AT EVAPORATING PANS

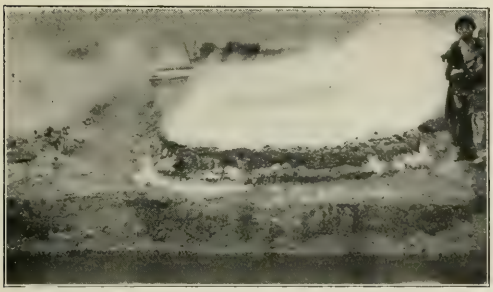

FIG. 6—CLEANING OF PANS. MAKING SALT BRICKS

collected and allowed to drain in a V-shaped wooden trough. Fig. 7 shows a top of a pan and the crystal drainer. When the layer of salt formed on the bottom of the pan slows up the evaporation too much the brine is allowed to evaporate to dryness and the hard salt cake is removed and sold for distant traffic.

Each pan is set over its own furnace, which is very simple in construction; a hole 6 ft. in diameter and 7 ft. high is dug in the ground and lined on three sides with pounded clay, the front or fire side being closed up with mud brick or stones. The furnace is carried up 4 or 5 ft. above ground and tapered in to receive an iron pan 3 or 4 ft. in diameter. The pan is made of cast iron ⅛ in. thick and is 9 to 12 in. deep in the middle. This pan is carefully luted on the top of the furnace, so that all smoke must pass out of the holes at the back of the furnace and up through the chimney described above. Fig. 8 shows the fire side of one of these furnaces. The fire bed is about 8 ft. below the bottom of the pan, allowing of complete combustion of the fuel.

The fuel used in these furnaces is a slack coal mixed with mud to make briquettes. The coal of this region is mined several miles up a small stream and floated down in small boats. Since the coal is very friable there is much small material; this fine stuff is mixed with considerable amounts of clay and made into briquettes 3 by 2 by 5 in., which are sun dried and then used. They make a good fire that burns slowly and evenly. Their most important objection is the amount of sulphur dioxide given off. Fig. 9 shows one of the numerous briquette factories, or rather yards, on the beach. A careful look at the picture will disclose the entire mixing and molding outfit.

The operations of the plant are best seen from the following flow sheet:

The well is the property of 100 families, who share the ownership of the well on the community idea, and all others must keep out. Each family erects its own straw hut on their section of the beach at the beginning of the year's season and the whole family helps in the work, living on the spot. Each family sections off its pans, storage ponds and hut from the others. Each family does its share in cleaning out the well at the beginning of the season, and must share in the building of the sluiceways to its pans. There is no charge made for the brine, each family hires the number of coolies it needs to supply its pans and then they have regular shifts for the day and night work. Each family is entitled to the use of four evaporating pans, however

FIG. 7—EVAPORATING PANS AND STRAINERS

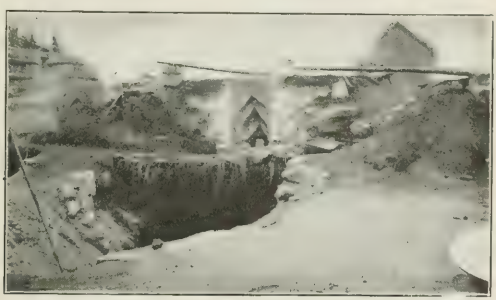

FIG. 8—FIRE SIDE OF FURNACE—CHARGING DOOR FOR COAL

the average per family is only three, making about 300 pans in operation.

The brine obtained from the well is very weak; the owner of one of the pans told us that he recovered only 6 to 8 oz. per load of brine; this would mean about a 0.4 per cent solution of sodium chloride. He also stated that he produced 120 or 110 or 100 catties of salt per day and night per pan, depending on how long the pan had been run and how thick the pan scale became. When they only produced 100 catties the pan scale was removed and the pan started over again. The average yield per three pans per day was 340 catties or 453 lb. of salt ready for the market. This same man gave us the figures of 2133 lb. of coal used per 133 lb. of salt produced. This would give 15.6 lb. of water evaporated per pound of coal; this would be too high if only the weak brine is considered, but since bricks are extracted and the brine strengthened this figure is unreliable for calculating the evaporation of water.

The balance sheet of this operator is of interest.

INCOME PER MONTH		
13,600 lb. of salt at 2c per lb		$272.00
EXPENDITURES PER MONTH		
Labor—6 brine carriers at $2.00 per month	$12.00	
—3 furnace men at $4.00 per month	12.00	
Food for the above nine men	7.20	
		$31.20
Coal—108.8 tons at $0.87 per ton		94.66
Salt tax at 1/2c per lb		68.00
Depreciation of pans and repairs:		
Cost of furnace	$13.00	
Cost of furnace pans	3.00	
	$16.00	
In use for 7 months then furnace total loss, pans salable for other purposes at low price so assume a total loss		2.29
		$196.15
Monthly profit		75.85

Out of the above profit we can justly deduct the slight cost of marketing the salt, the cost of erecting the buildings each year, the annual cleaning out of the well, and the erecting and taking down of the sluiceways, etc., each year. These all told should not exceed $50 in a season, so with a gross profit of 7 × $75.85, or $530.95, there is still a net profit of $480.95 per season. This is a princely sum for a Chinese family, and does much to explain the care with which the family watches the work. It is very probable that considerable graft or "squeeze" money was paid to officials from the net profits. There is practically no permanent investment, since the pans and furnaces are used only seven months a year and then lost under the rising waters of the river.

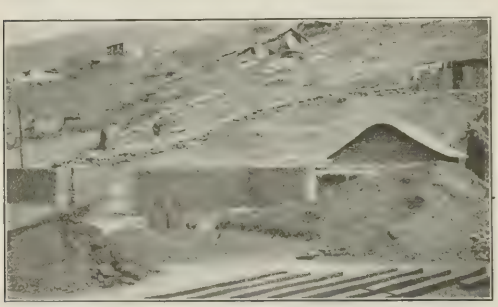

FIG. 9—BRIQUETTE YARD ON RIVER BANK AT KWEI CHOW FU

There are two other shallow wells that supply a much larger amount of salt than that at Kwei Chow Fu. These are the wells at Yun Yang Chang and Da Ning Chang. As far as I know these have been visited by only one white man, Rev. Mr. Hannah of the China Inland Mission of Kwei Chow Fu. The following data was given to the writer by Mr. Hannah:

WELLS AT YUN YANG CHANG, 7 MILES NORTHWEST OF YUN YANG HSIEN

The wells are about 10 to 20 ft. in diameter, walled with stone down as far as can be seen. They vary in depth from 100 to 200 ft. The brine is raised in small buckets holding 2 gals. Two buckets are attached to the end of a rope, the rope thrown over a sheave so that when an empty bucket descends to the well a full bucket ascends. At the large wells there are twenty to thirty of these windlass lifts arranged around the periphery of the wells; they are manned by coolies stripped to the waist. Each coolie has a rope around his waist to prevent him from falling into the well. The brine evidently comes from an underground spring and is very clear, needing no filtration. Coal from an adjoining hillside is used to evaporate the brine.

WELLS AT DA NING CHANG, 10 MILES FROM DA NING HSIEN

The brine at this place is obtained from a spring on a hillside. The spring is a hole about 4 ft. in diameter; the brine flows from the spring by gravity directly into a large concrete (Chinese style) reservoir. From the reservoir bamboo tubes lead the brine directly to the evaporating pans situated on the hillside at a lower level. The brine is allowed to run continuously into the pans. The brine is clear and needs no filtration. Coal is used as at Kwei-Chow Fu for the evaporation.

The relative productions of the various classes of wells is obtainable from data collected by Sir A. Hosie in 1904. The data given below is from his compilation for 1902 or 1903:

Type of Salt Well—Situation		Production Catties (1.33 lb.)
Deep wells, 3000 ft. over:		
Tzu Liu Tsing		274,000,000
Medium wells, about 1000 ft.:		
Ch'en Wei Hsien and Kiating Fu	141,100,000	
Tai Ho Chen district	2,700,000	
Chien Chow district	7,300,000	
Unclassified, mostly medium wells	5,000,000	
Total		156,100,000
Shallow wells, 200 ft. and under:		
Yun Yang Hsien	25,500,000	
Da Ning Hsien	9,900,000	
Kwei Chow Fu	2,700,000	
Yen Yuan Hsien	1,300,000	
Total shallow		39,400,000
Grand total		469,500,000

Changing the above figures to American tons we get the following table:

Type of Well	Tons of Salt	Per Cent of Total
Deep wells over 3000 ft. deep	182,600	58.3
Medium wells, mostly about 1000 ft.	104,100	33.3
Shallow wells, mostly under 200 ft.	26,300	8.4
Total	313,000	100.0

The value of the 313,000 tons of salt at 2 cents per pound is $12,520,000, which is a considerable yearly business even in U. S. A., and means a very large business in a country like China. It would be hard to estimate accurately the number employed in this industry, but it cannot be far from 1,000,000 hands.

The Milling Practice of the St. Joseph Lead Co.*

BY L. A. DELANO,[1] E. M.

During 1916, the St. Joseph Lead Co. milled 2,505,670 tons of ore. This is a daily operating average of 7855 tons. The economic concentration of such a large tonnage necessarily requires a plant equipped with modern machinery and operated efficiently. The milling process used in producing this output has been a gradual development through the long period of years that the company has been in existence.

*A paper to be presented at the St. Louis meeting of the American Institute of Mining Engineers, October, 1917.
[1]Mill Superintendent, St. Joseph Lead Co.
[2]Trans. A. I. M. E. (1888-89), 17, 659.

HISTORICAL SUMMARY OF MILLING PRACTICE

Ore was first mined at Bonne Terre, Mo., in 1864. The early milling practice was crude. It consisted of breaking the ore into small pieces by hand, pulverizing in a Blake crusher and a pair of Cornish rolls to approximately minus 6 mm., and jigging in the old-fashioned hand jigs. Only the coarse heavy galena was saved, the gangue being shoveled off and discarded. The output for the first year under this method was only 240 tons of pig lead.

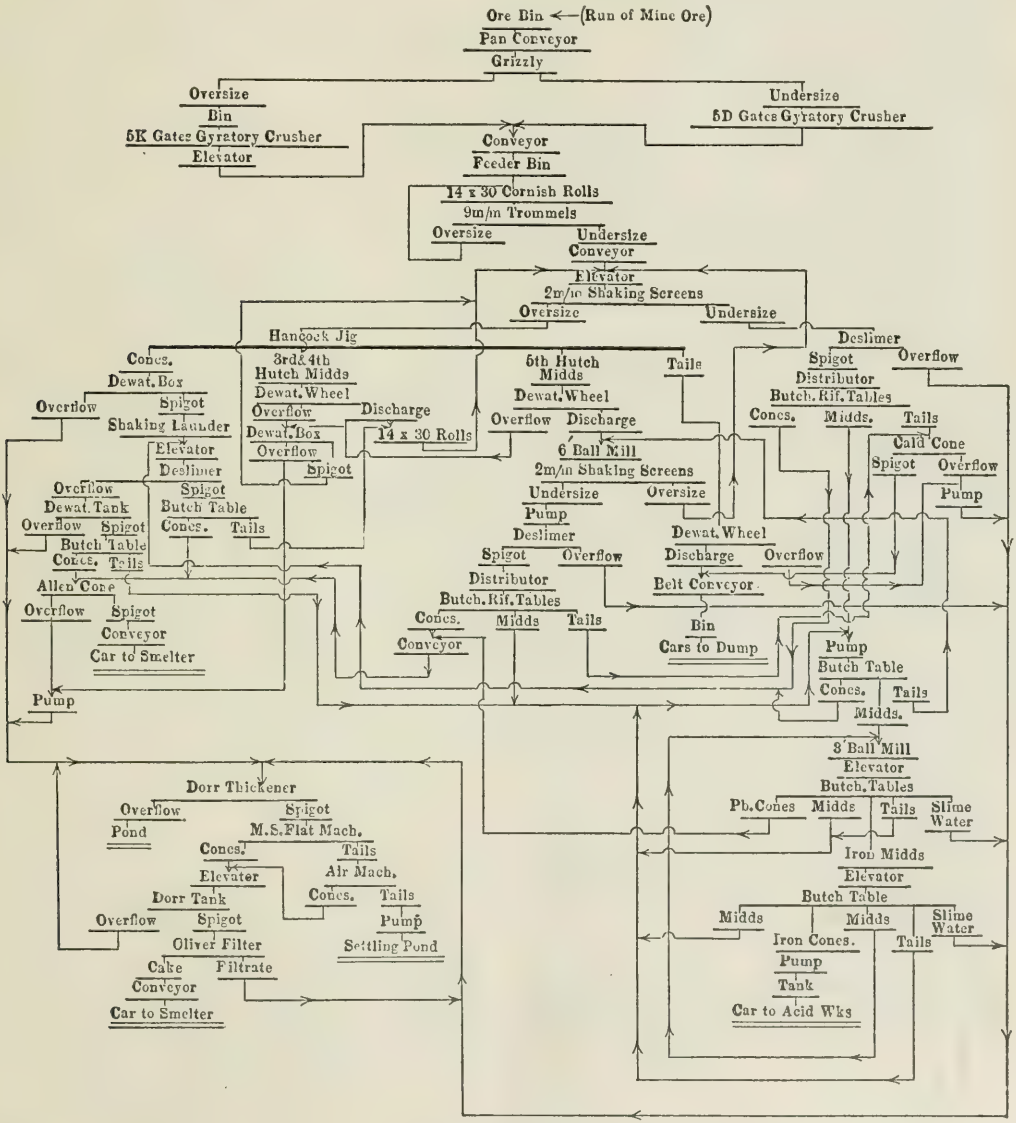

FIG. 1—FLOW SHEET BONNE TERRE MILL

The first mill of the company was a combination of extensions and additions built from time to time as the mines developed. It was a museum of early milling machinery, such as jigs, percussion tables, buddles, dolly tubs, log washers, etc., following no definite flow sheet. The chats, or tailings, were hauled to waste dumps by mule and ox teams, as much as 500 tons per day being moved in this manner, until a railroad was built in 1880. This mill was burned in 1883, at which time the annual output had reached approximately 7300 tons of pig lead.

A new mill of 500 tons capacity was designed and built by C. B. Parsons. This mill has been admirably described by H. S. Monroe.[2] The ore was crushed in Blake crushers, Cornish rolls, through 6-mm. screens, and treated by jigs of the Parsons type, percussion tables and log washers, or trunking machines, for cleaning the galena. The middlings were recrushed in rolls and treated on Harz jigs. The mill was operated without change, except later installing Gates crushers and enlarging the capacity to 1200 tons, until 1910, when Wilfley tables replaced those of the Rittinger type.

In 1904, a new mill was built at Leadwood, Mo., with a capacity of 1200 tons daily. The ore was crushed in Gates gyratory crushers and high-speed rolls, and concentrated on Harz jigs and Wilfley tables. In 1906, the Hancock jig was introduced to the district in this mill.

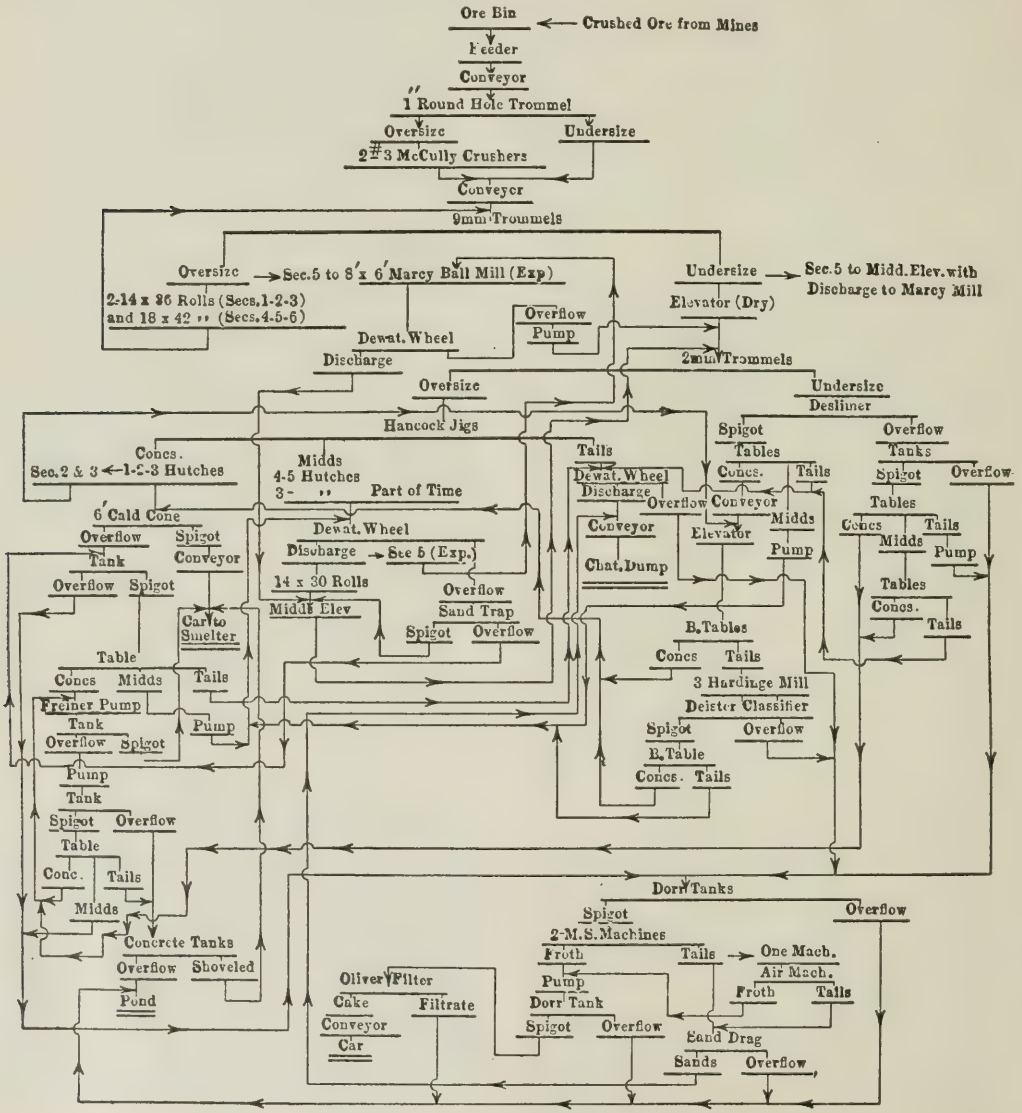

FIG. 2—FLOW SHEET OF D. R. L. CO.'S NO. 3 MILL, RIVER MINES, MO.

In 1909, the Doe Run Lead Co., now a subsidiary of the St. Joseph Lead Co., built a 2400-ton mill at Rivermines, Mo., which in 1913 was enlarged to handle 3600 tons per day. This plant received ore crushed to 4 in. at the mines, and, after reducing to 9 mm. at the mill, concentrated it on Hancock jigs and Wilfley tables.

In 1912, the Bonne Terre mill was partially remodeled, Hancock jigs, Richards classifiers, and automatic disposal of mineral and chat were installed, increasing the capacity of the plant to 1600 tons daily. In the spring of 1914, the flotation process having been applied to lead ores by the Federal Lead Co., it was installed in the three mills of this company for the treatment of the slimes. The application of modern crushing machinery, jigs, tables and flotation has resulted in the present system of milling with the ability to handle large tonnages economically.

DESCRIPTION OF THE PLANTS

The ores are milled at three plants, namely, Bonne Terre, Leadwood and Rivermines. Daily tonnages milled at each plant are: Bonne Terre, 2100; Leadwood, 1750; and Rivermines, 4000.

The mineral, galena, is disseminated in magnesian limestone or dolomite. It is associated with some pyrite, marcasite, chalcopyrite and sphalerite, and carries a small amount of silver. The ore in part of the mines runs high in chlorite (glauconite), and contains a rather large percentage of insolubles. The galena is massive, crystalline to fine granular in character and disseminated in the dolomite. The ore has a specific gravity of approximately 2.8, and a hardness of 3.5.

The flow sheets of the three mills are shown in Figs. 1, 2 and 3. In this paper a complete description of the Bonne Terre mill practice will be given, and then contrasted with the operation at the Leadwood and Rivermines mills, showing the principal differences in each plant.

THE BONNE TERRE MILL

The ore is hoisted to a bin of approximately 22 tons capacity. From this bin it is conveyed by pan conveyors to two No. 5 style D Gates and one No. 5 style K Gates gyratory crushers. A screen analysis of run-of-mine ore feeding the crushers is shown in Table 1.

TABLE 1—SCREEN ANALYSIS OF ORE AT THE BONNE TERRE MILL

Size	Per Cent Weight
On 10 mesh	11.1
On 8 mesh	12.6
On 6 mesh	7.6
On 4 mesh	32.5
Through 4 mesh	36.2
Total	100.0

Grizzlies with bars spaced with 7½-in. clearance are set on an incline over the two No. 5 D crushers that crush the undersize. The oversize gravitates to a small bin and is crushed by the No. 5 K crusher, and is then elevated by bucket elevator to pan conveyors, which convey all the crushed discharge to belt conveyors. These belt conveyors distribute the ore to feeder bins, scrapers being used to rake it off into each bin. Messiter electric scales attached to the pan conveyors receiving the discharge from the crushers were used for a time, but have been discontinued because of difficulty in keeping them accurately regulated. Table 2 shows a screen analysis of the crusher discharge.

TABLE 2—SCREEN ANALYSIS OF CRUSHER DISCHARGE

		−150 mesh	1.6
		Total	100.0

The same Cornish rolls that were installed in the mill when it was built in 1883 are still in use. Thirteen sets are used, fed by Challenge feeders. The shells are 14 by 30 in., one chilled cast iron and the other chilled steel is used on each set. A groove ¾ in. deep and 1½ in. wide is cut across the face of each steel roll shell to prevent slipping of the ore and consequent grooving of the shell. The roll speed is 10 r.p.m. Weight boxes are used on the rolls instead of springs. The roll discharge is screened through a 9-mm. trommel, 3 ft. diameter by 8 ft. long, with a slope of 1 in. per foot. The trommel revolves at a speed of 36 r.p.m. The oversize is returned by a bucket elevator to each roll. The rolls average 185 tons per 24 hr., and have shown by test that 250 tons per hour can be maintained. The rolls are driven by two 75-hp. and one 100-hp. motors with a total load of 210 hp., or an average of 16 hp. per roll, including the oversize return elevator.

THE CONCENTRATION SYSTEM

The mill is divided into four sections after crushing the ore, an equal tonnage being treated in each section. The mill building is built on a level site and it is necessary to elevate and pump the various products for treatment. All line shafts are near the basement floor, together with the rolls and other heavy machinery, set on concrete foundations. The undersize from the 9-mm. trommels is conveyed to elevators and water added to sluice the ore into the boots. The elevators are 53-ft. centers, using 8 by 16-in. buckets with a belt speed of 400 ft. per minute. The discharge from the elevators is screened on 2-mm. screens.

The screens are of the Ferraris shaking type, first used by the Desloge Lead Co. in this district, but have been redesigned at Bonne Terre to withstand the service required and to fit the limited head room. The screens are made at the plant, and cost about $125 each, erected. Three screens are used at each elevator, driven separately from a line shaft, so that repairs can be made, or screen sheets changed, while the other two carry the load. The screen frame is supported by hickory hangers set at an angle of 65 deg. to the frame. The drive-rod is connected to the head of the screen and a jig eccentric on a countershaft over the screen supports. The eccentric is set for 1¼-in. stroke and a speed of 270 to 290 r.p.m. A clear-water spray is used over the screen near the center to wash the fines from the oversize. Various screen openings have been tried, but at present 2-mm. round holes in No. 18 gage sheets are used, the sheets lasting about 40 days. Each screen treats 250 to 300 tons per 24 hours and requires 0.75 hp.

THE JIG INSTALLATION

The Hancock jigs treat the oversize of the 2-mm. screens. They are divided into five hutches and a tail compartment. The first and second hutches produce

concentrates, sent to the recleaning system. The third hutch is arranged for sending its product either to the concentrates or the middlings. The fourth and fifth hutches produce middlings. The camshaft has a speed of 65 r.p.m., giving the jig 195 strokes per minute. The horizontal throw averages ¾ in. and the vertical throw about ⅝ in. The tailings are dewatered by drag scrapers in the last compartments in order to separate them from the slimy water that overflows the jig and goes to the Dorr thickeners. The jig tailings are then sluiced to concrete tanks and dewatered by shovel wheels, the discharge going to a belt conveyor and concrete bin. These shovel wheels are 14 ft. in diameter, and make 1 r.p.m., the discharge averaging 15 per cent moisture.

The third and fourth hutch middlings are dewatered by a shovel wheel and recrushed by rolls, returning to the jig elevator and 2-mm. screens. These middlings are crushed to an average of 3 mm., releasing the galena in as coarse a size as possible.

THE BALL MILLS IN USE

A 6 ft. by 22 in. Hardinge mill crushes the middlings in section 1, and a 6 by 4 ft. Allis-Chalmers granulator is installed in section 3. They are being tested for results before placing mills in the other two sections.

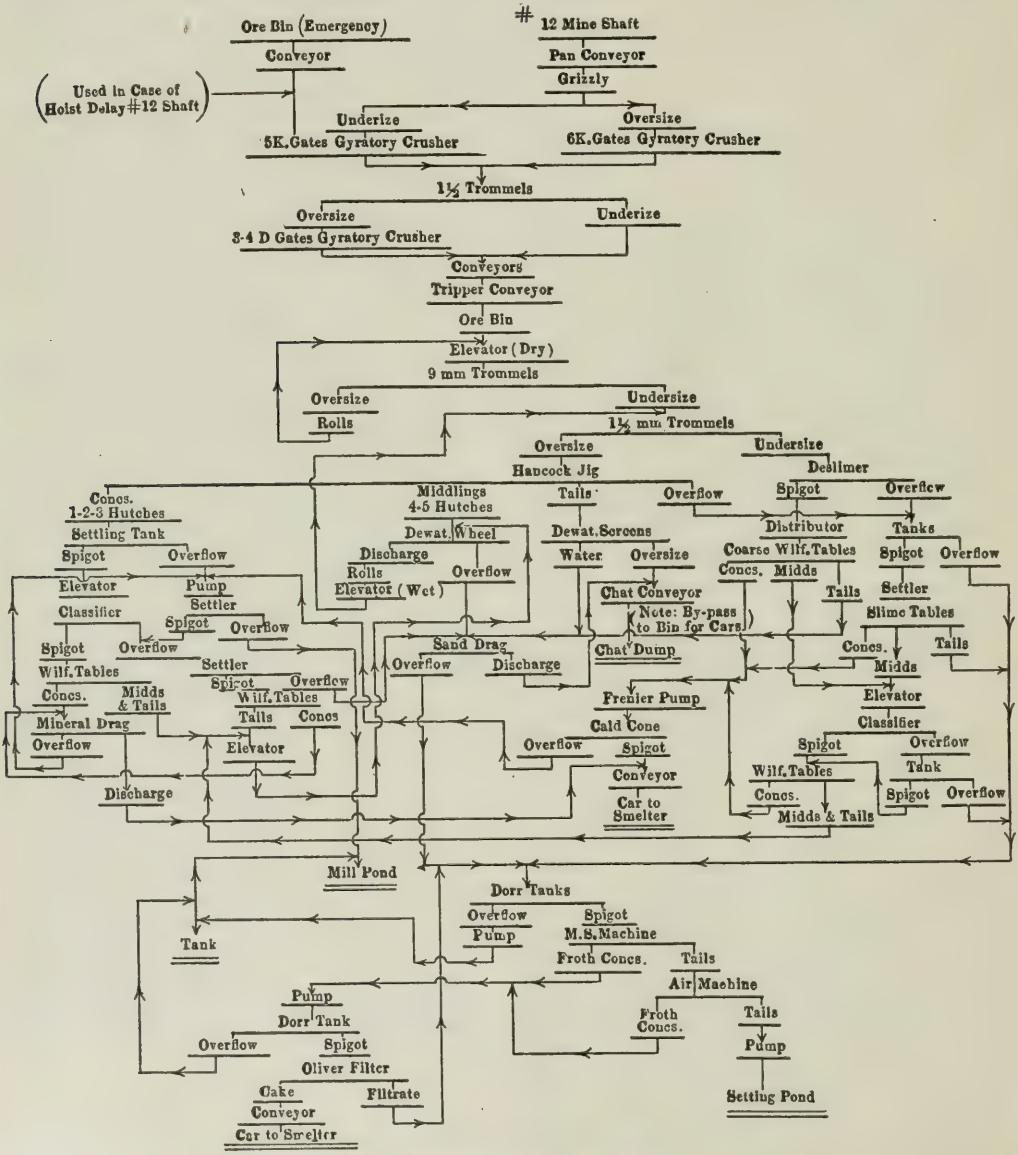

FIG. 3—LEADWOOD MILL FLOW SHEET

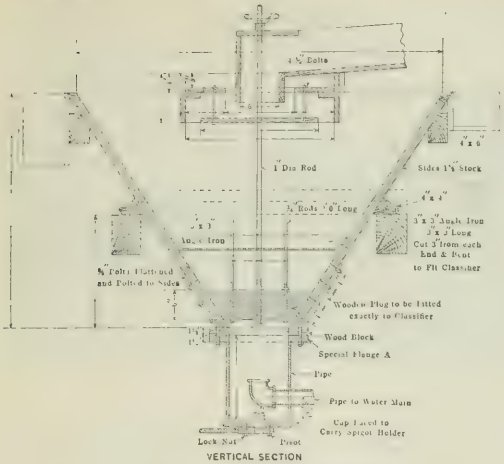

FIG. 4—THE DELANO DESLIMER

As final results had not been worked out on either type of mill at the time of writing, it is possible to give only some of the experimental data at present, showing the grinding efficiency and tonnages treated by each mill.

Results with the Hardinge mill are shown in Table 3.

TABLE 3—*Data on Hardinge Mill Operation*

Average tonnage ground	250 tons per 24 hr. (this includes 50 tons of middlings returned from table treatment).
Ball load	14,000 lb.
Kind of balls	Cast iron, with 3 in. maximum diameter.
Power required	53 hp.
Speed of mill	30 r.p.m.
Moisture	50 per cent.
Ball consumption	0.9 lb. per ton crushed

The following screen analysis in Table 4 shows the crushing performed on this class of material.

The discharge from the mill is screened through a 2-mm. shaking screen. The oversize returns to the jig elevator as jig feed, and the undersize is pumped to a deslimer for table and flotation treatment.

Various tests have been tried in crushing by the Hardinge mill, *e.g.*, crushing the entire middlings, returning the oversize to the jig and the undersize to tables and flotation. This method enriched the flotation feed too much, due to the rich middlings from the third and fourth hutches of the jig. Another test was to crush the entire tailings of the jig, the middlings being crushed in the rolls and returning to the elevator, and the oversize of tailings from the ball mill being discarded as chat. The ball mill lacked capacity to treat the necessary tonnage in this manner, and it was found that the most economical method was to crush the middlings from the fifth hutch of the jig. This gave low tailings on the jig and low-grade slime for flotation, besides allowing a larger tonnage of ore to be treated in the mill section.

THE ALLIS-CHALMERS GRANULATOR

This mill has a grate through which the crushed product must pass before being discharged. As with the Hardinge mill, various tests are being made to determine its crushing capacity, efficiency, etc. The first tests were to crush the jig tails, cast-iron balls with 3-in. maximum diameter being used as grinding mediums. Ball loads ranged from 9000 lb. to 14,000 lb., but the results were not satisfactory, the tonnage building up in the mill and choking it. Raising the pulp level improved the grinding slightly. It was found, however, that the balls broke up badly, so a change was made to forge chrome-steel balls of large diameter. Tests for ball charges, load and pulp level have resulted in gradually raising the tonnage of feed and grinding efficiency. The results shown in Table 5 are the best that have been obtained as yet, further tests being made with a closed circuit.

The discharge from the mill for a while was screened through a 2-mm. screen, the oversize being discarded as chat. Later a 3-mm. screen was substituted, resulting in the table tailings averaging practically the same as with the smaller opening. The oversize of this screen was also discarded, but is now being returned to the jig feed, making a closed circuit on the ball mill. Results from this at present are not complete.

TABLE 5—ALLIS-CHALMERS BALL GRANULATOR RESULTS

Character of feed	Jig tails and fifth-hutch middlings
Ball load	12,000 lb. (consisting of 100 lb. of 5 in. diam., 3000 lb. of 4 in. diam., 8000 lb. of 3 in. diam.)

SUMMARY OF BALL MILL PRACTICE

It is impossible now to give final results metallurgically as to the effect of ball mills on the milling practice of the ores. However, an increased capacity for the plant is obtained when the middlings are taken from their former closed circuit with the jig and recrushed in ball mills. The undersize of the ball-mill discharge is deslimed, the sands going to separate tables. This gives the jig capacity for more original ore, and the plant now handles 2300 to 2400 tons per day. This

FIG. 5—DOE RUN LEAD CO.'S MILL, RIVERMINES, MO.

alone has justified the installation of the ball mill. On the other hand, rolls cannot grind the low-grade middling as well as the ball mill, the latter giving more material for tables and flotation, which result in lower tailings than the jigs. The regrinding of jig tailings has resulted in lowering the final tailings. Approximately 60 per cent of the feed to the Allis-Chalmers ball mill is sent to tables, the tailings of which average less than 0.4 per cent Pb. The flotation plant receives 18 per cent of the feed and will make minimum tailings there. The tests have not been completed to show the economic effect of lowering the mill tailings, but the results point toward a profit, even with a low-price lead.

TABLE CONCENTRATION

In the summer of 1915, it was decided by the management to give the Butchart riffling a trial in table practice, in order to increase the tonnage and efficiency of the mills. A series of tests were carried out for several months at the Bonne Terre mill to determine the best application of the riffle to the treatment of these ores.

Previous to this time, Wilfley tables and riffling had been used, the feed to the tables being the spigot products of Richards four-spigot, vortex classifiers. The Butchart riffling worked best, however, with deslimed sands, no separation into different sizes being required. As it became necessary to mix the spigot products of the classifiers, it was decided to change the classification system.

Experiments were conducted to produce a one-spigot classifier that would handle the entire tonnage of the undersize from the 2-mm. shaking screens and deslime it so as to give a table feed practically free from the minus 150-mesh slimes. The experiments resulted in a one-spigot, two-product, hydraulic classifier, or deslimer, with an inverted conical or pyramidal tank, the entire perimeter being used for the overflow into a surrounding launder at the upper edge. The deslimer is provided with a central feed box, having a baffled bottom to break the velocity of the inflowing pulp. The bottom, or discharge chamber, has a clear-water inlet, which directs the flow upward along the axis of the deslimer. The spigot is inserted in a movable holder, attached to the bottom of the discharge chamber, permitting an instant change in the diameter of opening without wetting the operator. Between the feed box and discharge chamber is a valve with sides parallel to the tank and suspended on the vertical center, and which can be raised or lowered by means of a hand wheel on the suspension rod. This produces a narrow channel between the valve and tank through which the hydraulic water rises and the sands fall.

The feed entering the deslimer is checked by the baffle, causing the sands to settle through a narrow, rising current of water surrounding the valve. This current increases in velocity until the discharge chamber is reached, by which time the sands are thoroughly deslimed. A hydraulic pressure of 5 or 6 lb. per square inch is maintained in the discharge chamber. The width of the sorting column may be varied by raising or lowering the valve. No whirling or boiling currents are possible and the steady rising current gives a very close separation. The great efficiency of the deslimer is due to the better application and direction of hydraulic water supplied. A deslimer 5 ft. 6 in. in diameter treats from 350 to 400 tons per 24 hours, using approximately 120 gal. of hydraulic water per minute.

Table 6—Screen Analyses of Deslimer Material

Mesh	Feed, Per Cent Weight	Spigot, per Cent Weight	Overflow, per Cent Weight
On 100	64.70	86.8	0.69
On 150	7.41	8.2	5.16
On 200	4.10	2.3	9.32
Through 200	23.79	2.7	84.83
Total	100.00	100.00	100 00

Experiments with the Butchart riffling were carried out with the following objects in view, viz., to determine size and character of feed, to increase the table efficiency, increase its capacity, simplify the flow sheet, reduce water consumption, power and labor. Its ability to treat unclassified material gave it advantages over the Wilfley riffling by eliminating the multiple-spigot classifier. The concentrates are discharged at the upper edge of the table, the coarser particles being in the upper riffles instead of mixing with the middlings, as in the Wilfley riffling. This gives a larger capacity for both the concentrates and middlings separation and enables much larger tonnages to be treated per table.

Tests were made with feed ranging from minus 9 mm., or jig feed, to the finest sands. In each case the

FIG. 5—DOE RUN LEAD CO.'S MILL, RIVERMINES, MO.

riffling was made especially for the size of feed treated. The separation of free galena as concentrates in each case was satisfactory, but in the coarser sizes the separation of the middlings from the gangue was imperfect and would have necessitated recrushing the entire tailings for retreatment. Final tests showed that the jigs gave a better separation of tailings and middlings on material from 9 to 2 mm., while the undersize of 2-mm. screens deslimed to remove the minus 150-mesh slimes, and treated on tables, gave satisfactory results.

With this size of feed the tables now treat from 50 to 60 tons per day, giving clean concentrates and as low tailings as with the Wilfley when treating 20 to 25 tons per day. In operation, the table requires very little adjustment, even with the load varying 5 or 10 tons. The riffling used in this work tapers from 7/16 in. to ⅛ in., with a slope of 1 in 4 in the cleaning zone. The middlings average approximately 10 per cent of the feed to the tables. This is retreated on a separate table for two mill sections, the tailings being reground in the 6-ft. ball mill. A concentrate cut is made from this table and the middlings are reground in a 3-ft. Hardinge mill and sent to another circuit.

In changing the mill from the Wilfley to the Butchart system, one Butchart table replaced three Wilfley tables, and resulted in a saving in power, labor and water. Various pumps, launders, classifiers and settling tanks were also cut out, making a much simpler flow sheet in this mill.

The possibility of using the Butchart riffling to raise the grade of the mill concentrates was suggested by its large capacity and its ability to treat coarse material, discharging the coarsest particles at the upper edge of the table. The jig concentrates were erratic, ranging from 60 to 70 per cent Pb, and occasionally going lower. Before this they had been washed in a log washer or trunking machine, which made a rather poor separation. Tests with the Butchart riffling showed that the feed should be deslimed and treated on two tables. The spigot of the deslimer—or plus 100-mesh material—was treated on one table, and the overflow, or minus 100-mesh material, was settled in a tank, the spigot feeding the second table.

Table concentrates were mixed with the jig concentrates to produce a mixture of sizes that would bed well on the table. The riffling on each table was especially arranged for the size and character of the feed. The coarse galena was discharged in the upper riffles, followed by the finer sizes. A good separation was made in the cleaning zone, the tailings constituting true middlings containing practically no free galena. They averaged 25 to 35 per cent, and are recrushed in the jig-middling rolls, returning to the circuit by the jig elevator. The coarse table now treats from 70 to 100 tons per day and has capacity for a larger range in tonnage.

The fine-table concentrates averaged 80 per cent Pb, 95 per cent passing a 200-mesh screen. The tailings average 6 per cent Pb, and are returned to the sand middlings table.

At present the entire jig concentrates and a portion of those from the tables are treated in the recleaning system. The grade of the mill concentrates has been raised from an average of 68 per cent to 73.5 per cent, resulting in smaller freight and smelter treatment charges, and without affecting the mill recovery.

CONCENTRATES DISPOSAL

The concentrates from the entire mill are sent to a 60-ft. Allen cone for dewatering. The spigot discharges on a conveyor belt to the car, while the overflow returns to the mineral elevator.

The jig-tailings disposal was referred to in describing the jigging. The tailings from the tables are dewatered by Caldecott cones, the sands discharging through the spigot to the chat conveyor. The cones will average from 400 to 500 tons of minus 2-mm. sands per day, the average moisture in spigot being 28 per

FIG. 6—FLOTATION MACHINE, RIVERMINES MILL

FIG. 7—ST. JOSEPH LEAD CO.'S BONNE TERRE PLANT

cent. A screen analysis of the spigot discharge is shown in Table 7.

TABLE 7 -CALDECOTT CONE SPIGOT DISCHARGE

Mesh	Per Cent. Weight	Mesh	Per Cent. Weight
+10	2.59	+65	7.27
+14	9.61	+100	6.65
+20	17.64	+150	5.18
+28	22.95	+200	1.25
+35	15.13	−200	0.86
+48	10.87		
		Total	100.00

The sands from these cones, and the shovel-wheel discharge, or jig tailings, are conveyed by a 20-in. conveyor to a concrete chat bin with a capacity of 250 tons. Railroad cars of the A-dump type run under this bin, and are loaded by slide gates in the bottom of the bin, and sent to the chat dump. A portion is sold for railroad ballasting and concrete work.

THE PYRITES CONCENTRATES

The ore assays approximately 5 per cent Fe, consisting mainly of pyrite, marcasite and chalcopyrite. This is concentrated in the table middlings and requires fine grinding to separate the galena, pyrite and dolomite. The middlings from the sand tables are reconcentrated on a middling table and the middlings from this table are sent to a 3-ft. Hardinge mill for regrinding. The mill is operated with a 1000-lb. ball load, replenished with 2-in. cast-iron balls. The product will nearly all pass a 65-mesh screen, and is elevated to a Butchart table. Lead concentrates, assaying 80 per cent, are sent to the Allen cone and middlings are retreated on another Butchart table, which produces galena-pyrites concentrates. The analysis of concentrates shows an average of 41 per cent sulphur, a portion being shipped to a sulphuric-acid plant for experimental purposes, with a view to recovering the sulphur as acid. The remainder is mixed with the galena concentrates and is shipped to the St. Joseph Lead Co.'s smeltery at Herculaneum for its value as an iron flux.

TREATMENT OF SLIMES

The overflow of the deslimers, chat-wheel pits, Caldecott cones and various small settling boxes, is thickened in five Dorr tanks, four of which are 40 by 8 ft., and one 50 by 6 ft. The feed to these tanks averages 2.5 per cent solids, the total flow being approximately 3500 gal. per minute. The solids average 540 tons per 24 hours, or approximately 12 sq. ft. of settling area per ton of dry slime. The central shafts revolves once in 10 min. The overflow from the tanks returns to the

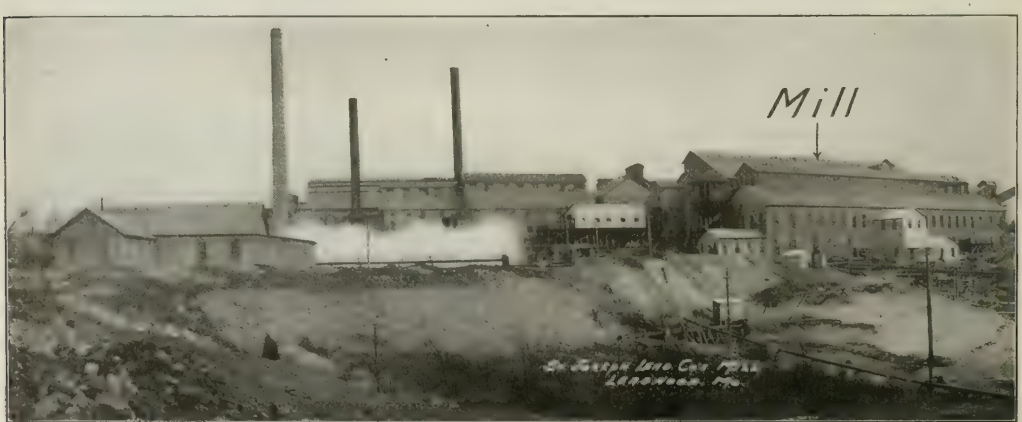

FIG. 8—ST. JOSEPH LEAD CO.'S MILL, LEADWOOD, MO.

mill pond for use as mill wash water, while the spigot discharge is sent to the flotation machine.

The thickened pulp at a ratio of 2.5 to 3.0:1 is treated in a 23-cell Minerals Separation flotation machine, with 24-in. agitating compartments. Creosote oil (hardwood) is added in the feed box and at several alternate cells, a small oil pump being used to give a regular oil feed. The impellors are belt driven from a line shaft, the speed being 335 r.p.m.

The machine is driven by a 100-hp. motor using 83 hp., or an average of 3.8 hp. per cell. The tailings from this machine are retreated in a pneumatic machine. The froth, or concentrates, averaging 50 per cent Pb from both machines, are elevated by a bucket elevator to a Dorr thickener.

Oil consumption averages 0.55 lb. per ton of dry slimes treated. The slimes average 540 tons per day, or, at present, 23 per cent of the ore milled. This percentage is higher than in the other mills of the company, due principally to the use of Cornish rolls and the larger proportion of reground middlings.

CONCENTRATES DISPOSAL

The froth is broken up by clear-water sprays and thickened in a 38 by 6-ft. Dorr tank. The overflow goes to the slimes tanks and the spigot discharge, averaging 60 per cent solids, is sent to a 12-ft. by 11-ft. 6-in. Oliver filter. The Dorr-thickener feed averages 90 per cent moisture. A permanent froth remains on the surface and is kept from overflowing by a baffle ring 12 in. inside the overflow and 12 in. above and below the surface of the water. The central shaft revolves twice per hour.

The cake from the Oliver filter averages 15 per cent moisture, and is conveyed by belt conveyor to cars and shipped to the smelter. At present a portion of this cake is dried in vats fitted with steam coils, to a moisture of 7 per cent, in order to enable the smelter to handle the output. The filtrate returns to the slimes thickeners. The filter speed is one revolution in 6 min. and 30 sec. The wet cake averages approximately 50 tons per 24 hours. One "blow" compartment is maintained about 6 in. above the scraper, the other compartment blowing after immersion in the pulp, which is kept at a maximum level. The blow pressure ranges from 5 to 10 lb. The vacuum is produced by a No. 5 Root pump, averaging 25 to 20 in. The vacuum requires 29.5 hp. and the filter 1.7 hp. The life of a canvas and burlap averages 3 months. After a new canvas is in use from 4 to 6 weeks, steam is exhausted in the pulp for the purpose of heating. This gives a larger capacity without increasing the moisture in the cake. Acid washes have been tried for the canvas without success.

The tailings from the flotation machines are pumped by a 3-in. Morris sand-dredge pump to the impounding pond, against a total head of 50 ft., using 18 hp. The pond dam is built of chat hauled from the mill and is 50 ft. high at its maximum point. The flow of pulp averages 225 gal. per minute, and immediately spreads over the surface of the pond, allowing the solids to settle rapidly. No water remains on the surface, as it filters rapidly through the chat dam. Consequently the pond will eventually fill up in layers, forming a smooth dry body of compact slime. The filtered water is perfectly clear and free from slime.

The mill water is returned to a pond with an area of 17,000 sq. ft., formerly used for settling the mill slimes before the installation of Dorr tanks. Any slimes now escaping the Dorr tanks are caught in this pond and pumped back periodically for retreatment. The volume of water used in the mill circuit is approximately 3500 gal. per minute, or a ratio of 9:1. This compares with a ratio of 17:1 before the change was made in table practice, classification, etc. Loss in mill water, due to waste of flotation tailings, etc., is made up of mine water and from a pumping station on Big River, 3 miles away.

All machinery in the mill is electrically driven, using an average of 7.29 kw. per ton of ore treated. With the present tonnage treated this equals approximately 925 hp. As much machinery as possible is driven by individual motors, even some of the tables using separate 1-hp. motors. All motors are loaded to capacity to obtain greatest efficiency.

The labor in the mill is all American and much more efficient than a few years ago. The tons of ore milled for 1916 averaged 25 per man shift, including maintenance, with an average of 84 men employed per day. Three shifts are operated per day, 6 days a week, Sundays

FIG. 8—ST. JOSEPH LEAD CO.'S MILL, LEADWOOD, MO.

being used for repairs. The mill recovery varies with the grade of ore, the tailings from the plant being equal to the district average. Future improvements will probably include larger crushers, substitution of other grinding machinery for the Cornish rolls, and extension of table and flotation equipment, with the view of raising the tonnage, recovery, and the cheapening of costs.

THE RIVERMINES MILL

The Rivermines mill is divided into six sections. The ore is crushed to 4 in. at the mine shafts and hauled in A-dump cars by railroad to a large storage bin extending across the mill end. This bin has a capacity of 3500 tons or sufficient for nearly a day's run. A trestle extends beyond the bin, so that the cars may be pinched down grade over the bin and emptied. In winter, steam nozzles are used to thaw the ore sufficiently for unloading. All the ore is weighed on scales on this trestle.

The ore is fed from the bin by roller feeders, operated by a gripping cam, to 1-in. round-hole trommels, 8 ft. long by 24 in. in diameter. The oversize of these trommels is crushed by two No. 3 McCully gyratory crushers, the crusher discharge joining the undersize from the trommels and is carried by belt conveyor to two 48-in. by 12-ft. trommels with 9-mm. round holes. The oversize from these trommels is recrushed by rolls. The discharge from the rolls returns to the conveyor feeding the 9-mm. trommels, the undersize of which goes to an elevator, which raises the dry ore to the 2-mm. trommels on the top floor. From this point the milling practice is practically the same as at the Bonne Terre mill.

THE MARCY MILL

An 8 by 6-ft. Marcy ball mill has been installed in section 5 for experimental purposes. This mill has been tried in various tests and is now crushing the oversize from the 9-mm. trommels and the dewatered middlings from the fourth and fifth hutches of the Hancock jig. The discharge from the ball mill goes to the 2-mm. trommels, the oversize feeding the jig and the undersize the tables and flotation plant. As in the Bonne Terre mill, final results have not been worked out on this mill. As it is a grate-type mill, the results are similar to those of the Allis-Chalmers granulator. In this case 73 per cent of the feed to the mill is the oversize of the 9-mm. trommels, the balance being middlings from the jigs and tables, the total averaging 750 tons per day. Approximately 200 hp. is required, the mill using a ball load of 28,000 lb. of 5, 4 and 3-in. balls; 5-in. balls being used for replenishing. The average moisture is 65 per cent. Screen analyses of the feed and discharge product are shown in Table 8.

The jig tailings are dewatered in chat wheels as at Bonne Terre, and the table tailings in sand cones and a sand drag. They are then stacked by belt conveyors, forming a very large tailings pile, which has accumulated since the plant started.

The tailings from the flotation plant are pumped by a 5-in. Morris sand-dredge pump to the top of the chat pile and is used for spreading the chat from the conveyors.

The mill water is settled in a pond back of the plant and is pumped from there to a reservoir situated at a maximum elevation in front of the building, from which it is reused in the mill circuits. The volume of water used is approximately 5000 gal. per minute, or a ratio of 7:1 of ore.

Table 8—Marcy Mill Results

Feed				Discharge			
Mesh On	Per Cent. Weight	Cumulative per Cent. Weight	Per Cent Total Pb Content	Mesh On	Per Cent. Weight	Cumulative per Cent. Weight	Per Cent Total Pb Content

Total..	100.0	.....	100.0	−200	14.7	100.0	31.6
				Total....	100.0	.. ....	100.0

All power is alternating current, an average of 8.24 kw. is used per ton of ore treated. The labor is all American. This mill will be rearranged later with ball mills for reducing the general tailings and increasing the capacity.

THE LEADWOOD MILL

The Leadwood mill has practically the same milling operations as at the Bonne Terre and Rivermines plants. All the ore is hoisted from No. 12 mine shaft at the mill and is conveyed direct to the crushers. In case the hoist should be out of commission for any reason, the ore from the outlying shafts can be diverted to an ore bin from which it is conveyed to the 5 K Gates crusher, thus preventing an entire shutdown of the mill.

The regular ore feed is screened on a grizzly with bars spaced 8 in. apart. The undersize is crushed in the 5 K crusher and the oversize in the 6 K crusher. The discharge from these crushers is screened through 1½-in. trommels, the oversize being recrushed in three No. 5 D Gates crushers. From here it is conveyed to an ore bin of 1600 tons capacity, and distributed by a tripper on the conveyor.

The ore from the bin is screened through 9-mm. trommels. The oversize is recrushed by rolls and returned to the 9-mm. screens. The undersize is screened through 1½-mm. trommels. From this point the concentration is practically the same as at Bonne Terre and Rivermines.

The jig tailings discharge in the bottom of the tail hutch of the jig and fall over stationary 1½-mm. screens. The oversize discharges on the chat conveyor, while the water drains to the sand drag. Wilfley tables, a portion Butchart riffled, are used for sand concentration. The minus 1½-mm. and plus 150-mesh sands are treated on the coarse tables, the tailings going to a concentrates pit. A drag scraper in this pit dewaters the sands and discharges them on the chat belt with 15 per cent moisture. This drag gives some trouble by breaking, but manganese-steel link chains are now being used in order to reduce this to a minimum.

The fine sands, minus 150-mesh, and slimes are thickened in settlers and concentrated on Wilfley tables, the tailings going to the Dorr tanks at the flotation plant. The overflow of the sand drag also goes to the flotation plant. The slimes are thickened in four 36 by 8-ft.

Dorr thickeners. The pulp is agitated in a 16-cell Minerals Separation flotation machine, the same oil being used as at the other mills. The tailings are retreated by an air machine, and the concentrates are thickened and filtered by an Oliver filter. The flotation plant is lightly loaded, approximately 350 tons dry slimes, and the concentrates produced average 58 per cent Pb. The slime tailings are pumped to a settling pond behind the chat dump and settle as at Bonne Terre.

The mill chat, jig and table tailings are conveyed by belt conveyor to a tailings pile. This conveyor inclines at an angle of 26 deg. and the chat is sufficiently dry not to cause any slippage on the belt, which is not cupped.

This mill will be equipped with ball mills for regrinding middlings and tailings as at Bonne Terre. A 6 by 4-ft. Allis-Chalmers ball granulator is installed in one section, but has not started operating, so no data can be given. A 3-ft. Hardinge mill is installed for regrinding table middlings as at Bonne Terre, but is just starting operation, and no results are obtainable. The Leadwood ores contain considerable zinc sulphides, which will probably concentrate in this circuit.

The milling practice of the St. Joseph Lead Co. is passing through a transitory stage. Considerable experimental work is being done at each plant, a thoroughly equipped laboratory being maintained at each mill. While large tonnages are being treated in the three plants with the highest recoveries obtainable, it is probable that the introduction of ball mills and further extension of flotation equipment will greatly change the present practice.

Bonne Terre, Mo.

Motion Pictures at the Exposition

MONDAY, SEPT. 24

Evening—8.00 p. m.

1. Hydraulic power development (4 reels).
2. Making a giant steam turbine (General Electric Co., 1 reel).
   (a) Handling pig iron.
   (b) Filling the cupola and pouring castings.
   (c) Machining and assembling the castings.
3. Generation of electric power (2 reels).
4. Transmission of electric power (1 reel).
5. The fixation of atmospheric nitrogen by electricity at Niagara Falls and feeding the soil with the products (American Cyanamid Co. 2 reels).
6. The king of the rails, or the evolution of transportation (General Electric Co., 3 reels).

TUESDAY, SEPT. 25

Afternoon—2 p. m.

1. Carpet weaving (1 reel).
2. Manufacture and use of wool and its products (2 reels).
3. Cotton as a source of wealth—growing and manufacturing its products (3 reels).
4. The manufacture of leather and its products (1 reel).
   (a) Tanning.
   (b) Working up leather.
   (c) Manufacturing of shoes.
5. The manufacture of glass (3 reels).

Evening—

Production of spelter and manufacture of lead products (5 reels and stereopticons showing eighteen months' development).

(a) Mining zinc and lead ore in Oklahoma.
(b) Smelting for lead and zinc at Joplin and Henrietta.
(c) Production of sublimed lead pigment from the ore by the fume process.
(d) Manufacture of carbonate of lead for paint pigment.
(e) Manufacture of lead paints, accompanied by descriptive discussion by John R. MacGregor, assistant general sales manager Eagle-Picher Lead Co.

WEDNESDAY, SEPT. 26

Afternoon—2 p. m.

1. Manufacture of linen bond paper (1 reel).
2. The cordage industry (5 reels).
3. Manufacture of paint (3 reels).
4. The soap industry (1 reel).
5. The manufacture of perfumes "The Spirit of the Flowers" (1 reel).
6. Industrial plants on the Clinchfield Railway.

Evening—

1. The coal, coke and by-products industry (The Barrett Co., 2 reels).
   (a) Coal mining operations.
   (b) Old and new methods of coking coal.
   (c) Recovery of by-products.
   (d) Use and results from ammonium sulphate as a fertilizer.
2. The asphalt industry (Barber Asphalt Paving Co.).
   (a) Removing asphalt from Trinidad and Bermudez Lakes.
   (b) Transportation of raw asphalt.
   (c) Refining and manufacturing.
   (d) Building roads and streets.
   (e) Manufacture of prepared roofings and other products.
3. The petroleum industry—shooting the Lake View Gusher.

THURSDAY, SEPT. 27

Evening—The metal industries—

1. Copper leaching operations at the plant of the Chile Exploration Co., Chiquimata, Chile. (4 reels).
2. Silver—"The Treasure of the Incas" (2 reels).
3. Gold—"The Basis of Business" (1 reel).

FRIDAY, SEPT. 28

Afternoon—2 p. m.

1. Asbestos as fire protection (1 reel).
2. Building of roads and their maintenance (DuPont de Nemours Co., 2 reels).
3. Farming with dynamite (DuPont de Nemours Co., 1 reel).

SATURDAY, SEPT. 29

Afternoon—2 p. m.

1. The manufacture of Portland cement (1 reel).
2. Triumph of the ultramicroscope—seeing invisible colloid particles (1 reel).
3. The milk industry (2 reels).
4. Preparation of condensed milk (3 reels).

Evening—8 p. m.

1. The sugar industry (4 reels).
2. The flour industry (2 reels).
